The CTILAR bit assignments are:

#### KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

#### Accessing the CTILAR:

CTILAR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
CTI	0xFB0

H9.3.27 CTILSR, CTI Lock Status Register

The CTILSR characteristics are:

Purpose

Indicates the current status of the Software Lock for CTI registers.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

CTILSR is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software Lock can be implemented as part of CoreSight compliance.

CTILSR is RAZ if the Software Lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

Attributes

CTILSR is a 32-bit register.

Field descriptions

The CTILSR bit assignments are:

Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the Software Lock is implemented, possible values of this field are:

- 0 Lock clear. Writes are permitted to this component's registers.
- 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

When this register has an architecturally-defined reset value, this field resets to 1.

#### SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED.

Permitted values are:

- 0 Software Lock not implemented or not memory-mapped access.
- 1 Software Lock implemented and memory-mapped access.

#### Accessing the CTILSR:

CTILSR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
CTI	0xFB4

**H9.3.28 CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31**

The CTIOUTEN<n> characteristics are:

**Purpose**

Defines which input channels generate output trigger n.

**Usage constraints**

This register is accessible as follows:

SLK	Default
RO	RW

**Configurations**

CTIOUTEN<n> is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If output trigger n is not connected, the behavior of CTIOUTEN<n> is IMPLEMENTATION DEFINED.

**Attributes**

CTIOUTEN<n> is a 32-bit register.

**Field descriptions**

The CTIOUTEN<n> bit assignments are:

**OUTEN<x>, bit [x], for x = 0 to 31**

Input channel <x> to output trigger <n> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Possible values of this bit are:

- 0 An event on input channel <x> will not cause output trigger <n> to be asserted.
- 1 An event on input channel <x> will cause output trigger <n> to be asserted.

This field resets to a value that is architecturally UNKNOWN.

**Accessing the CTIOUTEN<n>:**

CTIOUTEN<n> can be accessed through the external debug interface:

Component	Offset
CTI	0x0A0 + 4n

### H9.3.29 CTIPIDR0, CTI Peripheral Identification Register 0

The CTIPIDR0 characteristics are:

#### Purpose

Provides information to identify a CTI component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

CTIPIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

#### Attributes

CTIPIDR0 is a 32-bit register.

#### Field descriptions

The CTIPIDR0 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PART\_0, bits [7:0]

Part number, least significant byte.

#### Accessing the CTIPIDR0:

CTIPIDR0 can be accessed through the external debug interface:

Component	Offset
CTI	0xFE0

**H9.3.30 CTIPIDR1, CTI Peripheral Identification Register 1**

The CTIPIDR1 characteristics are:

**Purpose**

Provides information to identify a CTI component.  
For more information see [About the Peripheral identification scheme on page K2-6146](#).

**Usage constraints**

This register is accessible as follows:

SLK	Default
RO	RO

**Configurations**

CTIPIDR1 is in the Debug power domain.  
Implementation of this register is OPTIONAL.  
This register is required for CoreSight compliance.

**Attributes**

CTIPIDR1 is a 32-bit register.

**Field descriptions**

The CTIPIDR1 bit assignments are:

31	8	7	4	3	0
RES0				DES_0	PART_1

**Bits [31:8]**

Reserved, RES0.

**DES\_0, bits [7:4]**

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.

**PART\_1, bits [3:0]**

Part number, most significant nibble.

**Accessing the CTIPIDR1:**

CTIPIDR1 can be accessed through the external debug interface:

Component	Offset
CTI	0xFE4

H9.3.31 CTIPIDR2, CTI Peripheral Identification Register 2

The CTIPIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.  
For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR2 is in the Debug power domain.  
Implementation of this register is OPTIONAL.  
This register is required for CoreSight compliance.

Attributes

CTIPIDR2 is a 32-bit register.

Field descriptions

The CTIPIDR2 bit assignments are:

Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES\_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

Accessing the CTIPIDR2:

CTIPIDR2 can be accessed through the external debug interface:

Component	Offset
CTI	0xFE8

### H9.3.32 CTIPIDR3, CTI Peripheral Identification Register 3

The CTIPIDR3 characteristics are:

**Purpose**

Provides information to identify a CTI component.  
For more information see [About the Peripheral identification scheme on page K2-6146](#).

**Usage constraints**

This register is accessible as follows:

SLK	Default
RO	RO

**Configurations**

CTIPIDR3 is in the Debug power domain.  
Implementation of this register is OPTIONAL.  
This register is required for CoreSight compliance.

**Attributes**

CTIPIDR3 is a 32-bit register.

**Field descriptions**

The CTIPIDR3 bit assignments are:

31	8	7	4	3	0
RES0				REVAND	CMOD

**Bits [31:8]**

Reserved, RES0.

**REVAND, bits [7:4]**

Part minor revision. Parts using CTIPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

**CMOD, bits [3:0]**

Customer modified. Indicates someone other than the Designer has modified the component.

**Accessing the CTIPIDR3:**

CTIPIDR3 can be accessed through the external debug interface:

Component	Offset
CTI	0xFEC

H9.3.33 CTIPIDR4, CTI Peripheral Identification Register 4

The CTIPIDR4 characteristics are:

Purpose

Provides information to identify a CTI component.  
For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR4 is in the Debug power domain.  
Implementation of this register is OPTIONAL.  
This register is required for CoreSight compliance.

Attributes

CTIPIDR4 is a 32-bit register.

Field descriptions

The CTIPIDR4 bit assignments are:

31	8	7	4	3	0
RES0				SIZE	DES_2

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log<sub>2</sub> of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES\_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

Accessing the CTIPIDR4:

CTIPIDR4 can be accessed through the external debug interface:

Component	Offset
CTI	0xFD0

### H9.3.34 CTITRIGINSTATUS, CTI Trigger In Status register

The CTITRIGINSTATUS characteristics are:

#### Purpose

Provides the status of the trigger inputs.

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

CTITRIGINSTATUS is in the Debug power domain.

#### Attributes

CTITRIGINSTATUS is a 32-bit register.

#### Field descriptions

The CTITRIGINSTATUS bit assignments are:

#### TRIN<n>, bit [n], for n = 0 to 31

Trigger input <n> status.

Bits [31:N] are RAZ. N is the number of CTI triggers implemented as defined by the [CTIDEVID.NUMTRIG](#) field.

Possible values of this bit are:

0 Input trigger n is inactive.

1 Input trigger n is active.

Not implemented and not-connected input triggers are always inactive.

It is IMPLEMENTATION DEFINED whether an input trigger that does not support multicyle events can be observed as active.

#### Accessing the CTITRIGINSTATUS:

CTITRIGINSTATUS can be accessed through the external debug interface:

Component	Offset
CTI	0x130

### H9.3.35 CTITRIGOUTSTATUS, CTI Trigger Out Status register

The CTITRIGOUTSTATUS characteristics are:

#### Purpose

Provides the raw status of the trigger outputs, after processing by any IMPLEMENTATION DEFINED trigger interface logic. For output triggers that are self-acknowledging, this is only meaningful if the CTI implements multicycle channel events.

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

CTITRIGOUTSTATUS is in the Debug power domain.

#### Attributes

CTITRIGOUTSTATUS is a 32-bit register.

#### Field descriptions

The CTITRIGOUTSTATUS bit assignments are:

#### TROUT<n>, bit [n], for n = 0 to 31

Trigger output <n> status.

Bits [31:N] are RAZ, where N is the value of the [CTIDEVID.NUMTRIG](#) field.

If  $n < N$ , and output trigger <n> is implemented and connected, and either the trigger is not self-acknowledging or the CTI implements multicycle channel events, then permitted values for TROUT<n> are:

0 Output trigger n is inactive.

1 Output trigger n is active.

Otherwise when  $n < N$  it is IMPLEMENTATION DEFINED whether TROUT<n> behaves as described here or is RAZ.

#### Accessing the CTITRIGOUTSTATUS:

CTITRIGOUTSTATUS can be accessed through the external debug interface:

Component	Offset
CTI	0x134

# Part I

## **Memory-mapped Components of the ARMv8 Architecture**

# Chapter I1

## System Level Implementation of the Generic Timer

This chapter defines the system level implementation of the Generic Timer. It contains the following sections:

- [About the Generic Timer specification on page I1-5724.](#)
- [Memory-mapped counter module on page I1-5726.](#)
- [Memory-mapped timer components on page I1-5730.](#)
- [Providing a complete set of counter and timer features on page I1-5734.](#)
- [Gray-count scheme for timer distribution scheme on page I1-5736.](#)

---

### Note

- [Generic Timer memory-mapped register descriptions on page I3-5816](#) describes the System level Generic Timer registers. These registers are memory-mapped.
  - [Chapter D6 The Generic Timer in AArch64 state](#) gives a general description of the AArch64 state view of the Generic Timer, and describes the AArch64 System register interface to the Generic Timer.
  - [Chapter G5 The Generic Timer in AArch32 state](#) gives a general description of the AArch32 state view of the Generic Timer, and describes the AArch32 System register interface to the Generic Timer.
-

## I1.1 About the Generic Timer specification

[Chapter D6 The Generic Timer in AArch64 state](#) describes the ARM Generic Timer and its implementation as seen from AArch64 state. [Chapter G5 The Generic Timer in AArch32 state](#) describes the ARM Generic Timer and its implementation as seen from AArch32 state. These chapters include the definition of the low-latency System register interface to the Generic Timer. However, the ARM Generic Timer architecture also defines a memory-mapped component, that comprises:

- A memory-mapped counter module, that controls the generation of the Count value used by the Generic Timer.  
This memory-mapped counter module is required in any ARM Generic Timer implementation that requires software control of the Count value of the Generic Timer.
- Optional memory-mapped timer modules. These give a standardized way of providing timers for programmable system components other than PEs that implement the ARM architecture.

[The full set of Generic Timer components on page D6-2181](#) summarizes these components as seen from AArch64 state, and [The full set of Generic Timer components on page G5-4753](#) summarizes them as seen from AArch32 state. [The system level components of the Generic Timer on page I1-5725](#) summarizes the system level components.

### I1.1.1 Registers in the system level implementation of the Generic Timer

Registers that control components of the system level implementation of the Generic Timer are grouped into *frames*. This specification defines the registers in each frame, and their offsets within the frame. The system defines the position of each frame in the memory map. This means the base addresses for each frame is IMPLEMENTATION DEFINED.

#### ———— Note ————

The final twelve words of the first or only 4KB block of a register memory frame is an ID block.

All memory-mapped peripherals defined in the ARM architecture must be little-endian. This means the system-level Generic Timer registers, and the register frames, are little-endian.

### Power and reset domains for the system level implementation of the Generic Timer

The power and reset domains of the system level implementation of the Generic Timer are IMPLEMENTATION DEFINED as part of the system implementation. These domains can be outside the PE power and reset domains defined by the remainder of this manual.

The ARM architecture requires that the [CNTCR](#).{FCREQ, EN} and [CNTSR](#).FCACK fields reset to 0. These reset values apply only on powerup of the power domain in which the registers are implemented or a reset of the reset domain in which they are implemented.

Every other register, or register field, of a system level implementation of the Generic Timer resets to a value that is architecturally UNKNOWN if it has a meaningful reset value. This applies on powerup of the power domain in which the register is implemented, and on a reset of the reset domain in which it is implemented.

## I1.1.2 The system level components of the Generic Timer

Each system level component has one or two register frames. The possible system level components are:

### The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, [CNTControlBase](#).
- A status frame, [CNTReadBase](#).

*Memory-mapped counter module on page I1-5726* describes this component.

### The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, [CNTCTLBase](#).

*The CNTCTLBase frame on page I1-5731* describes this frame.

### Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the [CNTBaseN](#) frame.
- Optionally provides an unprivileged view of the timer in the [CNTEL0BaseN](#) frame.

*N* is the timer number, and the corresponding frame number, in the range 0-7.

*The CNTBaseN and CNTEL0BaseN frames on page I1-5732* describes these frames.

## I1.2 Memory-mapped counter module

The memory-mapped counter module provides top-level control of the system counter. The [CNTControlBase](#) frame holds the registers for the memory-mapped counter, and provides:

- A RW control register [CNTCR](#), that provides:
  - An enable bit for the system counter.
  - An enable bit for Halt-on-Debug. When this is enabled, if the debug halt signal into the system counter is asserted, it halts the system counter. Otherwise, the system counter ignores the state of this halt signal. For more information about Halt-on-Debug, contact ARM.
  - A field that can be written to request a change to the update frequency of the system counter, with a corresponding change to the increment made at each update. This mechanism means that, for example, if the update frequency is halved, the increment at each update is doubled.

For more information see [Control of counter operating frequency and increment on page I1-5727](#).

Writes to this register are rare. In a system that supports two Security states, this register is writable only by Secure writes.

- A RO status register, [CNTSR](#), that provides:
  - A bit that indicates whether the system counter is halted because of an asserted Halt-on-Debug signal.
  - A field that indicates the current update frequency of the system counter. This field can be polled to determine when a requested change to the update frequency has been made.

- Two contiguous 32-bit RW registers that hold the current system counter value, [CNTCV](#). If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

The system counter must be disabled before writing to these registers, otherwise the effect of the write is UNPREDICTABLE.

Writes to these registers are rare. In a system that supports two Security states, these registers are writable only by Secure writes.

- A *Frequency modes table* of one or more 32-bit entries, where:
  - The first entry in the table defines the *base frequency* of the system counter. This is the maximum frequency at which the counter updates.
  - Each subsequent entry in the table defines an alternative frequency of the system counter, that must be an exact divisor of the base frequency.

A 32-bit zero entry immediately follows the last table entry.

This table can be RO or RW. For more information, see [The Frequency modes table on page I1-5727](#).

In addition, the [CNTReadBase](#) frame includes a read-only copy of the system counter value, [CNTCV](#), as two contiguous 32-bit RO registers. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

[Counter module control and status register summary on page I1-5728](#) describes [CNTReadBase](#) and [CNTControlBase](#) memory maps, and the registers in each frame.

## I1.2.1 Control of counter operating frequency and increment

The system counter has a fixed *base frequency*, and must maintain the required counter accuracy, meaning ARM recommends that it does not gain or lose more than ten seconds in a 24-hour period, see [The system counter on page D6-2182](#). However, the counter can increment at a lower frequency than the base frequency, using a correspondingly larger increment. For example, it can increment by four at a quarter of the base frequency. Any lower-frequency operation, and any switching between operating frequencies, must not reduce the accuracy of the counter.

Control of the system counter frequency and increment is provided only through the memory-mapped counter module. The following sections describe this control:

- [The Frequency modes table](#).
- [Changing the system counter and increment](#).

### The Frequency modes table

The Frequency modes table starts at offset 0x20 in the [CNTControlBase](#) frame.

Table entries are 32-bits, and each entry specifies a system counter update frequency, in Hz.

The first entry in the table specifies the base frequency of the system counter.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

$$\text{increment} = (\text{base\_frequency}) / (\text{selected\_frequency})$$

A 32-bit word of zero value marks the end of the table. That is, the word of memory immediately after the last entry in the table must be zero.

The only required entry in the table is the entry for the base frequency.

Typically, the Frequency modes table is in RO memory. However, a system implementation might use RW memory for the table, and initialize the table entries as part of its startup sequence. Therefore, the [CNTControlBase](#) memory map shows the table region as RO or RW.

ARM strongly recommends that the Frequency modes table is not updated once the system is running.

The architecture can support up to 1004 entries in the Frequency modes table, including the zero-word end marker, and the maximum number of entries is IMPLEMENTATION DEFINED, up to this limit.

#### ————— Note —————

- ARM considers it likely that implementations will require significantly fewer entries than the architectural limit.
- In the [CNTControlBase](#) frame, the offset range 0x0C0-0x0FC can be used for IMPLEMENTATION DEFINED registers. If any registers are defined in this space then the Frequency modes table cannot extend beyond offset 0x0B8, with a zero word at offset 0x0BC. This means the maximum number of entries in the table is 40, including the zero-word end marker.

### Changing the system counter and increment

The value of the [CNTCR.FCREQ](#) field specifies which entry in the Frequency modes table specifies the system counter update frequency.

Changing the value of [CNTCR.FCREQ](#) requests a change to the system counter update frequency. To ensure the frequency change does not affect the overall accuracy of the counter, a change is made as follows:

- When changing from a higher frequency to a lower frequency, the counter:
  1. Continues running at the higher frequency until the count reaches an integer multiple of the required lower frequency.
  2. Switches to operating at the lower frequency.

- When changing from a lower frequency to a higher frequency, the counter:
  1. Waits until the end of the current lower-frequency cycle.
  2. Makes the counter increment required for operation at that lower frequency.
  3. Switches to operating at the higher frequency.

When the frequency has changed, [CNTSR](#) is updated to indicate the new frequency. Therefore, a system component that is waiting for a frequency change can poll [CNTSR](#) to detect the change.

## I1.2.2 Counter module control and status register summary

The Counter module control and status registers are memory-mapped registers in the following register memory frames:

- A control frame, with base address [CNTControlBase](#).
- A status frame, with base address [CNTReadBase](#).

Each of these register memory frames is at least 4KB in size, or is at least the size of the memory protection granule if this granule size is larger than 4KB. Similarly, each base address must be aligned to 4KB, or to the memory protection granule if that is larger than 4KB.

### ———— Note ————

- The memory protection granule is either 4KB, 16KB or 64KB.
- Each frame of a memory-mapped Generic Timer takes the name of its base address.

In each register memory frame, the memory at offset 0xFD0-0xFFF is reserved for twelve 32-bit IMPLEMENTATION DEFINED ID registers, see the [CounterID<n>](#) register descriptions for more information.

### ———— Note ————

The ARM architecture requires memory-mapped peripherals to be little-endian, and therefore the counter is little-endian.

In an implementation that supports Secure and Non-secure memory maps, [CNTControlBase](#) is implemented only in the Secure memory map.

[Table I1-1](#) shows the [CNTControlBase](#) control registers, in order of their offsets from the [CNTControlBase](#) base address, for an implementation that includes registers in the implementation defined register space 0x0C0-0x0FC, and also has fewer than 39 [CNTFID<n>](#) registers. [The Frequency modes table on page I1-5727](#) describes how this memory map differs if more [CNTFID<n>](#) registers are implemented.

[Generic Timer memory-mapped register descriptions on page I3-5816](#) describes each of these registers.

**Table I1-1 CNTControlBase memory map**

Offset	Name	Type	Description
0x000	<a href="#">CNTCR</a>	RW	Counter Control Register.
0x004	<a href="#">CNTSR</a>	RO	Counter Status Register.

0x008-0xFCC	-	RES0	Reserved
0xFD0-0xFFC	<a href="#">CounterID&lt;n&gt;</a>	RO	Counter ID registers 0-11

## I1.3 Memory-mapped timer components

This part of the ARM Generic Timer specification defines an optional memory-mapped timer component. This can be implemented as part of any programmable system component that does not incorporate a System register mapped ARM Generic Timer, to provide that system component with the timer functionality of an ARM Generic Timer.

The memory map consists of up to 8 timer *frames*. Each timer frame:

- Provides its own set of timers and associated interrupts.
- Is in its own memory protection region that is:
  - In its own memory protection region, with a system-defined size of 4KB, 16KB or 64KB.
  - At a start address that is aligned to 4KB.

**Note**

The start address 4KB alignment requirement applies regardless of the memory protection region size.

The base address of a frame is `CNTBaseN`, where *N* numbers from 0 up to a maximum permitted value of 7.

For each implemented `CNTBaseN` frame the system can optionally provide an unprivileged view of the frame, described as the EL0 view of the frame. The base address of this second view of the `CNTBaseN` frame is `CNTELOBaseN`.

**Note**

In the naming of the registers associated with a `CNTBaseN` or `CNTELOBaseN` frame, the value of *N* is represented as `<n>`, for example `CNTACR<n>`.

If a `CNTELOBaseN` frame is implemented:

- All registers visible in `CNTBaseN` can be visible, except for `CNTVOFF` and `CNTELOACR`.
  - Control fields in `CNTELOACR` determine whether the registers are visible.
- The offsets of all visible registers are the same as their offsets in the `CNTBaseN` frame.

In addition to the implemented `CNTBaseN` and `CNTELOBaseN` frames, the system must provide a single control frame at base address `CNTCTLBase`.

The memory protection region and alignment requirements for the `CNTELOBaseN` and `CNTCTLBase` frames are the same as the requirements for the `CNTBaseN` frames.

The system defines the position of each frame in the memory map. This means the values of each of the `CNTBaseN`, `CNTELOBaseN`, and `CNTCTLBase` base addresses is IMPLEMENTATION DEFINED.

**Note**

The ARM architecture requires memory-mapped peripherals to be little-endian, and therefore the memory-mapped timers are little-endian.

The following sections describe the implementation of a memory-mapped view of the counter and timer:

- [The `CNTCTLBase` frame on page I1-5731.](#)
- [The `CNTBaseN` and `CNTELOBaseN` frames on page I1-5732.](#)
- [Providing a complete set of counter and timer features on page I1-5734.](#)

### I1.3.1 The CNTCTLBase frame

The [CNTCTLBase](#) frame contains:

- An identification register for the features of the memory-mapped counter and timer implementation.
- Access controls for each [CNTBaseN](#) frame.
- A virtual offset register for frames that implement a virtual timer.

[Table I1-3](#) shows the [CNTCTLBase](#) registers, in order of their offsets from the [CNTCTLBase](#) base address.

———— **Note** ————

[CNTFRQ](#) and [CNTVOFF](#) registers are also implemented in a System register interface to the Generic Timer.

*Generic Timer memory-mapped register descriptions on page I3-5816* describes each of these registers.

**Table I1-3 CNTCTLBase memory map**

Offset	Register	Type	Security <sup>a</sup>	Description
0x000	<a href="#">CNTFRQ</a> <sup>b</sup>	RW	Secure	Counter Frequency register.
0x004	<a href="#">CNTNSAR</a>	RW	Secure	Counter Non-Secure Access register.
0x008	<a href="#">CNTTIDR</a>	RO	Both	Counter Timer ID register.
0x00C- 0x03F	-	RES0	-	Reserved.
0x040+4N <sup>c</sup>	<a href="#">CNTACR</a> <n>	RW	Configurable <sup>d</sup>	Counter Access Control register N.
0x060- 0x07F	-	RES0	-	Reserved.
0x080+8N <sup>c</sup>	<a href="#">CNTVOFF</a> <n>[31:0] <sup>b</sup>	RW <sup>e</sup>	Configurable <sup>d</sup>	Virtual Offset register N. If the <a href="#">CNTBaseN</a> frame has virtual timer capability then <a href="#">CNTVOFF</a> is implemented as a RW register, otherwise its location is RAZ/WI.
0x084+8N <sup>c</sup>	<a href="#">CNTVOFF</a> <n>[63:32] <sup>b</sup>	RW <sup>e</sup>		
0x0C0-0x0FC	-	RES0	-	Reserved.
0x100-0x7FC	-	-	-	IMPLEMENTATION DEFINED.
0x800-0xFBC	-	RES0	-	Reserved.
0xFC0-0xFCF	-	-	-	IMPLEMENTATION DEFINED.
0xFD0- 0xFFC	<a href="#">CounterID</a> <n>	RO	Both	Counter ID registers 0-11.

- Access security requirement in an implementation that supports two Security states. In an implementation that does not support multiple Security states all registers are accessible as shown in the *Type* column.
- These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers on page D7-2672* and *Generic Timer registers on page G6-5383*. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.
- Implemented for each value of N from 0 to 7 for which a [CNTBaseN](#) frame is implemented.
- The [CNTNSAR](#) determines the Non-secure accessibility of the [CNTACR](#)<n>s and the [CNTVOFF](#)<n>s in the [CNTCTLBase](#) frame. For more information, see the register descriptions.
- Address is reserved, RAZ/WI if register not implemented.

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the [CNTVOFF](#) register that defines the virtual offset between the physical count and the virtual count. If a memory-mapped Generic Timer component does not distinguish between real time and virtual time then it can implement [CNTVOFF](#) as RAZ/WI. Otherwise [CNTVOFF](#) is a RW register, and ARM strongly recommends that the system only permits access to [CNTVOFF](#) from EL2 or higher.

### 11.3.2 The CNTBaseN and CNTEL0BaseN frames

Each [CNTBaseN](#) frame, or {[CNTBaseN](#), [CNTEL0BaseN](#)} pair of frames, provides a memory-mapped counter and timer, see:

- [The CNTBaseN frame.](#)
- [The CNTEL0BaseN frame on page I1-5733.](#)
- [CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733.](#)

#### The CNTBaseN frame

[Table I1-4](#) shows the [CNTBaseN](#) registers, in order of their offsets from the [CNTBaseN](#) base address. Whether a frame includes a virtual timer is IMPLEMENTATION DEFINED. If it does not then memory at offsets 0x030-0x03C is RAZ/WI. Except for [CNTEL0ACR](#) and the [CounterID<n>](#) registers, equivalent registers are also implemented in a System register interface to the timer component of a Generic Timer.

[Generic Timer memory-mapped register descriptions on page I3-5816](#) describes each of these registers.

**Table I1-4 CNTBaseN memory map**

Offset	Register	Type	Description
0x000	<a href="#">CNTPCT</a> [31:0] <sup>a</sup>	RO	Physical Count register.
0x004	<a href="#">CNTPCT</a> [63:32] <sup>a</sup>	RO	
0x008	<a href="#">CNTVCT</a> [31:0] <sup>a</sup>	RO	Virtual Count register.
0x00C	<a href="#">CNTVCT</a> [63:32] <sup>a</sup>	RO	
0x010	<a href="#">CNTFRQ</a> <sup>a</sup>	RO <sup>c</sup>	Counter Frequency register.
0x014	<a href="#">CNTEL0ACR</a>	RW <sup>b</sup>	Counter EL0 Access Control Register, optional in the <a href="#">CNTBaseN</a> memory map.
0x018	<a href="#">CNTVOFF</a> [31:0] <sup>a</sup>	RO <sup>c</sup>	Virtual Offset register. If <a href="#">CNTVOFF&lt;n&gt;</a> in the <a href="#">CNTCTLBase</a> frame is a RW register, a read of this register returns the value of that register. Otherwise is RAZ.
0x01C	<a href="#">CNTVOFF</a> [63:32] <sup>a</sup>	RO <sup>c</sup>	
0x020	<a href="#">CNTP_CVAL</a> [31:0] <sup>a</sup>	RW	Physical Timer CompareValue register.
0x024	<a href="#">CNTP_CVAL</a> [63:32] <sup>a</sup>	RW	
0x028	<a href="#">CNTP_TVAL</a> <sup>a</sup>	RW	Physical TimerValue register.
0x02C	<a href="#">CNTP_CTL</a> <sup>a</sup>	RW	Physical Timer Control register.
0x030	<a href="#">CNTV_CVAL</a> [31:0] <sup>a</sup>	RW <sup>b</sup>	Virtual Timer CompareValue register, optional in the <a href="#">CNTBaseN</a> memory map.
0x034	<a href="#">CNTV_CVAL</a> [63:32] <sup>a</sup>	RW <sup>b</sup>	
0x038	<a href="#">CNTV_TVAL</a> <sup>a</sup>	RW <sup>b</sup>	Virtual TimerValue register, optional in the <a href="#">CNTBaseN</a> memory map.
0x03C	<a href="#">CNTV_CTL</a> <sup>a</sup>	RW <sup>b</sup>	Virtual Timer Control register, optional in the <a href="#">CNTBaseN</a> memory map.
0x040-0xFCF	-	RES0	Reserved.
0xFD0-0xFFC	<a href="#">CounterID&lt;n&gt;</a>	RO	Counter ID registers 0-11.

a. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in [Generic Timer registers on page D7-2672](#) and [Generic Timer registers on page G6-5383](#). The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

b. Address is reserved, RAZ/WI if register not implemented

c. The [CNTCTLBase](#) frame includes a RW view of this register.

## The CNTEL0BaseN frame

For any value of  $N$ , the layout of the registers in the CNTEL0BaseN frame is identical to the CNTBaseN frame, except that, in the CNTEL0BaseN frame:

- CNTVOFF is never visible, and the memory at 0x018-0x01C is RAZ/WI.
- CNTEL0ACR is never visible, and the memory at 0x014 is RAZ/WI.
- If implemented in the CNTBaseN frame, CNTEL0ACR controls whether CNTPCT, CNTVCT, CNTFRQ, the Physical Timer, and the Virtual Timer registers are visible in the CNTEL0BaseN frame.  
If CNTEL0ACR is not implemented then these registers are not visible in the CNTEL0BaseN frame, and their addresses in that frame are RAZ/WI.

If an implementation supports 64-bit atomic accesses, then CNTPCT, CNTVCT, CNTVOFF, CNTP\_CVAL, and CNTV\_CVAL must be accessible as atomic 64-bit values.

## CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames

In the CNTCTLBase frame:

### CNTTIDR controls:

- Whether each CNTBaseN frame is implemented.
- If a CNTBaseN frame is implemented, whether:
  - That CNTBaseN frame has virtual timer capability.
  - A corresponding CNTEL0BaseN frame is implemented.

### CNTNSAR controls:

In an implementation that recognizes two Security states, determines whether each implemented CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

This control also determines whether, in the CNTCTLBase frame, the CNTACR<n> and CNTVOFF<n> registers are accessible by Non-secure accesses.

### The CNTACR<n> registers control:

For each implemented CNTBaseN frame, the accessibility of the following registers in that frame:

- CNTP\_CTL, CNTP\_CVAL, and CNTP\_TVAL.
- CNTV\_CTL, CNTV\_CVAL, and CNTV\_TVAL.
- CNTVOFF.
- CNTFRQ.
- CNTPCT.
- CNTVCT.

For CNTACR<n>, the value of <n> corresponds to the value of  $N$  for the controlled CNTBaseN frame.

### The CNTVOFF<n> registers provide:

For each implemented CNTBaseN frame that has virtual capability, the RW copy of the CNTVOFF register for that frame.

#### ————— Note —————

In a CNTBaseN frame that has virtual timer capability the CNTVOFF register is RO.

For CNTVOFF<n>, the value of <n> corresponds to the value of  $N$  for the controlled CNTBaseN frame.

## I1.4 Providing a complete set of counter and timer features

Using the general model for implementing a memory-mapped interface to the Generic Timer described in this section, the feature set of a System registers counter and timer, in an implementation that includes EL2 and EL3, can be implemented using the following set of timer frames:

- A **CNTCTLBase** control frame.
- The following **CNTBaseN** timer frames:
  - Frame 0** Accessible from Non-secure state, with second view and virtual capability. This provides the Non-secure EL1&0 timers.
  - Frame 1** Accessible from Non-secure state, with no second view and no virtual capability. This provides the Non-secure EL2 timers.
  - Frame 2** Accessible only from Secure state, with a second view but no virtual capability. This provides the Secure PL1&0 timers, meaning:
    - Compared to a PE where EL3 is using AArch32, it provides the only Secure state timer.
    - Compared to a PE where EL3 is using AArch64, it provides the Secure EL1&0 timer.
  - Frame 3** Accessible only Secure state, with no second view and no virtual capability. This provides the Secure EL3 timers.

### Note

This frame is not required for a memory-mapped timer that provides only the feature set of a PE for which EL3 is using AArch32.

In this implementation, the full set of implemented frames, and their configuration in the memory map, is as follows:

#### CNTCTLBase

The control frame. This frame is located in both Secure and Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

#### CNTBase0

The first view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

#### CNTEL0Base0

The second view of **CNTBase0**, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, the architecture permits this frame to be accessible at EL1, or at EL1 and EL0, but does not require either of these options.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.

#### CNTBase1

The first and only view of the Non-secure EL2 timers. This frame is located only in Non-secure physical memory, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

**CNTBase2** The first view of the Secure EL1&0, or PL1&0 timers.

---

**Note**

---

In AArch64 state, these timers are always called the Secure EL1&0 timers. In AArch32 state they are usually called the Secure PL1&0 timers because, in AArch32 Secure state, whether some of the PE modes map to EL1 or to EL3 depends on whether EL3 is using AArch64 or is using AArch32, see [Security state, Exception levels, and AArch32 execution privilege](#) on page G1-4318.

---

This frame is located only in Secure physical memory, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

**CNTEL0Base2**

The second view of [CNTBase2](#), meaning it is the EL0 view of the Secure EL1&0, or PL1&0, timers.

---

**Note**

---

See the Note in the description of the CNTBase2 frame for more information about the naming of these timers.

---

This frame is located only in Secure physical memory, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible at PL1 (EL3) and EL0.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

**CNTBase3** The first and only view of the EL3 timers. This frame is located only in Secure physical memory, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is not accessible.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, this frame is not accessible.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

---

**Note**

---

[About the Virtual Memory System Architecture \(VMSA\)](#) on page D4-2004 describes the VMSAv8-64 translation regimes, and [About VMSAv8-32](#) on page G4-4558 describes the VMSAv8-32 translation regimes.

---

## I1.5 Gray-count scheme for timer distribution scheme

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

$$\text{Gray}[N] = \text{Count}[N]$$

$$\text{Gray}[i] = (\text{XOR}(\text{Gray}[N:i+1])) \text{ XOR } \text{Count}[i] \text{ for } N-1 \geq i \geq 0$$

$$\text{Count}[i] = \text{XOR}(\text{Gray}[N:i]) \text{ for } N \geq i \geq 0$$

This is for an  $N+1$  bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

### ———— **Note** ————

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be  $2^n$ , where  $n$  is an integer. A switch-over can occur only on the  $2n+1$  boundary to avoid losing the Gray-coding property on a switch-over.

# Chapter I2

## Recommended External Interface to the Performance Monitors

This chapter describes the recommended external interface to the Performance Monitors. It contains the following section:

- [About the external interface to the Performance Monitors registers on page I2-5738.](#)

———— **Note** —————

[Performance Monitors external register descriptions on page I3-5749](#) describes the external view of the Performance Monitors registers.

—————

## I2.1 About the external interface to the Performance Monitors registers

ARM recommends that:

- An implementation provides the OPTIONAL external debug interface to the Performance Monitors registers.

———— **Note** ————

A debugger can use this interface to access counters in the Performance Monitors.

- The implementation includes the OPTIONAL support for memory-mapped access to the External debug interface.

———— **Note** ————

— Software running on any PE in a system can use this interface to access counters in the Performance Monitors.

— Privileged software should use the MMU to control access to this interface.

- The external debug interface is implemented as defined in [Appendix K2 Recommended External Debug Interface](#).

When an implementation supports memory-mapped access to the external debug interface the interface is accessed as a little-endian memory-mapped peripheral. [External Performance Monitors registers summary on page I3-5746](#) gives the memory map of these registers.

The following sections describe the memory-mapped views of the Performance Monitors registers:

- [Differences in the external views of the Performance Monitors registers](#).
- [Synchronization of changes to the memory-mapped views on page I2-5739](#).
- [Access permissions for external views of the Performance Monitors on page I2-5739](#).

In this section, unless the context explicitly indicates otherwise, any reference to *a memory-mapped view* applies equally to a register view using:

- A access through an external debug interface.
- A memory-mapped access.

### I2.1.1 Differences in the external views of the Performance Monitors registers

An external view of the Performance Monitors registers accesses the same registers as the System registers interface described in [Performance Monitors Extension registers on page D5-2176](#), except that:

1. The [PMSELR](#) is accessible only in the System registers interface.
2. The following registers are accessible only in external views:
  - [PMCFGR](#)
  - [PMDEVAFF0](#)
  - [PMDEVAFF1](#)
  - [PMLAR](#)
  - [PMLSR](#)
  - [PMAUTHSTATUS](#)
  - [PMDEVARCH](#)
  - [PMDEVTYPE](#)
  - [PMPIDR0](#)
  - [PMPIDR1](#)
  - [PMPIDR2](#)
  - [PMPIDR3](#)

- [PMPIDR4](#)
- [PMCIDR0](#)
- [PMCIDR1](#)
- [PMCIDR2](#)
- [PMCIDR3](#)

*Performance Monitors external register descriptions on page I3-5749* describes these registers.

3. The following controls do not affect the external views:
  - [PMSELR](#).
  - [PMUSERENR](#).
  - [HDCR](#).{TPM, TPMCR, HPMN}.

Instead, see the register descriptions in [Chapter I3 External System Control Register Descriptions](#).

## I2.1.2 Synchronization of changes to the memory-mapped views

If a Performance Monitor is visible in both System register and an external view, and is accessed simultaneously through these two mechanisms, the behavior must be as if the access occurred atomically in any order. For more information, see [Synchronization of changes to the external debug registers on page H8-5554](#).

## I2.1.3 Access permissions for external views of the Performance Monitors

For more information, see [External debug interface register access permissions on page H8-5561](#).

[Table I2-1 on page I2-5740](#) shows the access permissions for the Performance Monitors registers in a v8 Debug implementation. This table uses the following terms:

<b>DLK</b>	When the OS Double Lock is locked, <a href="#">DoubleLockStatus()</a> == TRUE, accesses to some registers produce an error. Applies to both interfaces.
<b>EPMAD</b>	When <a href="#">AllowExternalPMUAccess()</a> == FALSE, external debug access is disabled. See also <a href="#">Behavior of a not permitted memory-mapped access on page H8-5559</a> .
<b>Error</b>	Indicates that the access gives an error response.
<b>Default</b>	This shows the default access permissions, if none of the conditions in this list prevent access to the register.
<b>Off</b>	When <a href="#">EDPRSR.PU</a> == 0, the Core power domain is completely off, or in a low-power state where the Core power domain registers cannot be accessed.

### ————— **Note** —————

If debug power is off, then all external debug interface accesses return an error.

<b>OSLK</b>	When the OS Lock is locked, <a href="#">OSLAR_EL1.OSLK</a> == 1, accesses to some registers produces an error. This column shows the effect of this control on accesses using the external debug interface.
<b>SLK</b>	This indicates the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See <a href="#">Register access permissions for memory-mapped accesses on page H8-5558</a> . For all other accesses, this column is ignored.
<b>-</b>	Indicates that the control has no effect on the behavior of the access: <ul style="list-style-type: none"> <li>• If no other control affects the behavior, the Default access behavior applies.</li> </ul>

- However, another control might determine the behavior.

**Table I2-1 Access permissions for the Performance Monitors registers**

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	Default	SLK
0x000+8xn	PMEVCNTR<n>_EL0 <sup>a</sup>	Core	Error	Error	Error	Error	RW	RO

0xE80-0xEFC	Integration registers	-	Access is IMPLEMENTATION DEFINED					
0xF00-0xFFC	Management registers and CoreSight compliance on page K2-6141							

a. Implemented counters only. *n* is the counter number.

- b. Implemented only if the [OPTIONAL PC Sample-based Profiling Extension](#) is implemented and ARMv8.2-PCSample is implemented. See [Chapter H7 The PC Sample-based Profiling Extension](#).
- c. Only if the `OPTIONAL PMSWINC_EL0` register is implemented in the external debug interface.

#### I2.1.4 Power domains and Performance Monitors registers reset

For ARMv8-A implementations, ARM recommends that Performance Monitors are implemented as part of the core power domain, not as part of a separate debug power domain. There is no interface to access the Performance Monitors registers when the core power domain is powered down.

A Warm or Cold reset sets the Performance Monitors registers to their reset values. An External Debug reset does not change the values of the Performance Monitors registers.

For more information about the reset scheme recommended for a v8 Debug implementation see [Chapter H6 Debug Reset and Powerdown Support](#).

[Table I2-2](#) shows the Performance Monitors register resets for writable register fields. The column headings use the following terms:

- 64** This is the architectural reset value when resetting into AArch64 state.
- 32** This is the architectural reset value when resetting into AArch32 state.
- This indicates an IMPLEMENTATION DEFINED reset value on the specified reset. This might be UNKNOWN.

#### ———— Note —————

This table does not include:

- Read-only identification registers and fields that have a fixed value. In this case, the reset value is that fixed value. An example of this is [PMCR\\_EL0.N](#).
- Write-only registers and fields that only have an effect on writes. These do not have a reset value. An example of this is [PMSWINC\\_EL0](#).
- IMPLEMENTATION DEFINED registers. In this case, the reset domains are IMPLEMENTATION DEFINED. The reset values are IMPLEMENTATION DEFINED and might be UNKNOWN.

**Table I2-2 Performance Monitors System register resets**

Register	Domain	Field	64	32	Description
<a href="#">PMCR_EL0</a>	Warm	DP	-	0	Disable PMCCNTR_EL0 when prohibited
		X	-	0	Export enable
		D	-	0	Clock divider
		E	0	0	Performance Monitors enable

# Chapter I3

## External System Control Register Descriptions

This chapter describes the external system control registers and supported access sizes. It excludes the External debug registers that are described in [Chapter H9 External Debug Register Descriptions](#). It contains the following sections:

- [About the external system control register descriptions on page I3-5744.](#)
- [Supported access sizes on page I3-5745.](#)
- [External Performance Monitors registers summary on page I3-5746.](#)
- [Performance Monitors external register descriptions on page I3-5749.](#)
- [Generic Timer memory-mapped registers overview on page I3-5815.](#)
- [Generic Timer memory-mapped register descriptions on page I3-5816.](#)

## I3.1 About the external system control register descriptions

This chapter describes the external system control registers other than the external debug registers. That is, it describes:

### An external view of the Performance Monitors registers

ARM recommends that implementations provide access to the Performance Monitors registers through the OPTIONAL External debug interface, and provide the OPTIONAL memory-mapped interface to this interface:

- [External Performance Monitors registers summary on page I3-5746](#) lists the registers that are accessible in this view of the Performance Monitors, and describes their memory map.
- [Performance Monitors external register descriptions on page I3-5749](#) describes each of the memory-mapped registers.

[Chapter I2 Recommended External Interface to the Performance Monitors](#) describes the recommended interface to these registers.

---

#### Note

[Chapter D5 The Performance Monitors Extension](#) describes the Performance Monitors. The following sections describe the System register interfaces to the Performance Monitors:

- [Performance Monitors registers on page D7-2629](#), for accesses from an Exception level that is using AArch64.
  - [Performance Monitors registers on page G6-5331](#), for accesses from an Exception level that is using AArch32.
- 

### The registers for the system level Generic Timer component

Any implementation that includes the Generic Timer must include the memory-mapped system level component described in [Chapter I1 System Level Implementation of the Generic Timer](#). In this chapter:

- [Generic Timer memory-mapped registers overview on page I3-5815](#) gives an overview of the registers, referring to [Chapter I1](#) for more information.
- [Generic Timer memory-mapped register descriptions on page I3-5816](#) describes each of the memory-mapped registers.

---

#### Note

[Chapter D6 The Generic Timer in AArch64 state](#) describes the Generic Timer component that is accessible using the System registers. The following sections describe the System register interfaces to that component:

- [Generic Timer registers on page D7-2672](#), for accesses from an Exception level that is using AArch64.
  - [Generic Timer registers on page G6-5383](#), for accesses from an Exception level that is using AArch32.
- 

---

#### Note

[Chapter H9 External Debug Register Descriptions](#) describes the external debug registers.

---

## I3.2 Supported access sizes

All of the information that is provided in this section applies to all accesses to memory-mapped components of the ARMv8 architecture, unless a register or component description explicitly states otherwise.

The memory access sizes that are supported by any peripheral are IMPLEMENTATION DEFINED by the peripheral.

For accesses to memory-mapped components of the ARMv8 architecture, implementations must support the following options:

- Word-aligned 32-bit accesses to access 32-bit registers.
- Word-aligned 32-bit accesses to either half of a 64-bit register that is mapped to a doubleword-aligned pair of adjacent 32-bit locations,
- Doubleword-aligned 64-bit accesses to access 64-bit registers that are mapped to a doubleword-aligned pair of adjacent 32-bit locations.

All registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- Byte accesses.
- Halfword accesses.
- Unaligned word accesses. These accesses are not word single-copy atomic.
- Unaligned doubleword accesses. These accesses are not doubleword single-copy atomic.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair that forms a 64-bit register.
- Quadword accesses or higher accesses.
- Exclusive accesses.

For unsupported accesses, it is CONSTRAINED UNPREDICTABLE whether:

- The access generates an external abort or not.
- The defined side-effects of a read occur or not. A read returns UNKNOWN values.
- A write is ignored or sets the accessed register or registers to UNKNOWN.

For memory-mapped accesses from a PE that complies with an ARM architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory that is accessed, determine the size of the access that is made by an instruction. [Example I3-1](#) shows this.

### Example I3-1 Access sizes for memory-mapped accesses

Two Load Doubleword instructions that are made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

The ARMv8 architecture does not require the size of each element that is accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Unless otherwise specified by the component, any access to a memory-mapped component of the ARMv8 architecture is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory type, and only single register load and store instructions, to create memory accesses that are supported by the peripheral. For more information, see [Memory types and attributes on page B2-107](#).

## I3.3 External Performance Monitors registers summary

When an implementation provides access to the Performance Monitors registers through the External debug interface, that interface provides access to:

- Performance Monitors System registers.
- A read-only configuration register, [PMCFGR](#).
- The OPTIONAL CoreSight registers for the Performance Monitors, if they are implemented.

The locations of the registers are defined as offsets from a system-defined base address. [Performance Monitors external register views](#) defines this memory map.

### I3.3.1 Performance Monitors external register views

[Table I3-1](#) shows the external view of the Performance Monitors registers. All other entries are reserved.

#### Note

- Counters that are reserved because [HDCR.HPMN](#) has been changed from its reset value remain visible in any external view.
- The registers that relate to an implemented event counter, PMN<sub>x</sub>, are [PMEVCNTR<n>](#) and [PMEVTYPER<n>](#).
- The mapping of the *Performance Monitors Event Counter Registers*, at offsets 0x000-0x0F4, has changed compared to the mappings of the equivalent registers in ARMv7.

Each entry in the Name column links to the register description in [Performance Monitors external register descriptions](#) on page I3-5749, and:

- If the *System register?* column of the table shows that the register is a System register, the memory-mapped interface provides a view of the System register described in:
  - [Performance Monitors registers](#) on page D7-2629, for the AArch64 System register
  - [Performance Monitors registers](#) on page G6-5331, for the AArch32 System register
- Otherwise, the register is accessible only using the external interface.

**Table I3-1 Performance Monitors external register views**

<a href="#">PMPIDR2<sup>c</sup></a>	RO			0xFE8
<a href="#">PMPIDR3<sup>c</sup></a>	RO			0xFEC

**Table I3-1 Performance Monitors external register views (continued)**

Name	Type	Description	System register?	Offset
<a href="#">PMCIDR0<sup>c</sup></a>	RO	Component ID registers	No	0xFF0
<a href="#">PMCIDR1<sup>c</sup></a>	RO			0xFF4
<a href="#">PMCIDR2<sup>c</sup></a>	RO			0xFF8
<a href="#">PMCIDR3<sup>c</sup></a>	RO			0xFFC

- The interface must support at least single-copy atomic 32-bit accesses. If single-copy atomic 64-bit access to the registers is not possible, software must use a high-low-high read access to read the counter value if the counter is enabled.
- Supported from ARMv8.2. Until ARMv8.1, the functionality of PC Sample-Based Profiling is implemented with registers in the EDxxx space. See Chapter H7 *The PC Sample-based Profiling Extension*.  
Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented.
- CoreSight interface registers, see [Management registers and CoreSight compliance on page K2-6141](#).
- The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

## I3.4 Performance Monitors external register descriptions

This section describes the external view of the Performance Monitors registers. [External Performance Monitors registers summary on page I3-5746](#) lists these registers in offset order.

### I3.4.1 PMAUTHSTATUS, Performance Monitors Authentication Status register

The PMAUTHSTATUS characteristics are:

#### Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

PMAUTHSTATUS is in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance. ARM recommends that this register is implemented.

#### Attributes

PMAUTHSTATUS is a 32-bit register.

#### Field descriptions

The PMAUTHSTATUS bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### SNID, bits [7:6]

Holds the same value as [DBGAUTHSTATUS\\_EL1.SNID](#).

#### SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

00 Not implemented.

All other values are reserved.

#### NSNID, bits [3:2]

Holds the same value as [DBGAUTHSTATUS\\_EL1.NSNID](#).

#### NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

00 Not implemented.

All other values are reserved.

### Accessing the PMAUTHSTATUS:

PMAUTHSTATUS can be accessed through the external debug interface:

Component	Offset
PMU	0xFB8

### 13.4.2 PMCCFILTR\_EL0, Performance Monitors Cycle Counter Filter Register

The PMCCFILTR\_EL0 characteristics are:

**Purpose**

Determines the modes in which the Cycle Counter, [PMCCNTR\\_EL0](#), increments.

**Usage constraints**

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

**Configurations**

External register PMCCFILTR\_EL0 is architecturally mapped to AArch64 System register [PMCCFILTR\\_EL0](#).

External register PMCCFILTR\_EL0 is architecturally mapped to AArch32 System register [PMCCFILTR](#).

PMCCFILTR\_EL0 is in the Core power domain.

On a Warm or Cold reset RW fields in this register reset:

- To architecturally UNKNOWN values if the reset is to an Exception level that is using AArch64.
- To 0 if the reset is to an Exception level that is using AArch32.

The register is not affected by an External debug reset.

**Attributes**

PMCCFILTR\_EL0 is a 32-bit register.

**Field descriptions**

The PMCCFILTR\_EL0 bit assignments are:

**P, bit [31]**

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count cycles in EL1.
- 1 Do not count cycles in EL1.

**U, bit [30]**

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count cycles in EL0.

1 Do not count cycles in EL0.

#### NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

#### NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

#### NSH, bit [27]

Non-secure EL2 (Hypervisor) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count cycles in EL2.

1 Count cycles in EL2.

#### M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to 0.

#### ————— **Note** —————

This field is not visible in the AArch32 PMCCFILTR System register.

#### Bits [25:0]

Reserved, RES0.

#### Accessing the PMCCFILTR\_EL0:

PMCCFILTR\_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0x47C

### I3.4.3 PMCCNTR\_EL0, Performance Monitors Cycle Counter

The PMCCNTR\_EL0 characteristics are:

**Purpose**

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See [Time as measured by the Performance Monitors cycle counter on page D5-2139](#) for more information.

[PMCCFILTR\\_EL0](#) determines the modes and states in which the PMCCNTR\_EL0 can increment.

**Usage constraints**

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

**Configurations**

External register PMCCNTR\_EL0 is architecturally mapped to AArch64 System register [PMCCNTR\\_EL0](#).

External register PMCCNTR\_EL0 is architecturally mapped to AArch32 System register [PMCCNTR](#).

PMCCNTR\_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**

PMCCNTR\_EL0 is a 64-bit register.

**Field descriptions**

The PMCCNTR\_EL0 bit assignments are:

**CCNT, bits [63:0]**

Cycle count. Depending on the values of [PMCR\\_EL0](#).{LC, D}, the cycle count increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to [PMCR\\_EL0](#).C sets this field to 0.

This field resets to a value that is architecturally UNKNOWN.

**Accessing the PMCCNTR\_EL0:**

PMCCNTR\_EL0[31:0] can be accessed through the external debug interface:

Component	Offset
PMU	0x0F8

PMCCNTR\_EL0[63:32] can be accessed through the external debug interface:

Component	Offset
PMU	0x0FC

### I3.4.4 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

#### Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x000 to 0x01F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

#### ———— Note —————

This view of the register has previously been called PMCEID0\_EL0.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

#### Configurations

External register PMCEID0 is architecturally mapped to AArch64 System register [PMCEID0\\_EL0](#)[31:0].

External register PMCEID0[31:0] is architecturally mapped to AArch32 System register [PMCEID0](#).

PMCEID0 is in the Core power domain.

#### Attributes

PMCEID0 is a 32-bit register.

#### Field descriptions

The PMCEID0 bit assignments are:

#### ID[31:0], bits [31:0]

PMCEID0[n] maps to event n. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0 The common event is not implemented.

1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

### Accessing the PMCEID0:

PMCEID0 can be accessed through the external debug interface:

Component	Offset
PMU	0xE20

### I3.4.5 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

#### Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x020 to 0x03F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

#### ———— Note —————

This view of the register has previously been called PMCEID1\_EL0.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

#### Configurations

External register PMCEID1 is architecturally mapped to AArch64 System register [PMCEID1\\_EL0](#)[31:0].

External register PMCEID1[31:0] is architecturally mapped to AArch32 System register [PMCEID1](#).

PMCEID1 is in the Core power domain.

#### Attributes

PMCEID1 is a 32-bit register.

#### Field descriptions

The PMCEID1 bit assignments are:

#### ID[63:32], bits [31:0]

PMCEID1[n] maps to event (n + 32). For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0 The common event is not implemented.

1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

### Accessing the PMCEID1:

PMCEID1 can be accessed through the external debug interface:

Component	Offset
PMU	0xE24

### 13.4.6 PMCEID2, Performance Monitors Common Event Identification register 2

The PMCEID2 characteristics are:

**Purpose**

Defines which common architectural and common microarchitectural feature events in the range 0x4000 to 0x401F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

**Usage constraints**

This register is accessible as follows:

Off	DLK	OSLK	EPMAID	SLK	Default
Error	Error	Error	Error	RO	RO

**Configurations**

External register PMCEID2 is architecturally mapped to AArch64 System register [PMCEID0\\_EL0](#)[63:32].

External register PMCEID2[63:32] is architecturally mapped to AArch32 System register [PMCEID2](#).

PMCEID2 is in the Core power domain.

This register is introduced in ARMv8.1.

**Attributes**

PMCEID2 is a 32-bit register.

**Field descriptions**

The PMCEID2 bit assignments are:

**ID[16415:16384], bits [31:0]**

PMCEID2[31:0] maps to common events 0x4000 to 0x401F. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0           The common event is not implemented.

1           The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

### Accessing the PMCEID2:

PMCEID2 can be accessed through the external debug interface:

Component	Offset
PMU	0xE28

### I3.4.7 PMCEID3, Performance Monitors Common Event Identification register 3

The PMCEID3 characteristics are:

**Purpose**

Defines which common architectural and common microarchitectural feature events in the range 0x4020 to 0x403F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

**Usage constraints**

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

**Configurations**

External register PMCEID3 is architecturally mapped to AArch64 System register [PMCEID1\\_ELO](#)[63:32].

External register PMCEID3[63:32] is architecturally mapped to AArch32 System register [PMCEID3](#).

PMCEID3 is in the Core power domain.

This register is introduced in ARMv8.1.

**Attributes**

PMCEID3 is a 32-bit register.

**Field descriptions**

The PMCEID3 bit assignments are:

**ID[16447:16416], bits [31:0]**

PMCEID3[31:0] maps to common events 0x4020 to 0x403F. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0           The common event is not implemented.

1           The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

### Accessing the PMCEID3:

PMCEID3 can be accessed through the external debug interface:

Component	Offset
PMU	0xE2C

### I3.4.8 PMCFGR, Performance Monitors Configuration Register

The PMCFGR characteristics are:

**Purpose**

Contains PMU-specific configuration data.

**Usage constraints**

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

**Configurations**

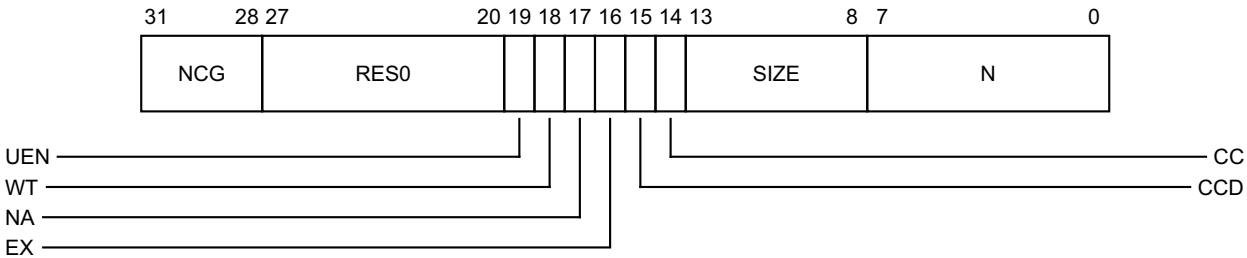

PMCFGR is in the Core power domain.

**Attributes**

PMCFGR is a 32-bit register.

**Field descriptions**

The PMCFGR bit assignments are:

**NCG, bits [31:28]**

This feature is not supported, so this field is RAZ.

**Bits [27:20]**

Reserved, RES0.

**UEN, bit [19]**

User-mode Enable Register supported. [PMUSERENR\\_EL0](#) is not visible in the external debug interface, so this bit is RAZ.

**WT, bit [18]**

This feature is not supported, so this bit is RAZ.

**NA, bit [17]**

This feature is not supported, so this bit is RAZ.

**EX, bit [16]**

Export supported. Value is IMPLEMENTATION DEFINED.

0 [PMCR\\_EL0.X](#) is RES0.

1 [PMCR\\_EL0.X](#) is read/write.

#### CCD, bit [15]

Cycle counter has prescale. This is RES1 if AArch32 is supported at any EL, and RAZ otherwise.

- 0 [PMCR\\_EL0.D](#) is RES0.
- 1 [PMCR\\_EL0.D](#) is read/write.

#### CC, bit [14]

Dedicated cycle counter (counter 31) supported. This bit is RAO.

#### SIZE, bits [13:8]

Size of counters. This field determines the spacing of counters in the memory-map.

In ARMv8 the counters are at doubleword-aligned addresses, and the largest counter is 64-bits, so this field is 0b111111.

#### N, bits [7:0]

Number of counters implemented in addition to the cycle counter, [PMCCNTR\\_EL0](#). The maximum number of event counters is 31.

- 00000000 Only [PMCCNTR\\_EL0](#) implemented.
- 00000001 [PMCCNTR\\_EL0](#) plus one event counter implemented.
- and so on up to 0b00011111, which indicates [PMCCNTR\\_EL0](#) and 31 event counters implemented.

#### Accessing the PMCFGR:

PMCFGR can be accessed through the external debug interface:

Component	Offset
PMU	0xE00

### I3.4.9 PMCIDR0, Performance Monitors Component Identification Register 0

The PMCIDR0 characteristics are:

**Purpose**

Provides information to identify a Performance Monitor component.  
For more information see [About the Component Identification scheme on page K2-6149](#).

**Usage constraints**

This register is accessible as follows:

SLK	Default
RO	RO

**Configurations**

PMCIDR0 is in the Debug power domain.  
Implementation of this register is OPTIONAL.  
This register is required for CoreSight compliance.

**Attributes**

PMCIDR0 is a 32-bit register.

**Field descriptions**

The PMCIDR0 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PRMBL\_0, bits [7:0]**

Preamble. Must read as 0x0D.

**Accessing the PMCIDR0:**

PMCIDR0 can be accessed through the external debug interface:

Component	Offset
PMU	0xFF0

### I3.4.10 PMCIDR1, Performance Monitors Component Identification Register 1

The PMCIDR1 characteristics are:

#### Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Component Identification scheme on page K2-6149](#).

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

PMCIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

#### Attributes

PMCIDR1 is a 32-bit register.

#### Field descriptions

The PMCIDR1 bit assignments are:

31	8	7	4	3	0
RES0					
CLASS			PRMBL_1		

#### Bits [31:8]

Reserved, RES0.

#### CLASS, bits [7:4]

Component class. Reads as 0x9, debug component.

#### PRMBL\_1, bits [3:0]

Preamble. RAZ.

#### Accessing the PMCIDR1:

PMCIDR1 can be accessed through the external debug interface:

Component	Offset
PMU	0xFF4

### I3.4.11 PMCIDR2, Performance Monitors Component Identification Register 2

The PMCIDR2 characteristics are:

**Purpose**

Provides information to identify a Performance Monitor component.  
For more information see [About the Component Identification scheme on page K2-6149](#).

**Usage constraints**

This register is accessible as follows:

SLK	Default
RO	RO

**Configurations**

PMCIDR2 is in the Debug power domain.  
Implementation of this register is OPTIONAL.  
This register is required for CoreSight compliance.

**Attributes**

PMCIDR2 is a 32-bit register.

**Field descriptions**

The PMCIDR2 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PRMBL\_2, bits [7:0]**

Preamble. Must read as 0x05.

**Accessing the PMCIDR2:**

PMCIDR2 can be accessed through the external debug interface:

Component	Offset
PMU	0xFF8

### I3.4.12 PMCIDR3, Performance Monitors Component Identification Register 3

The PMCIDR3 characteristics are:

#### Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Component Identification scheme on page K2-6149](#).

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

PMCIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

#### Attributes

PMCIDR3 is a 32-bit register.

#### Field descriptions

The PMCIDR3 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PRMBL\_3, bits [7:0]

Preamble. Must read as 0xB1.

#### Accessing the PMCIDR3:

PMCIDR3 can be accessed through the external debug interface:

Component	Offset
PMU	0xFFC

### I3.4.13 PMCID1SR, CONTEXTIDR\_EL1 Sample Register

The PMCID1SR characteristics are:

#### Purpose

Contains the sampled value of [CONTEXTIDR\\_EL1](#), captured on reading [PMPCSR](#)[31:0].

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

#### Configurations

PMCID1SR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is implemented. If the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented, this register is not implemented and the architecture defines the functionality in [EDCDSR](#).

This register is introduced in ARMv8.2.

#### Attributes

PMCID1SR is a 32-bit register.

#### Field descriptions

The PMCID1SR bit assignments are:

#### CONTEXTIDR\_EL1, bits [31:0]

Context ID. The value of [CONTEXTIDR](#) that is associated with the most recent [PMPCSR](#) sample.

- If EL1 is using AArch64, then the Context ID is held in [CONTEXTIDR\\_EL1](#).
- If EL1 is using AArch32, then the Context ID is held in [CONTEXTIDR](#).
- If EL3 is implemented and is using AArch32, then [CONTEXTIDR](#) is a banked register and PMCID1SR samples the current banked copy of [CONTEXTIDR](#) for the Security state that is associated with the most recent [PMPCSR](#) sample.

Because the value written to PMCID1SR is an indirect read of [CONTEXTIDR](#), therefore it is CONSTRAINED UNPREDICTABLE whether PMCID1SR is set to the original or new value if a read of [PMPCSR](#) samples:

- An instruction that writes to [CONTEXTIDR\\_EL1](#).
- The next Context synchronization event.
- Any instruction executed between these two instructions.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

### Accessing the PMCID1SR:

PMCID1SR can be accessed through the external debug interface:

Component	Offset
PMU	0x208
PMU	0x228

### I3.4.14 PMCID2SR, CONTEXTIDR\_EL2 Sample Register

The PMCID2SR characteristics are:

#### Purpose

Contains the sampled value of [CONTEXTIDR\\_EL2](#), captured on reading [PMPCSR](#)[31:0].

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

#### Configurations

PMCID2SR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is implemented. If the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented, this register is not implemented and the architecture defines the functionality in [EDCIDS](#).

If EL2 is not implemented, this register is RES0.

This register is introduced in ARMv8.2.

#### Attributes

PMCID2SR is a 32-bit register.

#### Field descriptions

The PMCID2SR bit assignments are:

#### CONTEXTIDR\_EL2, bits [31:0]

Context ID. The value of [CONTEXTIDR](#) that is associated with the most recent [PMPCSR](#) sample.

- If EL2 is using AArch64, then the Context ID is in [CONTEXTIDR\\_EL2](#).
- If EL2 is using AArch32, then this field is set to an UNKNOWN value.
- If [PMPCSR.NS](#)==0, this field is set to an UNKNOWN value.

Because the value written to PMCID2SR is an indirect read of [CONTEXTIDR](#), therefore it is CONSTRAINED UNPREDICTABLE whether PMCID2SR is set to the original or new value if a read of [PMPCSR](#) samples:

- An instruction that writes to [CONTEXTIDR\\_EL2](#).
- The next Context synchronization event.
- Any instruction executed between these two instructions.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

### Accessing the PMCID2SR:

PMCID2SR can be accessed through the external debug interface:

Component	Offset
PMU	0x22C

### I3.4.15 PMCNTENCLR\_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR\_EL0 characteristics are:

## Purpose

Disables the Cycle Count Register, **PMCCNTR\_EL0**, and any implemented event counters **PMEVCNTR<n>**. Reading this register shows which counters are enabled.

## Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

## Configurations

External register `PMCNTENCLR_EL0` is architecturally mapped to AArch64 System register `PMCNTENCLR_EL0`.

External register PMCNTENCLR\_ELO is architecturally mapped to AArch32 System register [PMCNTENCLR](#).

PMCNTENCLR\_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

### Attributes

PMCNTENCLR\_EL0 is a 32-bit register.

## Field descriptions

The PMCNTENCLR EL0 bit assignments are:

**C, bit [31]**

**PMCCNTR\_ELO** disable bit. Disables the cycle counter register. Possible values are:

- |   |  |
|---|--|
| 0 | When read, means the cycle counter is disabled. When written, has no effect.             |
| 1 | When read, means the cycle counter is enabled. When written, disables the cycle counter. |

This field resets to a value that is architecturally UNKNOWN.

**P<n>, bit [n], for n = 0 to 30**

Event counter disable bit for **PMEVCNTR<n>** EL0.

Bits [30:N] are RAZ/WI. N is the value in **PMCFGR.N**.

Possible values of each bit are:

- |   |  |
|---|--|
| 0 | When read, means that <b>PMEVCNTR&lt;n&gt;_EL0</b> is disabled. When written, has no effect.                         |
| 1 | When read, means that <b>PMEVCNTR&lt;n&gt;_EL0</b> is enabled. When written, disables <b>PMEVCNTR&lt;n&gt;_EL0</b> . |

This field resets to a value that is architecturally UNKNOWN.

### Accessing the PMCNTENCLR\_EL0:

PMCNTENCLR\_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xC20

### I3.4.16 PMCNTENSET\_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET\_EL0 characteristics are:

#### Purpose

Enables the Cycle Count Register, [PMCCNTR\\_EL0](#), and any implemented event counters [PMEVCNTR<n>](#). Reading this register shows which counters are enabled.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

#### Configurations

External register PMCNTENSET\_EL0 is architecturally mapped to AArch64 System register [PMCNTENSET\\_EL0](#).

External register PMCNTENSET\_EL0 is architecturally mapped to AArch32 System register [PMCNTENSET](#).

PMCNTENSET\_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

#### Attributes

PMCNTENSET\_EL0 is a 32-bit register.

#### Field descriptions

The PMCNTENSET\_EL0 bit assignments are:

#### C, bit [31]

[PMCCNTR\\_EL0](#) enable bit. Enables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, enables the cycle counter.

This field resets to a value that is architecturally UNKNOWN.

#### P<n>, bit [n], for n = 0 to 30

Event counter enable bit for [PMEVCNTR<n>\\_EL0](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>\\_EL0](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>\\_EL0](#) event counter is enabled. When written, enables [PMEVCNTR<n>\\_EL0](#).

This field resets to a value that is architecturally UNKNOWN.

### Accessing the PMCNTENSET\_EL0:

PMCNTENSET\_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xC00

### I3.4.17 PMCR\_EL0, Performance Monitors Control Register

The PMCR\_EL0 characteristics are:

## Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

## Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA D	SLK	Default
Error	Error	Error	Error	RO	RW

## Configurations

External register PMCR\_EL0[6:0] is architecturally mapped to AArch32 System register [PMCR](#)[6:0].

External register PMCR\_EL0[6:0] is architecturally mapped to AArch64 System register [PMCR\\_EL0\[6:0\]](#).

PMCR\_EL0 is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

This register is only partially mapped to the internal **PMCR** System register. An external agent must use other means to discover the information held in **PMCR**[31:11], such as accessing **PMCFGR** and the ID registers.

### Attributes

PMCR\_EL0 is a 32-bit register.

## Field descriptions

The PMCR EL0 bit assignments are:

31	11	10	7	6	5	4	3	2	1	0
RAZ/WI			RES0	LC	DP	X	D	C	P	E

**Bits [31:11]**

RAZ/WI. Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

**Bits [10:7]**

Reserved, RES0.

**LC, bit [6]**

Long cycle counter enable. Determines which **PMCCNTR\_EL0** bit generates an overflow recorded by **PMOVSr**[31].

0	Cycle counter overflow on increment that changes <b>PMCCNTR_EL0</b> [31] from 1 to 0.
---	---

1 Cycle counter overflow on increment that changes **PMCCNTR\_EL0**[63] from 1 to 0.

ARM deprecates use of PMCR EL0.LC = 0.

In an AArch64-only implementation, this field is RES1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

#### DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

- 0 [PMCCNTR\\_EL0](#), if enabled, counts when event counting is prohibited.
- 1 [PMCCNTR\\_EL0](#) does not count when event counting is prohibited.

Counting events is never prohibited in Non-secure state. However, there are some restrictions on counting events in Secure state. For more information about the interaction between the Performance Monitors and EL3, see [Interaction with EL3 on page D5-2145](#).

When EL3 is not implemented, this field is RES0:

- When [ARMv8.1-PMU](#) is not implemented.
- When [ARMv8.1-PMU](#) is implemented, only if EL2 is not implemented.

Otherwise this field is RW.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:

- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

#### X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

- 0 Do not export events.
- 1 Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL trace macrocell. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:

- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

#### D, bit [3]

Clock divider. The possible values of this bit are:

- 0 When enabled, [PMCCNTR\\_EL0](#) counts every clock cycle.
- 1 When enabled, [PMCCNTR\\_EL0](#) counts once every 64 clock cycles.

In an AArch64-only implementation this field is RES0, otherwise it is an RW field. If  $\text{PMCR\_EL0.LC} = 1$ , this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of  $\text{PMCR\_EL0.D} = 1$ .

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:

- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

#### C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset [PMCCNTR\\_EL0](#) to zero.

This bit is always RAZ.

Resetting [PMCCNTR\\_EL0](#) does not clear the [PMCCNTR\\_EL0](#) overflow bit to 0.

#### P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset all event counters, not including [PMCCNTR\\_EL0](#), to zero.

This bit is always RAZ.

Resetting the event counters does not clear any overflow bits to 0.

#### E, bit [0]

Enable. The possible values of this bit are:

- 0 All counters, including [PMCCNTR\\_EL0](#), are disabled.
- 1 All counters are enabled by [PMCNTENSET\\_EL0](#).

This bit is RW.

When this register has an architecturally-defined reset value, this field resets to 0.

#### Accessing the PMCR\_EL0:

PMCR\_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xE04

### I3.4.18 PMDEVAFF0, Performance Monitors Device Affinity register 0

The PMDEVAFF0 characteristics are:

#### Purpose

Copy of the low half of the PE [MPIDR\\_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

PMDEVAFF0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

#### Attributes

PMDEVAFF0 is a 32-bit register.

#### Field descriptions

The PMDEVAFF0 bit assignments are:

#### Bits [31:0]

[MPIDR\\_EL1](#) low half. Read-only copy of the low half of [MPIDR\\_EL1](#), as seen from the highest implemented Exception level.

#### Accessing the PMDEVAFF0:

PMDEVAFF0 can be accessed through the external debug interface:

Component	Offset
PMU	0xFA8

### I3.4.19 PMDEVAFF1, Performance Monitors Device Affinity register 1

The PMDEVAFF1 characteristics are:

**Purpose**

Copy of the high half of the PE [MPIDR\\_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

**Usage constraints**

This register is accessible as follows:

SLK	Default
RO	RO

**Configurations**

PMDEVAFF1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

**Attributes**

PMDEVAFF1 is a 32-bit register.

**Field descriptions**

The PMDEVAFF1 bit assignments are:

**Bits [31:0]**

[MPIDR\\_EL1](#) high half. Read-only copy of the high half of [MPIDR\\_EL1](#), as seen from the highest implemented Exception level.

**Accessing the PMDEVAFF1:**

PMDEVAFF1 can be accessed through the external debug interface:

Component	Offset
PMU	0xFAC

### I3.4.20 PMDEVARCH, Performance Monitors Device Architecture register

The PMDEVARCH characteristics are:

#### Purpose

Identifies the programmers' model architecture of the Performance Monitor component.

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

PMDEVARCH is in the Debug power domain.

#### Attributes

PMDEVARCH is a 32-bit register.

#### Field descriptions

The PMDEVARCH bit assignments are:

#### ARCHITECT, bits [31:21]

Defines the architecture of the component. For Performance Monitors, this is ARM Limited.

Bits [31:28] are the JEP106 continuation code, 0x4.

Bits [27:21] are the JEP106 ID code, 0x3B.

#### PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in ARMv8.

#### REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For Performance Monitors, the revision defined by ARMv8 is 0x0.

All other values are reserved.

#### ARCHID, bits [15:0]

Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided.

For Performance Monitors:

- Bits [15:12] are the architecture version, 0x2.
- Bits [11:0] are the architecture part number, 0xA16.

This corresponds to Performance Monitors architecture version PMUv3.

---

**Note**

---

The PMUv3 memory-mapped programmers' model can be used by devices other than ARMv8 processors. Software must determine whether the PMU is attached to an ARMv8 processor by using the [PMDEVAF0](#) and [PMDEVAF1](#) registers to discover the affinity of the PMU to any ARMv8 processors.

---

**Accessing the PMDEVARCH:**

PMDEVARCH can be accessed through the external debug interface:

Component	Offset
PMU	0xFBC

### I3.4.21 PMDEVID, Performance Monitors Device ID register

The PMDEVID characteristics are:

#### Purpose

Provides information about features of the debug implementation.

#### Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

#### Configurations

PMDEVID is in the Debug power domain.

This register is required in all implementations.

Up until and including ARMv8.1, the architecture defines the functionality in a different set of registers, see [DBGDEVID](#).

#### Attributes

PMDEVID is a 32-bit register.

#### Field descriptions

The PMDEVID bit assignments are:

#### Bits [31:4]

Reserved, RES0.

#### PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using performance monitor registers. Permitted values of this field are:

- 0000 Architecture-defined form of PC Sample-based Profiling not implemented with performance monitor registers.
- 0001 Architecture-defined form of PC Sample-based Profiling is implemented with performance monitor registers.

All other values are reserved.

#### Accessing the PMDEVID:

PMDEVID can be accessed through the external debug interface:

Component	Offset
PMU	0xFC8

## I3.4.22 PMDEVTYPE, Performance Monitors Device Type register

The PMDEVTYPE characteristics are:

### Purpose

Indicates to a debugger that this component is part of a PE's performance monitor interface.

### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

### Configurations

PMDEVTYPE is in the Debug power domain.

Implementation of this register is OPTIONAL.

### Attributes

PMDEVTYPE is a 32-bit register.

### Field descriptions

The PMDEVTYPE bit assignments are:

31	8	7	4	3	0
RES0				SUB	MAJOR

#### Bits [31:8]

Reserved, RES0.

#### SUB, bits [7:4]

Subtype. Must read as 0x1 to indicate this is a component within a PE.

#### MAJOR, bits [3:0]

Major type. Must read as 0x6 to indicate this is a performance monitor component.

### Accessing the PMDEVTYPE:

PMDEVTYPE can be accessed through the external debug interface:

Component	Offset
PMU	0xFCC

### I3.4.23 PMEVCNTR<n>\_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>\_EL0 characteristics are:

#### Purpose

Holds event counter n, which counts events, where n is 0 to 30.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

External accesses to the performance monitors ignore [PMUSERENR\\_EL0](#) and, if implemented, [MDCR\\_EL2](#).{TPM, TPMCR, HPMN} and [MDCR\\_EL3](#).TPM. This means that all counters are accessible regardless of the current EL or privilege of the access.

#### Configurations

External register PMEVCNTR<n>\_EL0 is architecturally mapped to AArch64 System register [PMEVCNTR<n>\\_EL0](#).

External register PMEVCNTR<n>\_EL0 is architecturally mapped to AArch32 System register [PMEVCNTR<n>](#).

PMEVCNTR<n>\_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

#### Attributes

PMEVCNTR<n>\_EL0 is a 32-bit register.

#### Field descriptions

The PMEVCNTR<n>\_EL0 bit assignments are:

#### Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

This field resets to a value that is architecturally UNKNOWN.

#### Accessing the PMEVCNTR<n>\_EL0:

PMEVCNTR<n>\_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0x000 + 8n

### I3.4.24 PMEVTYPER<n>\_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>\_EL0 characteristics are:

#### Purpose

Configures event counter n, where n is 0 to 30.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

#### Configurations

External register PMEVTYPER<n>\_EL0 is architecturally mapped to AArch64 System register [PMEVTYPER<n>\\_EL0](#).

External register PMEVTYPER<n>\_EL0 is architecturally mapped to AArch32 System register [PMEVTYPER<n>](#).

PMEVTYPER<n>\_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

#### Attributes

PMEVTYPER<n>\_EL0 is a 32-bit register.

#### Field descriptions

The PMEVTYPER<n>\_EL0 bit assignments are:

#### P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count events in EL1.
- 1 Do not count events in EL1.

This field resets to a value that is architecturally UNKNOWN.

#### U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count events in EL0.
- 1 Do not count events in EL0.

This field resets to a value that is architecturally UNKNOWN.

#### NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

This field resets to a value that is architecturally UNKNOWN.

#### NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

This field resets to a value that is architecturally UNKNOWN.

#### NSH, bit [27]

Non-secure EL2 (Hypervisor) filtering. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count events in EL2.

1 Count events in EL2.

This field resets to a value that is architecturally UNKNOWN.

#### M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to 0.

#### ————— Note —————

This field is not visible in the AArch32 PMEVTYPEPER System register.

This field resets to a value that is architecturally UNKNOWN.

#### MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

0 Count events only on controlling PE.

1 Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

#### ————— Note —————

- An implementation is described as multi-threaded when the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, the value of MPIDR\_EL1.MT, when read at the highest implemented Exception level, is 1.
- Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

This field resets to a value that is architecturally UNKNOWN.

#### Bits [24:16]

Reserved, RES0.

#### evtCount[15:10], bits [15:10]

##### *In ARMv8.2 and ARMv8.1*

Extension to evtCount[9:0]. See evtCount[9:0] for more details.

This field resets to a value that is architecturally UNKNOWN.

##### *In ARMv8.0.*

Reserved, RES0.

#### evtCount[9:0], bits [9:0]

Event to count. The event number of the event that is counted by event counter [PMEVCNTR<n>\\_EL0](#).

Software must program this field with an event that is supported by the PE being programmed.

There are three ranges of event numbers:

- Event numbers in the range 0x000 to 0x03F are common architectural and microarchitectural events.
- Event numbers in the range 0x040 to 0x0BF are ARM recommended common architectural and microarchitectural events.
- Event numbers in the range 0x0C0 to 0x3FF are IMPLEMENTATION DEFINED events.

If evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the event type:

- For the range 0x000 to 0x03F, no events are counted, and the value returned by a direct or external read of the evtCount field is the value written to the field.
- For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the evtCount field is UNKNOWN.

#### ————— **Note** —————

UNPREDICTABLE means the event must not expose privileged information.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

This field resets to a value that is architecturally UNKNOWN.

#### Accessing the PMEVTYPER<n>\_EL0:

PMEVTYPER<n>\_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0x400 + 4n

### I3.4.25 PMINTENCLR\_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR\_EL1 characteristics are:

#### Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR\\_ELO](#), and the event counters [PMEVCNTR<n>\\_ELO](#). Reading the register shows which overflow interrupt requests are enabled.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

#### Configurations

External register PMINTENCLR\_EL1 is architecturally mapped to AArch64 System register [PMINTENCLR\\_EL1](#).

External register PMINTENCLR\_EL1 is architecturally mapped to AArch32 System register [PMINTENCLR](#).

PMINTENCLR\_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

#### Attributes

PMINTENCLR\_EL1 is a 32-bit register.

#### Field descriptions

The PMINTENCLR\_EL1 bit assignments are:

#### C, bit [31]

[PMCCNTR\\_ELO](#) overflow interrupt request disable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

This field resets to a value that is architecturally UNKNOWN.

#### P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request disable bit for [PMEVCNTR<n>\\_ELO](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values are:

- 0 When read, means that the [PMEVCNTR<n>\\_ELO](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<n>\\_ELO](#) event counter interrupt request is enabled. When written, disables the [PMEVCNTR<n>\\_ELO](#) interrupt request.

This field resets to a value that is architecturally UNKNOWN.

### Accessing the PMINTENCLR\_EL1:

PMINTENCLR\_EL1 can be accessed through the external debug interface:

Component	Offset
PMU	0xC60

### I3.4.26 PMINTENSET\_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET\_EL1 characteristics are:

#### Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR\\_ELO](#), and the event counters [PMEVCNTR<n>\\_ELO](#). Reading the register shows which overflow interrupt requests are enabled.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

#### Configurations

External register PMINTENSET\_EL1 is architecturally mapped to AArch64 System register [PMINTENSET\\_EL1](#).

External register PMINTENSET\_EL1 is architecturally mapped to AArch32 System register [PMINTENSET](#).

PMINTENSET\_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

#### Attributes

PMINTENSET\_EL1 is a 32-bit register.

#### Field descriptions

The PMINTENSET\_EL1 bit assignments are:

#### C, bit [31]

[PMCCNTR\\_ELO](#) overflow interrupt request enable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

This field resets to a value that is architecturally UNKNOWN.

#### P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request enable bit for [PMEVCNTR<n>\\_ELO](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values are:

- 0 When read, means that the [PMEVCNTR<n>\\_ELO](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<n>\\_ELO](#) event counter interrupt request is enabled. When written, enables the [PMEVCNTR<n>\\_ELO](#) interrupt request.

This field resets to a value that is architecturally UNKNOWN.

### Accessing the PMINTENSET\_EL1:

PMINTENSET\_EL1 can be accessed through the external debug interface:

Component	Offset
PMU	0xC40

### I3.4.27 PMITCTRL, Performance Monitors Integration mode Control register

The PMITCTRL characteristics are:

#### Purpose

Enables the Performance Monitors to switch from default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
IMP DEF	IMP DEF	IMP DEF	RW

#### Configurations

It is IMPLEMENTATION DEFINED whether PMITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Implementation of this register is OPTIONAL.

#### Attributes

PMITCTRL is a 32-bit register.

#### Field descriptions

The PMITCTRL bit assignments are:

#### Bits [31:1]

Reserved, RES0.

#### IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

0 Normal operation.

1 Integration mode enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

### Accessing the PMITCTRL:

PMITCTRL can be accessed through the external debug interface:

Component	Offset
PMU	0xF00

## I3.4.28 PMLAR, Performance Monitors Lock Access Register

The PMLAR characteristics are:

### Purpose

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

### Usage constraints

This register is accessible as follows:

Default
WO

### Configurations

PMLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software Lock can be implemented as part of CoreSight compliance.

PMLAR ignores writes if the Software Lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses PMLAR to set or clear the lock, and [PMLSR](#) to check the current status of the lock.

### Attributes

PMLAR is a 32-bit register.

### Field descriptions

The PMLAR bit assignments are:

### KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

### Accessing the PMLAR:

PMLAR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
PMU	0xFB0

### I3.4.29 PMLSR, Performance Monitors Lock Status Register

The PMLSR characteristics are:

**Purpose**

Indicates the current status of the software lock for Performance Monitors registers.

**Usage constraints**

This register is accessible as follows:

Default
RO

**Configurations**

PMLSR is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software Lock can be implemented as part of CoreSight compliance.

PMLSR is RAZ if the Software Lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses [PMLAR](#) to set or clear the lock, and PMLSR to check the current status of the lock.

**Attributes**

PMLSR is a 32-bit register.

**Field descriptions**

The PMLSR bit assignments are:

**Bits [31:3]**

Reserved, RES0.

**nTT, bit [2]**

Not thirty-two bit access required. RAZ.

**SLK, bit [1]**

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

- 0 Lock clear. Writes are permitted to this component's registers.
- 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

When this register has an architecturally-defined reset value, this field resets to 1.

#### SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED.

Permitted values are:

- 0 Software Lock not implemented or not memory-mapped access.
- 1 Software Lock implemented and memory-mapped access.

#### Accessing the PMLSR:

PMLSR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
PMU	0xFB4

### I3.4.30 PMOVSCLR\_EL0, Performance Monitors Overflow Flag Status Clear register

The PMOVSCLR\_EL0 characteristics are:

#### Purpose

Contains the state of the overflow bit for the Cycle Count Register, [PMCCNTR\\_EL0](#), and each of the implemented event counters [PMEVCNTR<n>](#). Writing to this register clears these bits.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

#### Configurations

External register PMOVSCLR\_EL0 is architecturally mapped to AArch64 System register [PMOVSCLR\\_EL0](#).

External register PMOVSCLR\_EL0 is architecturally mapped to AArch32 System register [PMOVSRR](#).

PMOVSCLR\_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

#### Attributes

PMOVSCLR\_EL0 is a 32-bit register.

#### Field descriptions

The PMOVSCLR\_EL0 bit assignments are:

#### C, bit [31]

[PMCCNTR\\_EL0](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

[PMCR\\_EL0](#).LC controls whether an overflow is detected from [PMCCNTR\\_EL0](#)[31] or from [PMCCNTR\\_EL0](#)[63].

This field resets to a value that is architecturally UNKNOWN.

#### P<n>, bit [n], for n = 0 to 30

Event counter overflow clear bit for [PMEVCNTR<n>\\_EL0](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>\\_EL0](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>\\_EL0](#) has overflowed. When written, clears the [PMEVCNTR<n>\\_EL0](#) overflow bit to 0.

This field resets to a value that is architecturally UNKNOWN.

#### Accessing the PMOVSLR\_EL0:

PMOVSLR\_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xC80

### I3.4.31 PMOVSSET\_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSET\_EL0 characteristics are:

## Purpose

Sets the state of the overflow bit for the Cycle Count Register, **PMCCNTR\_EL0**, and each of the implemented event counters **PMEVCNTR<n>**.

## Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

## Configurations

External register PMOVSSET\_EL0 is architecturally mapped to AArch64 System register **PMOVSSET\_EL0**.

External register PMOVSSET\_EL0 is architecturally mapped to AArch32 System register [PMOVSSET](#).

PMOVSSET\_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

### Attributes

PMOVSSET EL0 is a 32-bit register.

## Field descriptions

The PMOVSSET EL0 bit assignments are:

**C, bit [31]**

**PMCCNTR\_ELO** overflow bit. Possible values are:

- |   |  |
|---|--|
| 0 | When read, means the cycle counter has not overflowed. When written, has no effect.          |
| 1 | When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1. |

This field resets to a value that is architecturally UNKNOWN.

**P<n>, bit [n], for n = 0 to 30**

Event counter overflow set bit for **PMEVCNTR<n>** EL0.

Bits [30:N] are RAZ/WI. N is the value in **PMCFGR.N**.

Possible values are:

- |   |   |
|---|---|
| 0 | When read, means that <b>PMEVCNTR&lt;n&gt;_EL0</b> has not overflowed. When written, has no effect.                                       |
| 1 | When read, means that <b>PMEVCNTR&lt;n&gt;_EL0</b> has overflowed. When written, sets the <b>PMEVCNTR&lt;n&gt;_EL0</b> overflow bit to 1. |

This field resets to a value that is architecturally UNKNOWN.

### Accessing the PMOVSSET\_EL0:

PMOVSSET\_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xCC0

### I3.4.32 PMPCSR, Program Counter Sample Register

The PMPCSR characteristics are:

#### Purpose

Holds a sampled instruction address value.

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

#### Configurations

PMPCSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is implemented.

Support for 64-bit atomic reads is IMPLEMENTATION DEFINED. If 64-bit atomic reads are implemented, a 64-bit read of PMPCSR has the same side-effect as a 32-bit read of PMCSR[31:0] followed by a 32-bit read of PMPCSR[63:32], returning the combined value. For example, if the PE is in Debug state then a 64-bit atomic read returns bits[31:0] == 0xFFFFFFFF and bits[63:32] UNKNOWN.

If the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented, this register is not implemented and the architecture defines the functionality in [EDPCSR](#).

This register is introduced in ARMv8.2.

#### Attributes

PMPCSR is a 64-bit register.

#### Field descriptions

The PMPCSR bit assignments are:

#### NS, bit [63]

Non-secure state sample. Indicates the Security state that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

#### EL, bits [62:61]

Exception level status sample. Indicates the Exception level that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

00 Sample is from EL0.

01 Sample is from EL1.

10 Sample is from EL2.

11 Sample is from EL3.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

#### Bits [60:56]

Reserved, RES0.

#### PC Sample[55:32], bits [55:32]

Bits[55:32] of the sampled instruction address value. The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

#### PC Sample[31:0], bits [31:0]

Bits[31:0] of the sampled instruction address value. The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

- For a read of PMPCSR[31:0] from the memory-mapped interface, if [PMLSR.SLK](#) == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of PMPCSR[31:0] has the side-effect of indirectly writing to PMPCSR[63:32], [PMCID1SR](#), [PMCID2SR](#), and [PMVIDSR](#):
  - If the PE is in Debug state, or PC Sample-based profiling is prohibited, PMPCSR[31:0] reads as 0xFFFFFFFF, and PMPCSR[63:32], [PMCID1SR](#), [PMCID2SR](#), and [PMVIDSR](#) become UNKNOWN.
  - If the PE is in Reset state, the sampled value is UNKNOWN and PMPCSR[63:32], [PMCID1SR](#), [PMCID2SR](#), and [PMVIDSR](#) become UNKNOWN.
  - If no instruction has been retired since the PE left Reset state, Debug state, or a state where PC Sample-based Profiling is prohibited, the sampled value is UNKNOWN, and PMPCSR[63:32], [PMCID1SR](#), [PMCID2SR](#), and [PMVIDSR](#) become UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

### Accessing the PMPCSR:

PMPCSR[31:0] can be accessed through the external debug interface:

Component	Offset
PMU	0x200
PMU	0x220

PMPCSR[63:32] can be accessed through the external debug interface:

Component	Offset
PMU	0x204
PMU	0x224

### I3.4.33 PMPIDR0, Performance Monitors Peripheral Identification Register 0

The PMPIDR0 characteristics are:

**Purpose**

Provides information to identify a Performance Monitor component.  
For more information see [About the Peripheral identification scheme on page K2-6146](#).

**Usage constraints**

This register is accessible as follows:

SLK	Default
RO	RO

**Configurations**

PMPIDR0 is in the Debug power domain.  
Implementation of this register is OPTIONAL.  
This register is required for CoreSight compliance.

**Attributes**

PMPIDR0 is a 32-bit register.

**Field descriptions**

The PMPIDR0 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PART\_0, bits [7:0]**

Part number, least significant byte.

**Accessing the PMPIDR0:**

PMPIDR0 can be accessed through the external debug interface:

Component	Offset
PMU	0xFE0

### I3.4.34 PMPIDR1, Performance Monitors Peripheral Identification Register 1

The PMPIDR1 characteristics are:

#### Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

PMPIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

#### Attributes

PMPIDR1 is a 32-bit register.

#### Field descriptions

The PMPIDR1 bit assignments are:

31	8	7	4	3	0
RES0					
			DES_0		PART_1

#### Bits [31:8]

Reserved, RES0.

#### DES\_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.

#### PART\_1, bits [3:0]

Part number, most significant nibble.

#### Accessing the PMPIDR1:

PMPIDR1 can be accessed through the external debug interface:

Component	Offset
PMU	0xFE4

### I3.4.35 PMPIDR2, Performance Monitors Peripheral Identification Register 2

The PMPIDR2 characteristics are:

#### Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

PMPIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

#### Attributes

PMPIDR2 is a 32-bit register.

#### Field descriptions

The PMPIDR2 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

#### JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

#### DES\_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

#### Accessing the PMPIDR2:

PMPIDR2 can be accessed through the external debug interface:

Component	Offset
PMU	0xFE8

### I3.4.36 PMPIDR3, Performance Monitors Peripheral Identification Register 3

The PMPIDR3 characteristics are:

#### Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

PMPIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

#### Attributes

PMPIDR3 is a 32-bit register.

#### Field descriptions

The PMPIDR3 bit assignments are:

31	8	7	4	3	0
RES0				REVAND	CMOD

#### Bits [31:8]

Reserved, RES0.

#### REVAND, bits [7:4]

Part minor revision. Parts using [PMPIDR2.REVISION](#) as an extension to the Part number must use this field as a major revision number.

#### CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

#### Accessing the PMPIDR3:

PMPIDR3 can be accessed through the external debug interface:

Component	Offset
PMU	0xFEC

### I3.4.37 PMPIDR4, Performance Monitors Peripheral Identification Register 4

The PMPIDR4 characteristics are:

#### Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

#### Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

#### Configurations

PMPIDR4 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

#### Attributes

PMPIDR4 is a 32-bit register.

#### Field descriptions

The PMPIDR4 bit assignments are:

31	8	7	4	3	0
RES0				SIZE	DES_2

#### Bits [31:8]

Reserved, RES0.

#### SIZE, bits [7:4]

Size of the component. RAZ.  $\log_2$  of the number of 4KB pages from the start of the component to the end of the component ID registers.

#### DES\_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

#### Accessing the PMPIDR4:

PMPIDR4 can be accessed through the external debug interface:

Component	Offset
PMU	0xFD0

### I3.4.38 PMSWINC\_EL0, Performance Monitors Software Increment register

The PMSWINC\_EL0 characteristics are:

#### Purpose

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see [SW\\_INCR](#).

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	WI	WO

#### Configurations

External register PMSWINC\_EL0 is architecturally mapped to AArch64 System register [PMSWINC\\_EL0](#).

External register PMSWINC\_EL0 is architecturally mapped to AArch32 System register [PMSWINC](#).

PMSWINC\_EL0 is in the Core power domain.

Implementation of this register is OPTIONAL.

If this register is implemented, use of it is deprecated.

If 1 is written to bit [n] from the external debug interface, it is CONSTRAINED UNPREDICTABLE whether or not a SW\_INCR event is created for counter n. This is consistent with not implementing the register in the external debug interface.

#### Attributes

PMSWINC\_EL0 is a 32-bit register.

#### Field descriptions

The PMSWINC\_EL0 bit assignments are:

#### Bit [31]

Reserved, RES0.

#### P<n>, bit [n], for n = 0 to 30

Event counter software increment bit for [PMEVCNTR<n>\\_EL0](#).

P<n> is WI if n >= [PMCR\\_EL0.N](#), the number of implemented counters.

Otherwise, the effects of writing to this bit are:

- 0 No action. The write to this bit is ignored.
- 1 It is CONSTRAINED UNPREDICTABLE whether a SW\_INCR event is generated for event counter n.

### Accessing the PMSWINC\_EL0:

PMSWINC\_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xCA0

### I3.4.39 PMVIDSR, VMID Sample Register

The PMVIDSR characteristics are:

#### Purpose

Contains the sampled VMID value that is captured on reading [PMPCSR](#)[31:0].

#### Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

#### Configurations

PMVIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is implemented. If the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented, this register is not implemented and the architecture defines the functionality in [EDVIDSR](#).

If EL2 is not implemented, this register is RES0.

This register is introduced in ARMv8.2.

#### Attributes

PMVIDSR is a 32-bit register.

#### Field descriptions

The PMVIDSR bit assignments are:

#### Bits [31:16]

Reserved, RES0.

#### VMID, bits [15:0]

VMID sample. The VMID associated with the most recent [PMPCSR](#) sample.

- If EL2 is implemented and is using AArch64, then the VMID is held in [VTTBR\\_EL2](#).VMID.
- If EL2 is implemented and is using AArch32, then the VMID is held in [VTTBR](#).VMID.
- This field is set to an UNKNOWN value if:
  - [PMPCSR](#).NS == 0.
  - [PMPCSR](#).EL == 0b10.
  - [PMPCSR](#).NS == 1, [PMPCSR](#).EL == 0b00, EL2 is using AArch64, [HCR\\_EL2](#).E2H == 1, and [HCR\\_EL2](#).TGE == 1.
- If EL2 is not implemented, then this field is RES0.
- If 16-bit VMIDs are not supported, PMVIDSR.VMID[15:8] is RES0.

- If 16-bit VMIDs are supported, but VTTBRx.VMID[15:8] are not used, PMVIDSR.VMID[15:8] is set to 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

#### Accessing the PMVIDSR:

PMVIDSR can be accessed through the external debug interface:

Component	Offset
PMU	0x20C

## I3.5 Generic Timer memory-mapped registers overview

The Generic Timer memory-mapped registers are implemented as multiple register frames, with each register frame having its own base address, as follows:

- A single CNTCTLBase register frame, at base address CNTCTLBase.
- Between one and seven CNTBaseN register frames, each with its own base address CNTBaseN.
- For each CNTBaseN register frame, if required, a CNTEL0BaseN register frame, at base address CNTEL0BaseN, that provides an EL0 view of the CNTBaseN register frame.

For more information, see:

- [Memory-mapped timer components on page I1-5730.](#)
- [The CNTBaseN and CNTEL0BaseN frames on page I1-5732.](#) This section includes the memory map of the CNTBaseN and CNTEL0BaseN register frames.
- [The CNTCTLBase frame on page I1-5731.](#) This section includes the memory map of the CNTCTLBase register frame.
- [Providing a complete set of counter and timer features on page I1-5734.](#)

## I3.6 Generic Timer memory-mapped register descriptions

This section describes the Generic Timer registers. [Generic Timer memory-mapped registers overview on page I3-5815](#) gives an overview of these registers, and includes links to their memory maps.

### I3.6.1 CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7

The CNTACR<n> characteristics are:

#### Purpose

Provides top-level access controls for the elements of a timer frame. CNTACR<n> provides the controls for frame CNTBaseN.

In addition to the CNTACR<n> control:

- CNTNSAR controls whether CNTACR<n> is accessible by Non-secure accesses.
- If frame CNTEL0BaseN is implemented, the CNTEL0ACR in frame CNTBaseN provides additional control of accesses to frame CNTEL0BaseN.

#### Usage constraints

This register is accessible as follows:

Default
RW

In a system that recognizes two Security states:

- CNTACR<n> is always accessible by Secure accesses.
- CNTNSAR.NS<n> determines whether CNTACR<n> is accessible by Non-secure accesses.

#### Configurations

The power domain of CNTACR<n> is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer](#) on page I1-5724.

Implemented only if the value of CNTTIDR.Frame<n> is 1.

An implementation of the counters might not provide configurable access to some or all of the features. In this case, the associated field in the CNTACR<n> register is:

- RAZ/WI if access is always denied.
- RAO/WI if access is always permitted.

#### Attributes

CNTACR<n> is a 32-bit register.

#### Field descriptions

The CNTACR<n> bit assignments are:

#### Bits [31:6]

Reserved, RES0.

#### RWPT, bit [5]

Read/write access to the EL1 Physical Timer registers [CNTP\\_CVAL](#), [CNTP\\_TVAL](#), and [CNTP\\_CTL](#), in frame <n>. The possible values of this bit are:

- 0 No access to the EL1 Physical Timer registers in frame <n>. The registers are RES0.
- 1 Read/write access to the EL1 Physical Timer registers in frame <n>.

#### RWVT, bit [4]

Read/write access to the Virtual Timer register [CNTV\\_CVAL](#), [CNTV\\_TVAL](#), and [CNTV\\_CTL](#), in frame <n>. The possible values of this bit are:

- 0 No access to the Virtual Timer registers in frame <n>. The registers are RES0.
- 1 Read/write access to the Virtual Timer registers in frame <n>.

#### RVOFF, bit [3]

Read-only access to [CNTVOFF](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTVOFF](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTVOFF](#) in frame <n>.

#### RFRQ, bit [2]

Read-only access to [CNTFRQ](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTFRQ](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTFRQ](#) in frame <n>.

#### RVCT, bit [1]

Read-only access to [CNTVCT](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTVCT](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTVCT](#) in frame <n>.

#### RPCT, bit [0]

Read-only access to [CNTPCT](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTPCT](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTPCT](#) in frame <n>.

### Accessing the CNTACR<n>:

CNTACR<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x040 + 4n

## I3.6.2 CNTCR, Counter Control Register

The CNTCR characteristics are:

### Purpose

Enables the counter, controls the counter frequency setting, and controls counter behavior during debug.

### Usage constraints

This register is accessible as follows:

Default

RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

### Configurations

The power domain of CNTCR is IMPLEMENTATION DEFINED.

Some or all fields in this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

### Attributes

CNTCR is a 32-bit register.

### Field descriptions

The CNTCR bit assignments are:

### Bits [31:18]

Reserved, RES0.

### FCREQ, bits [17:8]

Frequency change request. Indicates the number of the entry in the Frequency modes table to select. Selecting an unimplemented entry, or an entry that contains 0, has no effect on the counter.

The maximum number of entries in the Frequency modes table is IMPLEMENTATION DEFINED up to a maximum of 1004 entries, see [The Frequency modes table on page I1-5727](#). An implementation is only required to implement an FCREQ field that can hold values from 0 to the highest supported Frequency modes table entry. Any unrequired most-significant bits of FCREQ can be implemented as RES0.

When this register has an architecturally-defined reset value, this field resets to 0.

### Bits [7:2]

Reserved, RES0.

#### **HDBG, bit [1]**

Halt-on-debug. Controls whether a Halt-on-debug signal halts the system counter:

- 0            System counter ignores Halt-on-debug.
- 1            Asserted Halt-on-debug signal halts system counter update.

This field resets to a value that is architecturally UNKNOWN.

#### **EN, bit [0]**

Enables the counter:

- 0            System counter disabled.
- 1            System counter enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

#### **Accessing the CNTCR:**

CNTCR can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x000

### I3.6.3 CNTCV, Counter Count Value register

The CNTCV characteristics are:

#### Purpose

Indicates the current count value.

#### Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTControlBase	RW
CNTReadBase	RO

A write to CNTCV must be visible in the [CNTPCT](#) register of each running processor in a finite time.

For the instance of the register in the CNTControlBase frame:

- In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, and therefore this register instance, is implemented only in the Secure memory map.
- If the counter is enabled, the effect of writing to the register is UNKNOWN.

In an implementation that supports 64-bit atomic memory accesses, this register must be accessible using a 64-bit atomic access.

#### Configurations

The power domain of CNTCV is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer](#) on page I1-5724.

#### Attributes

CNTCV is a 64-bit register.

#### Field descriptions

The CNTCV bit assignments are:

#### CountValue, bits [63:0]

Indicates the counter value.

### Accessing the CNTCV:

CNTCV[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x008
Timer	CNTReadBase	0x000

CNTCV[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x00C
Timer	CNTReadBase	0x004

### I3.6.4 CNTEL0ACR, Counter-timer EL0 Access Control Register

The CNTEL0ACR characteristics are:

#### Purpose

An implementation of CNTEL0ACR in the frame at CNTBaseN controls whether the [CNTPCT](#), [CNTVCT](#), [CNTFRQ](#), EL1 Physical Timer, and Virtual Timer registers are visible in the frame at CNTEL0BaseN.

#### Usage constraints

CNTEL0ACR can be implemented in any implemented [CNTBaseN](#) frame.

[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733](#) describes the status fields that identify whether a [CNTBaseN](#) frame is implemented, and for an implemented frame:

- Whether the [CNTBaseN](#) frame has virtual timer capability.
- Whether the corresponding [CNTEL0BaseN](#) frame is implemented.
- For an implementation that recognizes two Security states, whether the [CNTBaseN](#) frame, and any corresponding [CNTEL0BaseN](#) frame, is accessible by Non-secure accesses.

If CNTEL0ACR is not implemented in an implemented [CNTBaseN](#) frame:

- The register location in that frame is RAZ/WI.
- If the corresponding [CNTEL0BaseN](#) frame is implemented, the registers [CNTFRQ](#), [CNTP\\_CTL](#), [CNTP\\_CVAL](#), [CNTP\\_TVAL](#), [CNTPCT](#), [CNTV\\_CTL](#), [CNTV\\_CVAL](#), [CNTV\\_TVAL](#), and [CNTVCT](#) are not visible in that frame.

#### Configurations

The power domain of CNTEL0ACR is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

Implementation of this register is OPTIONAL.

#### Attributes

CNTEL0ACR is a 32-bit register.

#### Field descriptions

The CNTEL0ACR bit assignments are:

#### Bits [31:10]

Reserved, RES0.

#### EL0PTEN, bit [9]

Second view read/write access control for the EL1 Physical Timer registers. This bit controls whether the [CNTP\\_CVAL](#), [CNTP\\_TVAL](#), and [CNTP\\_CTL](#) registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

- 0 No access. Registers are RES0 in the second view.
- 1 Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

#### EL0VTEN, bit [8]

Second view read/write access control for the Virtual Timer registers. This bit controls whether the [CNTV\\_CVAL](#), [CNTV\\_TVAL](#), and [CNTV\\_CTL](#) registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

- 0 No access. Registers are RES0 in the second view.
- 1 Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

The definition of this bit means that, if the Virtual Timer registers are not implemented in the current CNTBaseN frame, then the Virtual Timer register addresses are RES0 in the corresponding CNTEL0BaseN frame, regardless of the value of this bit.

#### Bits [7:2]

Reserved, RES0.

#### EL0VCTEN, bit [1]

Second view read access control for [CNTVCT](#) and [CNTFRQ](#). The possible values of this bit are:

- 0 [CNTVCT](#) is not visible in the second view.  
If EL0PCTEN is set to 0, [CNTFRQ](#) is not visible in the second view.
- 1 Access permitted. If [CNTVCT](#) and [CNTFRQ](#) are visible in the current frame then they are visible in the second view.

#### EL0PCTEN, bit [0]

Second view read access control for [CNTPCT](#) and [CNTFRQ](#). The possible values of this bit are:

- 0 [CNTPCT](#) is not visible in the second view.  
If EL0VCTEN is set to 0, [CNTFRQ](#) is not visible in the second view.
- 1 Access permitted. If [CNTPCT](#) and [CNTFRQ](#) are visible in the current frame then they are visible in the second view.

### Accessing the CNTEL0ACR:

CNTEL0ACR can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x014

## I3.6.5 CNTFID0, Counter Frequency ID

The CNTFID0 characteristics are:

### Purpose

Indicates the base frequency of the system counter.

### Usage constraints

This register is accessible as follows:

Default
RO or RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

### Configurations

The power domain of CNTFID0 is IMPLEMENTATION DEFINED.

If this register is implemented as an RW register, on a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0. For more information see [The Frequency modes table on page I1-5727](#).

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

If the Frequency modes table is in read/write memory, ARM strongly recommends that the table is not updated once the system is running.

### Attributes

CNTFID0 is a 32-bit register.

### Field descriptions

The CNTFID0 bit assignments are:

### Frequency, bits [31:0]

The base frequency of the system counter, in Hz.

### Accessing the CNTFID0:

CNTFID0 can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x020

### I3.6.6 CNTFID<n>, Counter Frequency IDs, n > 0

The CNTFID<n> characteristics are:

#### Purpose

Indicates alternative system counter update frequencies.

#### Usage constraints

This register is accessible as follows:

Default
RO or RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes these registers, is implemented only in the Secure memory map.

#### Configurations

The power domain of CNTFID<n> is IMPLEMENTATION DEFINED.

If this register is implemented as an RW register, on a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0, see [The Frequency modes table on page I1-5727](#).

The number of CNTFID<n> registers is IMPLEMENTATION DEFINED, and the only required CNTFID<n> register is CNTFID0.

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

If the Frequency modes table is in read/write memory, ARM strongly recommends that the table is not updated once the system is running.

#### Attributes

CNTFID<n> is a 32-bit register.

#### Field descriptions

The CNTFID<n> bit assignments are:

#### Frequency, bits [31:0]

A system counter update frequency, in Hz. Must be an exact divisor of the base frequency. ARM strongly recommends that all frequency values in the Frequency modes table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

increment = (base frequency) / (selected frequency)

### Accessing the CNTFID<n>:

CNTFID<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x020 + 4n

### I3.6.7 CNTFRQ, Counter-timer Frequency

The CNTFRQ characteristics are:

#### Purpose

This register is provided so that software can discover the frequency of the system counter. The instance of this register in the CNTCTLBase frame must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

#### Usage constraints

CNTFRQ must be implemented as an RW register in the CNTCTLBase frame.

In a system that recognizes two Security states, the instance of this register in the CNTCTLBase frame is only accessible by Secure accesses.

CNTFRQ can be implemented as a RO register in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

*CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733* describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTFRQ is accessible in that frame, as a RO register, if the value of CNTACR<n>.RFRQ is 1.
- Otherwise, the CNTFRQ address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTFRQ is accessible in that frame if both:
  - CNTFRQ is accessible in the corresponding CNTBaseN frame.
  - The value of at least one of CNTEL0ACR.EL0VCTEN and CNTEL0ACR.EL0PCTEN is 1.
- Otherwise, the CNTFRQ address in that frame is RAZ/WI.

#### Configurations

The power domain of CNTFRQ is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

#### Attributes

CNTFRQ is a 32-bit register.

#### Field descriptions

The CNTFRQ bit assignments are:

**Bits [31:0]**

Clock frequency. Indicates the system counter clock frequency, in Hz.

**Accessing the CNTFRQ:**

CNTFRQ can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x010
Timer	CNTELOBaseN	RO	0x010
Timer	CNTCTLBase	RO	0x000

### I3.6.8 CNTNSAR, Counter-timer Non-secure Access Register

The CNTNSAR characteristics are:

#### Purpose

Provides the highest-level control of whether frames CNTBaseN and CNTEL0BaseN are accessible by Non-secure accesses.

#### Usage constraints

This register is accessible as follows:

Default
RW

In a system that recognizes two Security states, this register is only accessible by Secure accesses.

#### Configurations

The power domain of CNTNSAR is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

#### Attributes

CNTNSAR is a 32-bit register.

#### Field descriptions

The CNTNSAR bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### NS<n>, bit [n], for n = 0 to 7

Non-secure access to frame n. The possible values of this bit are:

- 0 Secure access only. Behaves as RES0 to Non-secure accesses.
- 1 Secure and Non-secure accesses permitted.

This bit also determines whether, in the CNTCTLBase frame, [CNTACR<n>](#) and [CNTVOFF<n>](#) are accessible to Non-secure accesses.

If frame CNTBase<n>:

- Is not implemented, then NS<n> is RES0.
- Is not Configurable access, and is accessible only by Secure accesses, then NS<n> is RES0.
- Is not Configurable access, and is accessible by both Secure and Non-secure accesses, then NS<n> is RES1.

### Accessing the CNTNSAR:

CNTNSAR can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x004

### 13.6.9 CNTP\_CTL, Counter-timer Physical Timer Control

The CNTP\_CTL characteristics are:

## Purpose

Control register for the physical timer.

## Usage constraints

CNTP\_CTL can be implemented in any implemented [CNTBaseN](#) frame, and in the corresponding [CNTEL0BaseN](#) frame.

[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page II-5733](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the **CNTBaseN** frame has virtual timer capability.
- Whether the corresponding **CNTEL0BaseN** frame is implemented.
- For an implementation that recognizes two Security states, whether the **CNTBaseN** frame, and any corresponding **CNTEL0BaseN** frame, is accessible by Non-secure accesses.

For an implemented `CNTBaseN` frame:

- CNTP\_CTL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP\_CTL address in that frame is RAZ/WI.

For an implemented **CNTEL0BaseN** frame:

- CNTP\_CTL is accessible in that frame if both:
  - CNTP\_CTL is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.ELOPTEN is 1.
- Otherwise, the CNTP\_CTL address in that frame is RAZ/WI.

## Configurations

The power domain of CNTP\_CTL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I1-5724.

## Attributes

CNTP\_CTL is a 32-bit register.

## Field descriptions

The CNTP\_CTL bit assignments are:

**Bits [31:3]**

Reserved, RES0.

#### ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-2187](#) and [Operation of the TimerValue views of the timers on page D6-2188](#).

This bit is read-only.

#### IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

#### ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTP\\_TVAL](#) continues to count down.

#### Note

Disabling the output signal might be a power-saving option.

### Accessing the CNTP\_CTL:

CNTP\_CTL can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x02C
Timer	CNTELOBaseN	RW	0x02C

### I3.6.10 CNTP\_CVAL, Counter-timer Physical Timer CompareValue

The CNTP\_CVAL characteristics are:

#### Purpose

Holds the 64-bit compare value for the EL1 physical timer.

#### Usage constraints

CNTP\_CVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

*CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733* describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP\_CVAL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP\_CVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTP\_CVAL is accessible in that frame if both:
  - CNTP\_CVAL is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0PTEN is 1.
- Otherwise, the CNTP\_CVAL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTP\_CVAL register must be accessible as an atomic 64-bit value.

#### Configurations

The power domain of CNTP\_CVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

#### Attributes

CNTP\_CVAL is a 64-bit register.

#### Field descriptions

The CNTP\_CVAL bit assignments are:

#### CompareValue, bits [63:0]

Holds the EL1 physical timer CompareValue.

When CNTP\_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTP\_CTL.ISTATUS is set to 1.

- An interrupt is generated if `CNTP_CTL.IMASK` is 0.  
When `CNTP_CTL.ENABLE` is 0, the timer condition is not met, but `CNTPCT` continues to count.

### Accessing the `CNTP_CVAL`:

`CNTP_CVAL[31:0]` can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x020
Timer	CNTELOBaseN	RW	0x020

`CNTP_CVAL[63:32]` can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x024
Timer	CNTELOBaseN	RW	0x024

### I3.6.11 CNTP\_TVAL, Counter-timer Physical Timer TimerValue

The CNTP\_TVAL characteristics are:

#### Purpose

Holds the timer value for the EL1 physical timer.

#### Usage constraints

CNTP\_TVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

*CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733* describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP\_TVAL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP\_TVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTP\_TVAL is accessible in that frame if both:
  - CNTP\_TVAL is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0PTEN is 1.
- Otherwise, the CNTP\_TVAL address in that frame is RAZ/WI.

#### Configurations

The power domain of CNTP\_TVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

#### Attributes

CNTP\_TVAL is a 32-bit register.

#### Field descriptions

The CNTP\_TVAL bit assignments are:

#### TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If CNTP\_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP\_CTL.ENABLE is 1, the value returned is (CompareValue - CNTPCT).

On a write of this register, CompareValue is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When **CNTP\_CTL.ENABLE** is 1, the timer condition is met when (**CNTPCT** - CompareValue) is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- **CNTP\_CTL.ISTATUS** is set to 1.
- If **CNTP\_CTL.IMASK** is 0, an interrupt is generated.

When **CNTP\_CTL.ENABLE** is 0, the timer condition is not met, but **CNTPCT** continues to count, so the TimerValue view appears to continue to count down.

### Accessing the CNTP\_TVAL:

CNTP\_TVAL can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x028
Timer	CNTEL0BaseN	RW	0x028

### I3.6.12 CNTPCT, Counter-timer Physical Count

The CNTPCT characteristics are:

#### Purpose

Holds the 64-bit physical count value.

#### Usage constraints

CNTPCT can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame, as a RO register.

*CNCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733* describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTPCT is accessible in that frame, as a RO register, if the value of CNTACR<n>.RPCT is 1.
- Otherwise, the CNTPCT address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTPCT is accessible in that frame if both:
  - CNTPCT is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0PCTEN is 1.
- Otherwise, the CNTPCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTPCT register must be accessible as an atomic 64-bit value.

#### Configurations

The power domain of CNTPCT is IMPLEMENTATION DEFINED.

For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

#### Attributes

CNTPCT is a 64-bit register.

#### Field descriptions

The CNTPCT bit assignments are:

**Bits [63:0]**

Physical count value.

### Accessing the CNTPCT:

CNTPCT[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RO	0x000
Timer	CNTELOBaseN	RO	0x000

CNTPCT[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RO	0x004
Timer	CNTELOBaseN	RO	0x004

### I3.6.13 CNTSR, Counter Status Register

The CNTSR characteristics are:

#### Purpose

Provides counter frequency status information.

#### Usage constraints

This register is accessible as follows:

Default
RO

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

#### Configurations

The power domain of CNTSR is IMPLEMENTATION DEFINED.

Some or all fields in this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer](#) on page I1-5724.

#### Attributes

CNTSR is a 32-bit register.

#### Field descriptions

The CNTSR bit assignments are:

#### FCACK, bits [31:8]

Frequency change acknowledge. Indicates the currently selected entry in the Frequency modes table, see [The Frequency modes table](#) on page I1-5727.

When this register has an architecturally-defined reset value, this field resets to 0.

#### Bits [7:2]

Reserved, RES0.

#### DBGH, bit [1]

Indicates whether the counter is halted because the Halt-on-Debug signal is asserted:

0 Counter is not halted.

1 Counter is halted.

This field resets to a value that is architecturally UNKNOWN.

**Bit [0]**

Reserved, RES0.

**Accessing the CNTSR:**

CNTSR can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x004

### I3.6.14 CNTTIDR, Counter-timer Timer ID Register

The CNTTIDR characteristics are:

#### Purpose

Indicates the implemented timers in the memory map, and their features. For each value of N from 0 to 7 it indicates whether:

- Frame CNTBaseN is a view of an implemented timer.
- Frame CNTBaseN has a second view, CNTEL0BaseN.
- Frame CNTBaseN has a virtual timer capability.

#### Usage constraints

This register is accessible as follows:

Default
RO

In a system that recognizes two Security states this register is accessible by both Secure and Non-secure accesses.

#### Configurations

The power domain of CNTTIDR is IMPLEMENTATION DEFINED.

For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

#### Attributes

CNTTIDR is a 32-bit register.

#### Field descriptions

The CNTTIDR bit assignments are:

31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0
Frame7	Frame6	Frame5	Frame4	Frame3	Frame2	Frame1	Frame0								

#### Frame<n>, bits [4n+3:4n], for n = 0 to 7

A 4-bit field indicating the features of frame CNTBase<n>.

Bit[3] of the field is RES0.

Bit[2] indicates whether frame CNTBase<n> has a second view, CNTEL0Base<n>. The possible values of this bit are:

Bit[2]	Meaning
0	Frame <n> does not have a second view. CNTEL0Base<n> is RES0.
1	Frame <n> has a second view, CNTEL0Base<n>.

If bit[0] is 0, bit[2] is RES0.

Bit[1] indicates whether both:

- Frame CNTBase<n> implements the virtual timer registers CNTV\_CVAL, CNTV\_TVAL, and CNTV\_CTL.
- This CNTCTLBase frame implements the virtual timer offset register CNTVOFF<n>.

The possible values of bit[1] are:

Bit[1]	Meaning
0	Frame <n> does not have virtual capability. The virtual time and offset registers are RES0.
1	Frame <n> has virtual capability. The virtual time and offset registers are implemented.

If bit[0] is 0, bit[1] is RES0.

Bit[0] indicates whether frame CNTBase<n> is implemented. The possible values of this bit are:

Bit[0]	Meaning
0	Frame <n> not implemented. All registers associated with the frame are RES0.
1	Frame <n> is implemented.

### Accessing the CNTTIDR:

CNTTIDR can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x008

### I3.6.15 CNTV\_CTL, Counter-timer Virtual Timer Control

The CNTV\_CTL characteristics are:

#### Purpose

Control register for the virtual timer.

#### Usage constraints

CNTV\_CTL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

*CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733* describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV\_CTL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV\_CTL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV\_CTL is accessible in that frame if both:
  - CNTV\_CTL is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV\_CTL address in that frame is RAZ/WI.

#### Configurations

The power domain of CNTV\_CTL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

Implementation of this register is OPTIONAL.

#### Attributes

CNTV\_CTL is a 32-bit register.

#### Field descriptions

The CNTV\_CTL bit assignments are:

#### Bits [31:3]

Reserved, RES0.

#### ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-2187](#) and [Operation of the TimerValue views of the timers on page D6-2188](#).

This bit is read-only.

#### IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

#### ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTV\\_TVAL](#) continues to count down.

#### ————— Note —————

Disabling the output signal might be a power-saving option.

### Accessing the CNTV\_CTL:

CNTV\_CTL can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x03C
Timer	CNTELOBaseN	RW	0x03C

### I3.6.16 CNTV\_CVAL, Counter-timer Virtual Timer CompareValue

The CNTV\_CVAL characteristics are:

#### Purpose

Holds the 64-bit compare value for the virtual timer.

#### Usage constraints

CNTV\_CVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

*CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733* describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV\_CVAL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV\_CVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV\_CVAL is accessible in that frame if both:
  - CNTV\_CVAL is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV\_CVAL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTV\_CVAL register must be accessible as an atomic 64-bit value.

#### Configurations

The power domain of CNTV\_CVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

Implementation of this register is OPTIONAL.

#### Attributes

CNTV\_CVAL is a 64-bit register.

#### Field descriptions

The CNTV\_CVAL bit assignments are:

#### CompareValue, bits [63:0]

Holds the virtual timer CompareValue.

When **CNTV\_CTL.ENABLE** is 1, the timer condition is met when (**CNTVCT** - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- **CNTV\_CTL.ISTATUS** is set to 1.
- An interrupt is generated if **CNTV\_CTL.IMASK** is 0.

When **CNTV\_CTL.ENABLE** is 0, the timer condition is not met, but **CNTVCT** continues to count.

### Accessing the CNTV\_CVAL:

CNTV\_CVAL[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x030
Timer	CNTELOBaseN	RW	0x030

CNTV\_CVAL[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x034
Timer	CNTELOBaseN	RW	0x034

### I3.6.17 CNTV\_TVAL, Counter-timer Virtual Timer TimerValue

The CNTV\_TVAL characteristics are:

#### Purpose

Holds the timer value for the virtual timer.

#### Usage constraints

CNTV\_TVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV\_TVAL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV\_TVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV\_TVAL is accessible in that frame if both:
  - CNTV\_TVAL is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV\_TVAL address in that frame is RAZ/WI.

#### Configurations

The power domain of CNTV\_TVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

Implementation of this register is OPTIONAL.

#### Attributes

CNTV\_TVAL is a 32-bit register.

#### Field descriptions

The CNTV\_TVAL bit assignments are:

#### TimerValue, bits [31:0]

The TimerValue view of the virtual timer.

On a read of this register:

- If CNTV\_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV\_CTL.ENABLE is 1, the value returned is (CompareValue - CNTVCT).

On a write of this register, CompareValue is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTV\_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTV\_CTL.ISTATUS is set to 1.
- If CNTV\_CTL.IMASK is 0, an interrupt is generated.

When CNTV\_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down.

### Accessing the CNTV\_TVAL:

CNTV\_TVAL can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x038
Timer	CNTEL0BaseN	RW	0x038

### I3.6.18 CNTVCT, Counter-timer Virtual Count

The CNTVCT characteristics are:

#### Purpose

Holds the 64-bit virtual count value.

#### Usage constraints

CNTVCT can be implemented in any implemented [CNTBaseN](#) frame, and in the corresponding [CNTELOBaseN](#) frame, as a RO register.

[CNTCTLBase status and control fields for the CNTBaseN and CNTELOBaseN frames on page I1-5733](#) describes the status fields that identify whether a [CNTBaseN](#) frame is implemented, and for an implemented frame:

- Whether the [CNTBaseN](#) frame has virtual timer capability.
- Whether the corresponding [CNTELOBaseN](#) frame is implemented.
- For an implementation that recognizes two Security states, whether the [CNTBaseN](#) frame, and any corresponding [CNTELOBaseN](#) frame, is accessible by Non-secure accesses.

For an implemented [CNTBaseN](#) frame:

- CNTVCT is accessible in that frame, as a RO register, if the value of [CNTACR<n>.RVCT](#) is 1.
- Otherwise, the CNTVCT address in that frame is RAZ/WI.

For an implemented [CNTELOBaseN](#) frame:

- CNTVCT is accessible in that frame if both:
  - CNTVCT is accessible in the corresponding [CNTBaseN](#) frame.
  - The value of [CNTELOACR.EL0VCTEN](#) is 1.
- Otherwise, the CNTVCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTVCT register must be accessible as an atomic 64-bit value.

#### Configurations

The power domain of CNTVCT is IMPLEMENTATION DEFINED.

For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

#### Attributes

CNTVCT is a 64-bit register.

#### Field descriptions

The CNTVCT bit assignments are:

Bits [63:0]

Virtual count value.

### Accessing the CNTVCT:

CNTVCT[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RO	0x008
Timer	CNTELOBaseN	RO	0x008

CNTVCT[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RO	0x00C
Timer	CNTELOBaseN	RO	0x00C

### I3.6.19 CNTVOFF{<n>}, Counter-timer Virtual Offset

The CNTVOFF{<n>} characteristics are:

#### Purpose

Holds the 64-bit virtual offset.

#### Usage constraints

In the [CNTCTLBase](#) frame a CNTVOFF{<n>} register must be implemented, as a RW register, for each [CNTBaseN](#) frame that has virtual timer capability.

#### ———— Note ————

The value of <n> in an instance of CNTVOFF{<n>} specifies the value of N for the associated [CNTBaseN](#) frame.

In a system that recognizes two Security states, for any CNTVOFF{<n>} register in the [CNTCTLBase](#) frame:

- CNTVOFF{<n>} is always accessible by Secure accesses.
- [CNTNSAR.NS{<n>}](#) determines whether CNTVOFF{<n>} is accessible by Non-secure accesses.

The register location of any unimplemented CNTVOFF{<n>} register in the [CNTCTLBase](#) frame is RAZ/WI.

CNTVOFF is implemented, as a RO register, in any implemented [CNTBaseN](#) frame that has virtual timer capability.

[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733](#) describes the status fields that identify whether a [CNTBaseN](#) frame is implemented, and for an implemented frame:

- Whether the [CNTBaseN](#) frame has virtual timer capability.
- Whether the corresponding [CNTEL0BaseN](#) frame is implemented.
- For an implementation that recognizes two Security states, whether the [CNTBaseN](#) frame, and any corresponding [CNTEL0BaseN](#) frame, is accessible by Non-secure accesses.

For an implemented [CNTBaseN](#) frame that has virtual timer capability:

- CNTVOFF is accessible in that frame, as a RO register, if the value of [CNTACR{<n>}.RVOFF](#) is 1.
- Otherwise, the CNTVOFF address in that frame is RAZ/WI.

#### ———— Note ————

CNTVOFF is never visible in any [CNTEL0BaseN](#) frame. This means that the CNTVOFF address in any implemented [CNTEL0BaseN](#) frame is RAZ/WI.

In an implementation that supports 64-bit atomic accesses, then the CNTVOFF{<n>} register must be accessible as an atomic 64-bit value.

#### Configurations

The power domain of CNTVOFF is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

Implementation of CNTVOFF{<n>} is OPTIONAL.

[CNTACR{<n>}.RVOFF](#) enables access to this register for frame [CNTBase{<n>}](#).

#### Attributes

CNTVOFF{<n>} is a 64-bit register.

Field descriptions

The CNTVOFF{<n>} bit assignments are:

Bits [63:0]

Virtual offset.

Accessing the CNTVOFF{<n>}:

CNTVOFF{<n>} can be accessed through its memory-mapped interface:

Component	Mnemonic	Frame	Accessibility	Offset
Timer	CNTVOFF<n>[31:0]	CNTCTLBase	RW	0x080 + 8n
Timer	CNTVOFF<n>[64:32]	CNTCTLBase	RW	0x084 + 8n
Timer	CNTVOFF[31:0]	CNTBaseN	RO	0x018
Timer	CNTVOFF[64:32]	CNTBaseN	RO	0x01C

## I3.6.20 CounterID<n>, Counter ID registers, n = 0 - 11

The CounterID<n> characteristics are:

### Purpose

IMPLEMENTATION DEFINED identification registers 0 to 11 for the memory-mapped Generic Timer.

### Usage constraints

These registers must be implemented, as RO registers, in every implemented frame of a Generic Timer memory-mapped component.

For the CNTCTLBase frame, in a system that recognizes two Security states these registers are accessible by both Secure and Non-secure accesses.

For the CNTControlBase frame, in a system that supports Secure and Non-secure memory maps the frame is implemented only in the Secure memory map, meaning these registers are implemented only in the Secure memory map.

For the CNTBaseN frames, [CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733](#) describes the status fields that identify whether a frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

### Configurations

The power domain of CounterID<n> is IMPLEMENTATION DEFINED.

For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

These registers are implemented independently in each implemented frame of a Generic Timer memory-mapped component.

If the implementation of the Counter ID registers requires an architecture version, the value for this version of the ARM Generic Timer is version 0.

The Counter ID registers can be implemented as a set of CoreSight ID registers, comprising Peripheral ID Registers and Component ID Registers. An implementation of these registers for the Generic Timer must use a Component class value of 0xF.

### Attributes

CounterID<n> is a 32-bit register.

### Field descriptions

The CounterID<n> bit assignments are:

### IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

### Accessing the CounterID<n>:

CounterID<n> can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTControlBase	RO	0xFD0 + 4n
Timer	CNTReadBase	RO	0xFD0 + 4n
Timer	CNTBaseN	RO	0xFD0 + 4n
Timer	CNTEL0BaseN	RO	0xFD0 + 4n
Timer	CNTCTLBase	RO	0xFD0 + 4n

# Part J

## **Architectural Pseudocode**

# Chapter J1

## ARMv8 Pseudocode

This chapter contains pseudocode that describes many features of the ARMv8 architecture. It contains the following sections:

- *Pseudocode for AArch64 operations on page J1-5860.*
- *Pseudocode for AArch32 operation on page J1-5930.*
- *Shared pseudocode on page J1-6006.*

## J1.1 Pseudocode for AArch64 operations

This section holds the pseudocode for execution in AArch64 state. Functions that are listed in this section are identified as AArch64.FunctionName. Some of these functions have an equivalent AArch32 function, AArch32.FunctionName. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example aarch64/debug/breakpoint.

The top-level sections of the AArch64 pseudocode hierarchy are:

- [aarch64/debug](#).
- [aarch64/exceptions](#) on page J1-5869.
- [aarch64/functions](#) on page J1-5887.
- [aarch64/instrs](#) on page J1-5903.
- [aarch64/translation](#) on page J1-5911.

### J1.1.1 aarch64/debug

This section includes the following pseudocode functions:

- [aarch64/debug/breakpoint/AArch64.BreakpointMatch](#).
- [aarch64/debug/breakpoint/AArch64.BreakpointValueMatch](#) on page J1-5861.
- [aarch64/debug/breakpoint/AArch64.StateMatch](#) on page J1-5862.
- [aarch64/debug/enables/AArch64.GenerateDebugExceptions](#) on page J1-5863.
- [aarch64/debug/enables/AArch64.GenerateDebugExceptionsFrom](#) on page J1-5863.
- [aarch64/debug/pmu/AArch64.CheckForPMUOverflow](#) on page J1-5864.
- [aarch64/debug/pmu/AArch64.CountEvents](#) on page J1-5864.
- [aarch64/debug/statisticalprofiling/CheckProfilingBufferAccess](#) on page J1-5865.
- [aarch64/debug/statisticalprofiling/CheckStatisticalProfilingAccess](#) on page J1-5865.
- [aarch64/debug/statisticalprofiling/CollectContextIDR1](#) on page J1-5866.
- [aarch64/debug/statisticalprofiling/CollectContextIDR2](#) on page J1-5866.
- [aarch64/debug/statisticalprofiling/CollectPhysicalAddress](#) on page J1-5866.
- [aarch64/debug/statisticalprofiling/CollectRecord](#) on page J1-5866.
- [aarch64/debug/statisticalprofiling/CollectTimeStamp](#) on page J1-5867.
- [aarch64/debug/statisticalprofiling/OpType](#) on page J1-5867.
- [aarch64/debug/statisticalprofiling/ProfilingBufferEnabled](#) on page J1-5867.
- [aarch64/debug/statisticalprofiling/ProfilingBufferOwner](#) on page J1-5867.
- [aarch64/debug/statisticalprofiling/ProfilingSynchronizationBarrier](#) on page J1-5867.
- [aarch64/debug/statisticalprofiling/StatisticalProfilingEnabled](#) on page J1-5867.
- [aarch64/debug/statisticalprofiling/SysRegAccess](#) on page J1-5868.
- [aarch64/debug/takeexceptiondbg/AArch64.TakeExceptionInDebugState](#) on page J1-5868.
- [aarch64/debug/watchpoint/AArch64.WatchpointByteMatch](#) on page J1-5868.
- [aarch64/debug/watchpoint/AArch64.WatchpointMatch](#) on page J1-5869.

#### aarch64/debug/breakpoint/AArch64.BreakpointMatch

```
// AArch64.BreakpointMatch()
// =====
// Breakpoint matching in an AArch64 translation regime.

boolean AArch64.BreakpointMatch(integer n, bits(64) vaddress, integer size)
    assert !ELUsingAArch32(S1TranslationRegime());
    assert n <= UInt(ID_AA64DFR0_EL1.BRPs);

    enabled = DBGBCR_EL1[n].E == '1';
    ispriv = PSTATE.EL != EL0;
    linked = DBGBCR_EL1[n].BT == '0x01';
    isbreakpt = TRUE;
    linked_to = FALSE;
```

```

## J1.2 Pseudocode for AArch32 operation

This section holds the pseudocode for execution in AArch32 state. Functions that are listed in this section are identified as AArch32.FunctionName. Some of these functions have an equivalent AArch64 function, AArch64.FunctionName. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example aarch32/debug/breakpoint.

### ———— Note ————

Many AArch32 pseudocode functions have not been updated to show the constraints on the ARMv7 UNPREDICTABLE behaviors that are described in [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#). Where AArch32 pseudocode shows something to be UNPREDICTABLE, check [Appendix K1](#) for possible constraints on the permitted behavior.

The top-level sections of the AArch32 pseudocode hierarchy are:

- [aarch32/debug](#).
- [aarch32/exceptions](#) on page J1-5938.
- [aarch32/functions](#) on page J1-5956.
- [aarch32/translation](#) on page J1-5985.

### J1.2.1 aarch32/debug

This section includes the following pseudocode functions:

- [aarch32/debug/VCRMatch/AArch32.VCRMatch](#).
- [aarch32/debug/authentication/AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled](#) on page J1-5931.
- [aarch32/debug/breakpoint/AArch32.BreakpointMatch](#) on page J1-5931.
- [aarch32/debug/breakpoint/AArch32.BreakpointValueMatch](#) on page J1-5932.
- [aarch32/debug/breakpoint/AArch32.StateMatch](#) on page J1-5933.
- [aarch32/debug/enables/AArch32.GenerateDebugExceptions](#) on page J1-5934.
- [aarch32/debug/enables/AArch32.GenerateDebugExceptionsFrom](#) on page J1-5934.
- [aarch32/debug/pmu/AArch32.CheckForPMUOverflow](#) on page J1-5935.
- [aarch32/debug/pmu/AArch32.CountEvents](#) on page J1-5935.
- [aarch32/debug/takeexceptiondbg/AArch32.EnterHypModeInDebugState](#) on page J1-5936.
- [aarch32/debug/takeexceptiondbg/AArch32.EnterModeInDebugState](#) on page J1-5936.
- [aarch32/debug/takeexceptiondbg/AArch32.EnterMonitorModeInDebugState](#) on page J1-5937.
- [aarch32/debug/watchpoint/AArch32.WatchpointByteMatch](#) on page J1-5937.
- [aarch32/debug/watchpoint/AArch32.WatchpointMatch](#) on page J1-5938.

## J1.3 Shared pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a FunctionName, without an AArch64. or AArch32. prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `shared/debug/DebugTarget`.

---

### ———— Note —————

Currently, the following pseudocode functions in this group reference C program functions, that are not linked from the pseudocode, to describe their operation:

`UnsignedRecipEstimate()`

Calls the C function `recip_estimate()`. This function is defined in *Floating-point reciprocal estimate and step* on page E1-2749.

`UnsignedRSqrtEstimate()`

Calls the C function `recip_sqrt_estimate()`. This function is defined in *Floating-point reciprocal square root estimate and step* on page E1-2750.

---

The top-level sections of the shared pseudocode hierarchy are:

- *shared/debug*.
- *shared/exceptions* on page J1-6024.
- *shared/functions* on page J1-6026.
- *shared/translation* on page J1-6086.

### J1.3.1 shared/debug

This section includes the following pseudocode functions:

- *shared/debug/ClearStickyErrors/ClearStickyErrors* on page J1-6007.
- *shared/debug/DebugTarget/DebugTarget* on page J1-6007.
- *shared/debug/DebugTarget/DebugTargetFrom* on page J1-6008.
- *shared/debug/DoubleLockStatus/DoubleLockStatus* on page J1-6008.

## Architectural Constraints on UNPREDICTABLE behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the ARMv8 architecture. It contains the following sections:

- [AArch32 CONSTRAINED UNPREDICTABLE behaviors on page K1-6096.](#)
- [AArch64 CONSTRAINED UNPREDICTABLE behaviors on page K1-6119.](#)

## K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

ARMv8 defines architecturally-required constraints on many behaviors that are UNPREDICTABLE in ARMv7. The following sections define those constraints:

- [Overview of the constraints on ARMv7 UNPREDICTABLE behaviors on page K1-6097.](#)
- [Using R13 on page K1-6097.](#)
- [Using R15 on page K1-6097.](#)
- [Branching into an IT block on page K1-6098.](#)
- [Branching to an unaligned PC on page K1-6098.](#)
- [Loads and Stores to unaligned locations on page K1-6098.](#)
- [CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT on page K1-6098.](#)
- [Unallocated System register access instructions on page K1-6100.](#)
- [SBZ or SBO fields T32 and A32 in instructions on page K1-6100.](#)
- [UNPREDICTABLE cases in immediate constants in T32 data-processing instructions on page K1-6100.](#)
- [UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions on page K1-6101.](#)
- [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101.](#)
- [CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-6102.](#)
- [Translation Table Base Address alignment on page K1-6102.](#)
- [Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-6102.](#)
- [The Performance Monitors Extension on page K1-6103.](#)
- [Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page K1-6104.](#)

- [CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-6118.](#)

### K1.1.1 Overview of the constraints on ARMv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

---

#### Note

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases.

---

### K1.1.2 Using R13

In prior versions of the architecture, the use of R13 as a named register specifier was described as UNPREDICTABLE in the pseudocode. In the ARMv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, unless this is specifically stated, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as RES0, but can hold any values programmed into them.

### K1.1.3 Using R15

All uses of R15 as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this Manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Read or return an UNKNOWN value for the source register specified as R15.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Ignore the write.
- Branch to an UNKNOWN location in either A32 or T32 state.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example LDRD, MRRC, and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN, if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of [PSTATE](#).{N, Z, C, V}, [PSTATE](#).Q, and [PSTATE](#).GE when the register specifier is not R15, any flags affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier is R15 become UNKNOWN,

In addition, for MRC instructions that use R15 as the destination register descriptor, and therefore target APSR\_nzcv where these are described as being CONSTRAINED UNPREDICTABLE, [PSTATE](#).{N, Z, C, V} becomes UNKNOWN.

#### K1.1.4 Branching into an IT block

Branching into an IT block leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its [Condition code check](#) within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed the [Condition code check](#).

#### K1.1.5 Branching to an unaligned PC

In A32 state, when branching to an address that is not word aligned and is defined to be CONSTRAINED UNPREDICTABLE, one of the following behaviors must occur:

- The unaligned location is forced to be aligned.
- The unaligned address generates an exception on the first instruction using the unaligned PC value. If that instruction is executed at EL0 and either of the following applies, the exception is taken to EL2:
  - EL2 is using AArch32 and the value of [HCR.TGE](#) is 1
  - EL2 is using AArch64 and the value of [HCR\\_EL2.TGE](#) is 1.

If the instruction is executed at EL0 when the applicable TGE bit is 0 the exception is taken to EL1.

If the instruction is executed at an Exception level that is higher than EL0 the exception is taken to the Exception level at which the instruction was executed.

In all cases, the exception is generated only if the first instruction using the unaligned PC value is architecturally executed.

If the exception that results from a branch to an unaligned PC value:

- Is taken to an Exception level that is using AArch64, it is reported as a PC alignment fault exception, see [Exception from an Illegal Execution state, PC alignment fault, or SP alignment fault on page D1-1808](#).
- Is taken to an Exception level that is using AArch32, it is reported as a Prefetch Abort exception, see [Prefetch Abort exception reporting a PC alignment fault exception on page G1-4385](#).

##### ———— Note ————

Because bit[0] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of [IFAR](#), [HIFAR](#), or [FAR\\_ELx](#) is 0 for all these cases.

#### K1.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the ARMv7 architecture are described as UNPREDICTABLE. These are defined in the ARMv8-A architecture to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

#### K1.1.7 CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
- The instructions are executed as if they had passed the [Condition code check](#).
- The instructions execute as NOPs. This means that they behave as if they had failed the [Condition code check](#).

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the `PSTATE.IT` state machine must be treated in one of the following ways:

- `PSTATE.IT` is cleared to 0.
- `PSTATE.IT` advances for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

---

**Note**

This does not apply to an instruction that is the last instruction in an IT block.

---

The instructions addressed by the updated PC must do one of the following:

- Execute as if they had passed the [Condition code check](#) for the remaining iterations of the `PSTATE.IT` state machine.
- Execute as NOPs. That is, they behave as if they had failed the [Condition code check](#) for the remaining iterations of the `PSTATE.IT` state machine.
- Execute as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior described in [Branching into an IT block on page K1-6098](#).

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause `PSTATE.IT` to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in `PSTATE.IT`, the `PSTATE.IT` bits are forced to '00000000'. The reserved values are:

$$\begin{aligned} \text{PSTATE.IT}[7:4] & \neq \text{'0000'} \ \&\& \ \text{PSTATE.IT}[3:0] = \text{'0000'} \\ \text{PSTATE.IT}[2:0] & \neq \text{'000'} \ \text{when} \ \text{SCTLR/SCTLR\_EL\_1.ITD} == \text{'1'} \end{aligned}$$

Exception returns or Debug state exits that set `PSTATE.IT` to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

- Outside an IT block, but with the `PSTATE.IT` bits set to a value other than '00000000'.
- Inside an IT block, but with a different value of the `PSTATE.IT` bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit must do one of the following:

- Execute as if they passed the [Condition code check](#) for the remaining iterations of the `PSTATE.IT` state machine.
- Execute as NOPs. That is, they behave as if they failed the [Condition code check](#) for the remaining iterations of the `PSTATE.IT` state machine.
- Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in [Branching into an IT block on page K1-6098](#).

The remaining iterations of the `PSTATE.IT` state machine must behave in one of the following ways:

- The `PSTATE.IT` state machine advances as if it were in an IT block.
- The `PSTATE.IT` bits are ignored.
- The `PSTATE.IT` bits are forced to '00000000'.

## K1.1.8 Unallocated System register access instructions

In ARMv8-A, accesses to unallocated System register encodings are UNDEFINED.

This includes:

- Reads using encodings that are defined as WO.
- Writes using encodings that are defined as RO.
- MCR or MRC accesses to using a set of {coproc, CRn, opc1, CRm, opc2} values that the ARMv7 architecture defined as UNPREDICTABLE.
- Accesses to System registers in the (coproc==0b111x) encoding space that the ARMv7 architecture defined as UNPREDICTABLE when particular functionality was not implemented, when an ARMv8 implementation does not include the Exception level that provides that functionality.

## K1.1.9 SBZ or SBO fields T32 and A32 in instructions

Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO. If the instruction bit pattern of an instruction is executed with these fields not having the *should-be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:

- [LDM, LDMIA, LDMFD on page F5-3144](#).
- [LDMDB, LDMEA on page F5-3154](#).
- [LDR \(literal\) on page F5-3163](#).
- [LDRB \(literal\) on page F5-3172](#).
- [LDRD \(immediate\) on page F5-3180](#).
- [LDRD \(register\) on page F5-3186](#).
- [LDRD \(literal\) on page F5-3183](#).
- [LDRH \(literal\) on page F5-3200](#).
- [LDRSB \(literal\) on page F5-3211](#).
- [LDRSH \(literal\) on page F5-3222](#).
- [POP on page F5-3325](#).
- [PUSH on page F5-3331](#).
- [SDIV on page F5-3407](#).
- [STM, STMIA, STMEA on page F5-3495](#).
- [STMDB, STMFD on page F5-3503](#).
- [UDIV on page F5-3610](#).

## K1.1.10 UNPREDICTABLE cases in immediate constants in T32 data-processing instructions

The description of immediate constants in T32 data processing [Modified immediate constants in T32 instructions on page F2-2863](#) include constant values that were UNPREDICTABLE in ARMv7. [Instruction encodings on page F2-2844](#) describes 32-bit T32 instructions as {hw1, hw2}, where hw1 is the left-hand halfword in the 32-bit encoding diagram for the instruction. The UNPREDICTABLE cases are those where both:

- hw2[7:0] == 0b0000000.
- hw1[10] == 0 and either:
  - hw2[14:12] == 0b001.
  - hw2[14:12] == 0b010.
  - hw2[14:12] == 0b011.

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce the value 0b0000000.

### K1.1.11 UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions

The description of immediate constants in [Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2865](#) include constant values that were UNPREDICTABLE in ARMv7. The UNPREDICTABLE cases are those where:

- The bits that the encoding diagram shows as abcd are all 0.  
In the A32 encoding these are bits[24, 18:6, 3:0]. In the T32 encoding they are bits {hw1[12, 2:0], hw2[3:0]}.
  - The bits that the encoding diagram shows as cmode[3:1] are one of {0b001, 0b010, 0b011, 0b101, 0b110}.
- In the A32 encoding these are bits[11:9]. In the T32 encoding they are bits hw2[11:9].

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce an immediate constant value of zero.

### K1.1.12 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to CONSTRAINED UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes ARMv8.2-TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

#### ————— Note —————

If the effective control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that effective value must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits within a TLB might generate an exception, reporting the exception using the TLB Conflict fault code, see [TLB conflict aborts on page G4-4630](#).

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

### K1.1.13 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to CONSTRAINED UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

### K1.1.14 Translation Table Base Address alignment

A misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and [TTBR0](#)[13:N:7], which is defined to be RES0, contains one or more nonzero values.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and [TTBR0](#)[x-1:3], [TTBR1](#)[x-1:3], [HTTBR](#)[x-1:3], or [VTTBR](#)[x-1:3], which are defined to be RES0, contain one or more nonzero values.

In the event of a misaligned Translation Table Base Address, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all bits were zero:
  - The value that is read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using that register might be corrupted in those bits that are nonzero.

### K1.1.15 Handling of System register control fields for Advanced SIMD and floating-point operation

For historical reasons described in [Background to the System register interface on page G1-4410](#), each of the [CPACR](#), [HCPTR](#), and [NSACR](#) has a pair of control fields that were defined to have identical functionality for controlling Advanced SIMD and floating-point operation. These fields are:

- [CPACR](#).{cp10, cp11}.
- [HCPTR](#).{TCP10, TCP11}.
- [NSACR](#).{cp10, cp11}.

The architecture requires that both fields in one of these pairs are programmed to the same value. If this is not done, then the CONSTRAINED UNPREDICTABLE behavior is that behavior is the same as if the cp11, or TCP11, control field was equal to the cp10, or TCP10, field in all respects other than the value read back by a direct read of the register. After a register write that writes different values to the two fields of a pair, a direct read of the register might return an UNKNOWN value for the cp11 or TCP11 field.

#### ————— **Note** —————

This means that, when different values are written to the {cp10, cp11} fields in a single register, the architecture permits but does not require that a read of that register returns the value written to the cp11 field.

## CONSTRAINED UNPREDICTABLE CPACR and NSACR settings

If [CPACR](#).cp<n> contains the encoding '10', then one of the following behaviors must occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.

---

### Note

In ARMv7, [CPACR](#) had a D32DIS bit, and [NSACR](#) had an NSD32DIS bit. There is no [CPACR](#).D32DIS or [NSACR](#).NSD32DIS in ARMv8-A, and the corresponding bits in the two registers are RES0.

---

## K1.1.16 The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch32 state:

- [CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXVCNTR](#).
- [CONSTRAINED UNPREDICTABLE accesses to PMXVCNTR<n> and PMXEVTYPER<n> on page K1-6104](#).
- [CONSTRAINED UNPREDICTABLE behavior caused by HDCR.HPMN on page K1-6104](#).

## CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXVCNTR

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If [PMSELR](#).SEL is not equal to 31, and [PMSELR](#).SEL is greater than or equal to [PMCR](#).N, and the PE is executing in Secure state or in Non-secure Hyp mode.
- If [PMSELR](#).SEL is not 31, and [PMSELR](#).SEL is greater than or equal to [HDCR](#).HPMN, and the PE is executing in a Non-secure mode other than Hyp mode.

In these UNPREDICTABLE cases, one of the following behaviors must occur:

- Accesses to [PMXEVTYPER](#) or [PMXVCNTR](#) from that mode are UNDEFINED.
- Accesses to [PMXEVTYPER](#) or [PMXVCNTR](#) from that mode behave as RAZ/WI.
- Accesses to [PMXEVTYPER](#) or [PMXVCNTR](#) from that mode execute as NOPs.
- Accesses to [PMXEVTYPER](#) or [PMXVCNTR](#) from that mode behave as if [PMSELR](#).SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to [PMXEVTYPER](#) or [PMXVCNTR](#) behave as if [PMSELR](#).SEL is 31.
- In Non-secure state, for an access to [PMXEVTYPER](#) or [PMXVCNTR](#) from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of [PMUSERENR](#).EN is 1.
  - EL1 is using AArch64 and the value of [PMUSERENR](#).\_EL0.EN is 1.

If [PMSELR](#).SEL is equal to 31, then one of the following behaviors must occur:

- Accesses to [PMXVCNTR](#) are UNDEFINED.
- Accesses to [PMXVCNTR](#) behave as RAZ/WI.
- Accesses to [PMXVCNTR](#) execute as NOPs.
- Accesses to [PMXVCNTR](#) behave as if [PMSELR](#).SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.

- In Non-secure state, for an access to [PMXEVCNTR](#) from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of [PMUSERENR.EN](#) is 1.
  - EL1 is using AArch64 and the value of [PMUSERENR\\_EL0.EN](#) is 1.

---

**Note**

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, [HDCR.HPMN](#), or [MDCR\\_EL2.HPMN](#), identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

---

### CONSTRAINED UNPREDICTABLE accesses to [PMEVCNTR<n>](#) and [PMEVTYPER<n>](#)

If [<n>](#) is greater than the number of counters available in the current Exception level and state, reads and writes of [PMEVCNTR<n>](#) and [PMEVTYPER<n>](#) are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- In Non-secure state, for an access to [PMEVCNTR<n>](#) or [PMEVTYPER<n>](#) from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of [PMUSERENR.EN](#) is 1.
  - EL1 is using AArch64 and the value of [PMUSERENR\\_EL0.EN](#) is 1.

---

**Note**

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, [HDCR.HPMN](#), or [MDCR\\_EL2.HPMN](#), identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

---

### CONSTRAINED UNPREDICTABLE behavior caused by [HDCR.HPMN](#)

If [HDCR.HPMN](#) is set to 0 or to a value greater than [PMCR.N](#), then the CONSTRAINED UNPREDICTABLE behavior is:

- The value returned by a direct read of [HDCR.HPMN](#) is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if [HDCR.HPMN](#) is set to an UNKNOWN non-zero value less than [PMCR.N](#).
  - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

#### K1.1.17 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, this generates an exception:

- If this exception is taken to an Exception level that is using AArch64 then [ESR\\_ELx](#) is UNKNOWN.
- If this exception is taken to EL2 and EL2 is using AArch32, then the [HSR](#) is UNKNOWN.

---

**Note**

The value written to ESR or HSR must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but resulted from a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

---

### K1.1.18 Out of range virtual address

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.

### K1.1.19 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location when address translation is enabled.

If a branch causes the program counter to point to a location in memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

### K1.1.20 Multi-access instructions that load the PC from Device memory

Multi-access instructions that load the PC from Device memory when address translation is enabled are UNPREDICTABLE in AArch32 state. In the ARMv8-A architecture in AArch32 state an implementation must perform one of the following behaviors:

- It loads the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It generates a permission fault.

### K1.1.21 Programming CSSELR.Level for a cache level that is not implemented

If CSSELR.Level is programmed to a cache level that is not implemented, then a read of CSSELR returns an UNKNOWN value in CSSELR.Level.

If the CSSELR.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR an implementation must perform one of the following behaviors:

- The CCSIDR read executes as a NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

### K1.1.22 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.

- The instruction generates an alignment fault caused by the memory type.  
For the Non-secure PL1&0 translation regime:
  - If the stage 1 translation causes the mismatch then the resulting exception is taken to PL1.
  - If the stage 2 translation causes the mismatch then the resulting exception is taken to PL2.
  - If both stages of translation cause the mismatch then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a NOP.

### K1.1.23 Crossing a 4KB boundary with a Device access

A memory access from a load or store instruction to Device memory that crosses a 4KB boundary results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault caused by the memory type.  
For the Non-secure PL1&0 translation regime:
  - If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to PL1.
  - If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to PL2.
  - If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a NOP.

———— **Note** ————

The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.

### K1.1.24 UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

*Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-2802* defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. These cases were UNPREDICTABLE in ARMv7. In summary, these cases are:

- The target virtual address of a StoreExcl instruction is different from the virtual address of the preceding LoadExcl instruction in the same thread of execution.
- The transaction size of a StoreExcl instruction is different from the transaction size of the preceding LoadExcl instruction in the same thread of execution.
- The memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, either:
  - Because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction.
  - Because the LoadExcl instruction and the StoreExcl instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in [Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-2802](#) for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

---

**Note**

Additional CONSTRAINED UNPREDICTABLE cases can apply to Load-Exclusive and Store-Exclusive instructions, see [CONSTRAINED UNPREDICTABLE behavior for A32 and T32 system instructions in the base instruction set on page K1-6108](#).

---

## K1.1.25 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings

The A32 and T32 instruction sets include encodings that result in CONSTRAINED UNPREDICTABLE behavior when they are decoded.

### CONSTRAINED UNPREDICTABLE behavior of CRC32 instruction encodings

In the A32 and T32 instruction sets, there are encodings of the [CRC32](#) and [CRC32C](#) instructions that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in the following places in the A32 and T32 instruction sets:

- [Cyclic Redundancy Check on page F4-2952](#) for the A32 instruction set, with sz = 11.
- [Data-processing \(two source registers\) on page F3-2937](#) for the T32 instruction set, with op1 = 10x and op2 = 11.

The CONSTRAINED UNPREDICTABLE behavior for these encodings is described in [CRC32 on page F5-3094](#) and [CRC32C on page F5-3097](#).

### CONSTRAINED UNPREDICTABLE behavior of other A32 instruction encodings

In the A32 instruction set, there are encodings that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in:

- [Miscellaneous on page F4-2984](#).
- [Memory hints and barriers on page F4-2995](#).
- [Barriers on page F4-2996](#).

The CONSTRAINED UNPREDICTABLE behavior is that an implementation must treat the encodings in one of the following ways:

- The instruction encoding is UNDEFINED.
- The instruction encoding executes as NOP.

## K1.1.26 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions [DCCISW](#), [DCCSW](#), and [DCISW](#), if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

---

**Note**

---

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the A64 cache maintenance by set/way instructions [DC C1SW](#), [DC CSW](#), and [DC ISW](#).

---

### K1.1.27 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 system instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 system instructions.

---

**Note**

---

If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

---

#### SRS (T32)

For a description of this instruction and the encoding, see [SRS](#), [SRSDA](#), [SRSDDB](#), [SRSIA](#), [SRSIB](#) on page F5-3464.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

#### SRS (A32)

For a description of this instruction and the encoding, see [SRS](#), [SRSDA](#), [SRSDDB](#), [SRSIA](#), [SRSIB](#) on page F5-3464.

#### **CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

## SUBS PC, LR and related instructions (T32)

For a description of this instruction and the encoding, see the exception return form of *SUB, SUBS (immediate)* on page F5-3560.

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to *PSTATE.M*, then this invokes the illegal exception return.

#### Note

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

For this encoding:

- If *hw2[3:0]* are 0b1110, and the instruction is executed when not in Hyp mode, System mode, or User mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if *hw2[3:0]* are 0b1110.
  - The program counter is set using the value in the register specified by *hw2[3:0]*.

## SUBS PC, LR and related instructions (A32)

For a description of this instruction and the encoding, see the exception return forms of *MOV, MOVS (register)* on page F5-3260 and *SUB, SUBS (immediate)* on page F5-3560.

### CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to *PSTATE.M*, then this invokes the illegal exception return.

#### Note

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

## K1.1.28 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 Advanced SIMD and floating-point instructions listed in [Alphabetical list of floating-point and Advanced SIMD instructions on page F6-3680](#).

### ———— Note ————

- The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

### VCVT (between floating-point and fixed-point)

For a description of this instruction and the encoding, see [VCVT \(between floating-point and fixed-point, floating-point\) on page F6-3819](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VLD1 (multiple single elements)

For a description of this instruction and the encoding, see [VLD1 \(multiple single elements\) on page F6-3889](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VLD1 (single element to all lanes)

For a description of this instruction and the encoding, see [VLD1 \(single element to all lanes\) on page F6-3886](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VLD2 (multiple 2-element structures)

For a description of this instruction and the encoding, see [VLD2 \(multiple 2-element structures\) on page F6-3906](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### VLD2 (single 2-element structure to one lane)

For a description of this instruction and the encoding, see [VLD2 \(single 2-element structure to one lane\) on page F6-3897](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD2 (single 2-element structure to all lanes)**

For a description of this instruction and the encoding, see [VLD2 \(single 2-element structure to all lanes\)](#) on page F6-3903.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD3 (multiple 3-element structures)**

For a description of this instruction and the encoding, see [VLD3 \(multiple 3-element structures\)](#) on page F6-3920.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD3 (single 3-element structure to one lane)**

For a description of this instruction and the encoding, see [VLD3 \(single 3-element structure to one lane\)](#) on page F6-3911.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD3 (single 3-element structure to all lanes)**

For a description of this instruction and the encoding, see [VLD3 \(single 3-element structure to all lanes\)](#) on page F6-3917.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD4 (multiple 4-element structures)**

For a description of this instruction and the encoding, see [VLD4 \(multiple 4-element structures\)](#) on page F6-3932.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VLD4 (single 4-element structure to one lane)**

For a description of this instruction and the encoding, see [VLD4 \(single 4-element structure to one lane\)](#) on page F6-3923.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

#### **VLD4 (single 4-element structure to all lanes)**

For a description of this instruction and the encoding, see [VLD4 \(single 4-element structure to all lanes\)](#) on page F6-3929.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

#### **VLDM**

For a description of this instruction and the encoding, see [VLDM, VLDMDB, VLDMIA](#) on page F6-3935.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

#### **VMOV (between two general-purpose registers and two single-precision registers)**

For a description of this instruction and the encoding, see [VMOV \(between two general-purpose registers and two single-precision registers\)](#) on page F6-4008.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

#### **VMOV (between two general-purpose registers and a doubleword floating-point register)**

For a description of this instruction and the encoding, see [VMOV \(between two general-purpose registers and a doubleword floating-point register\)](#) on page F6-3988.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

#### **VST1 (multiple single elements)**

For a description of this instruction and the encoding, see [VST1 \(multiple single elements\)](#) on page F6-4231.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

#### **VST2 (multiple 2-element structures)**

For a description of this instruction and the encoding, see [VST2 \(multiple 2-element structures\)](#) on page F6-4245.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VST2 (single 2-element structure from one lane)**

For a description of this instruction and the encoding, see [VST2 \(single 2-element structure from one lane\)](#) on page F6-4239.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VST3 (multiple 3-element structures)**

For a description of this instruction and the encoding, see [VST3 \(multiple 3-element structures\)](#) on page F6-4256.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VST3 (single 3-element structure from one lane)**

For a description of this instruction and the encoding, see [VST3 \(single 3-element structure from one lane\)](#) on page F6-4250.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VST4 (multiple 4-element structures)**

For a description of this instruction and the encoding, see [VST4 \(multiple 4-element structures\)](#) on page F6-4265.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VST4 (single 4-element structure from one lane)**

For a description of this instruction and the encoding, see [VST4 \(single 4-element structure from one lane\)](#) on page F6-4259.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

### **VSTM**

For a description of this instruction and the encoding, see [VSTM, VSTMDB, VSTMIA](#) on page F6-4268.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

## K1.1.29 CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR

The following subsections describe the CONSTRAINED UNPREDICTABLE behavior associated with programming the VTCR:

- [Misprogramming VTCR.S](#).
- [Misprogramming VTCR.{SL0, T0SZ}](#).

### Misprogramming VTCR.S

VTCR.S must be programmed to the value of T0SZ[3], or the effect is CONSTRAINED UNPREDICTABLE. For the ARMv8-A architecture, if VTCR.S is not programmed correctly, then the VTCR.T0SZ value is treated as an UNKNOWN value.

#### ———— Note ————

The CONSTRAINED UNPREDICTABLE behavior described in [Misprogramming VTCR.{SL0, T0SZ}](#) means the UNKNOWN VTCR.T0SZ value might generate a Translation fault.

### Misprogramming VTCR.{SL0, T0SZ}

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR.SL0 field, or the VTCR.SL0 field is programmed to a reserved value, then at the time of a translation walk that uses the stage 2 translation, a stage 2 level 1 Translation Fault is generated.

## K1.1.30 CONSTRAINED UNPREDICTABLE behavior of EL2 features

The following sections describe CONSTRAINED UNPREDICTABLE behavior that can occur in an implementation that includes EL2 where EL2 can use AArch32:

- [ERET in User mode or System mode](#).
- [Accessing Hyp mode from outside Hyp mode](#).
- [Modifying PSTATE.M when in Hyp mode on page K1-6115](#).
- [Use of Hyp mode in Secure state on page K1-6115](#).
- [Execution of Load/Store unprivileged instructions in Hyp mode on page K1-6115](#).
- [Exception return to Hyp mode on page K1-6115](#).
- [Accessing registers that cannot be accessed using MSR/MRS instructions on page K1-6115](#).
- [Memory type handling on page K1-6116](#).
- [Hyp mode TLB maintenance instructions on page K1-6116](#).
- [Hyp mode VA to PA address translation instructions on page K1-6116](#).
- [Stage 1 default memory type on page K1-6116](#).
- [Trapping of general exceptions to Hyp mode on page K1-6116](#).
- [Prevention of rootkits using Hyp mode or Secure state on page K1-6117](#).
- [HVC on page K1-6117](#).
- [MSR/MRS Banked registers on page K1-6117](#).

### ERET in User mode or System mode

If ERET is executed in User mode or System mode, it behaves as described in [SUBS PC, LR and related instructions \(T32\) on page K1-6109](#).

### Accessing Hyp mode from outside Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in [SRS \(T32\) on page K1-6108](#) and [SRS \(A32\) on page K1-6108](#).

## Modifying PSTATE.M when in Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting **PSTATE.IL** to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in [SRS \(T32\) on page K1-6108](#) and [SRS \(A32\) on page K1-6108](#).

## Use of Hyp mode in Secure state

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting **PSTATE.IL** to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in [SRS \(T32\) on page K1-6108](#) and [SRS \(A32\) on page K1-6108](#).

## Execution of Load/Store unprivileged instructions in Hyp mode

If LDRT, LDRSHT, LDRHT, LDRSBT, LDRBT, STRT, STRHT or STRBT are executed in Hyp mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the equivalent, corresponding LDR, LDRSH, LDRH, LDRSB, LDRB, STR, STRH or STRB instruction in Hyp mode.

## Exception return to Hyp mode

Exception returns to Hyp mode when **SCR.NS** == 0 or from a Non-secure PL1 mode invokes the ARMv8 illegal exception return.

## Accessing registers that cannot be accessed using MSR/MRS instructions

The following MSR and MRS instructions can lead to CONSTRAINED UNPREDICTABLE behavior:

```
MSR <Rm>_<mode>, <Rn>
MSR SPSR_<mode>, <Rn>
MSR ELR_hyp, <Rn>
MRS <Rn>, <Rm>_<mode>
MRS <Rn>, SPSR_<mode>
MRS <Rn>, ELR_hyp
```

If these instructions are executed in either Secure or Non-secure User mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the MSR and MRS instructions attempt to access a register that cannot be legally accessed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- For MRS instructions, the destination general-purpose register becomes UNKNOWN.
- For MSR instructions, if the register specified could be accessed from the current mode by other mechanisms, then this register is UNKNOWN. Otherwise the instruction executes as a NOP.

## Memory type handling

If the attributes for a memory location after combining stage 1 and stage 2 of a translation regime is Normal Inner Non-cacheable, Outer Non-cacheable, then the shareability attributes after combining the two stages of translation is Outer Shareable.

## Hyp mode TLB maintenance instructions

If a [TLBIMVAH](#), [TLBIMVALH](#), [TLBIMVAHIS](#), [TLBIMVALHIS](#), [TLBIALLH](#), [TLBIALLHIS](#), [TLBIALLNSNH](#), [TLBIALLNSNHIS](#), [TLBIIPAS2](#), [TLBIIPAS2L](#), [TLBIIPAS2IS](#), or [TLBIIPAS2LIS](#) instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is executed as if it had been executed in Monitor mode.

For more information about these instructions see [The scope of TLB maintenance instructions on page G4-4641](#).

## Hyp mode VA to PA address translation instructions

If an [ATS1HR](#) or [ATS1HW](#) instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is executed as if it had been executed in Monitor mode.

For more information about these instructions see [Address translation instruction naming and operation summary on page G4-4682](#).

## Stage 1 default memory type

If [HCR.DC](#) == 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with:

- [SCTLR.M](#) == 0, regardless of the actual value of [SCTLR.M](#), other than for the value returned by an explicit read of [SCTLR.M](#).
- [HCR.VM](#) == 1, regardless of the actual value of [HCR.VM](#), other than for an explicit read of this bit.

## Trapping of general exceptions to Hyp mode

Attempting to perform an exception return to a Non-secure PL1 mode when [HCR.TGE](#) == 1 invokes an illegal exception return.

Attempting to change from Monitor mode to a Non-secure PL1 mode when [HCR.TGE](#) == 1 by executing a CPS or MSR instruction generates an Illegal Execution state exception, by not changing the mode, and setting [PSTATE.IL](#) to 1.

When EL3 is using AArch32, attempting to change from a Secure PL1 mode to a Non-secure PL1 mode when [HCR.TGE](#) is set, by changing [SCR.NS](#) from 0 to 1, results in no change of [SCR.NS](#).

Because taking an exception into Non-secure PL1 modes leads to a CONSTRAINED UNPREDICTABLE situation, the following additional properties apply when [HCR.TGE](#) == 1:

- All exceptions that would be routed to EL1 are routed to EL2.
- Non-secure [SCTLR.M](#) is treated as being 0, regardless of its actual value, other than for an explicit read of this bit.
- [HCR.FMO](#), [HCR.IMO](#), and [HCR.AMO](#) are treated as being 1, regardless of their actual value, other than for an explicit read of these bits.

- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signalling virtual interrupts are disabled.

### Prevention of rootkits using Hyp mode or Secure state

If an [HVC](#) instruction is executed in Hyp mode when [SCR.HCE](#) == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If an [SMC](#) instruction is executed in a Secure privileged mode when [SCR.SCD](#) == 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

### HVC

For a description of this instruction and the encoding, see [HVC on page F5-3123](#).

For the A1 encoding, if `cond field != 1110`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

### MSR/MRS Banked registers

[Encoding and use of Banked register transfer instructions on page F5-3674](#) identifies cases where attempted execution of an MRS (Banked register) or MSR (Banked register) was UNPREDICTABLE in ARMv7 and becomes CONSTRAINED UNPREDICTABLE in ARMv8. This includes cases where:

- The target register specified by the {R, SYSm} fields of the instruction encoding is not accessible from the PE mode in which the instruction was executed, see [Usage restrictions on the Banked register transfer instructions on page F5-3675](#).
- The instruction was executed specifying unallocated {R, SYSm} field values, see [Encoding the register argument in the Banked register transfer instructions on page F5-3676](#).

If one of these encodings for the MSR/MRS (Banked register) instructions is executed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- An allocated MSR/MRS (Banked register) instruction is executed.

## K1.1.31 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within the AArch32 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
- The encoding causes the field to have no functional effect.

---

**Note**

---

These constraints are identical to those for the equivalent AArch64 definitions, as given in [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-6133.

---

### K1.1.32 CONSTRAINED UNPREDICTABLE behavior in Debug state

[Behavior in Debug state on page H2-5445](#) of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

## K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors

It contains the following sections:

- [Overview of the constraints on AArch64 UNPREDICTABLE behaviors.](#)
- [SBZ or SBO fields in A64 instructions.](#)
- [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6120.](#)
- [CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-6120.](#)
- [Translation table base address alignment on page K1-6121.](#)
- [The Performance Monitors Extension on page K1-6121.](#)
- [Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page K1-6122.](#)
- [Out of range virtual address on page K1-6122.](#)
- [Instruction fetches from Device memory on page K1-6122.](#)
- [Programming the CSSELR\\_EL1.Level for a cache level that is not implemented on page K1-6123.](#)
- [Crossing a page boundary with different memory types or Shareability attributes on page K1-6123.](#)
- [Crossing a peripheral boundary with a Device access on page K1-6123.](#)
- [CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-6124.](#)
- [CONSTRAINED UNPREDICTABLE behavior for A64 instructions on page K1-6124.](#)
- [Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-6133.](#)
- [Reserved values in System and memory-mapped registers and translation table entries on page K1-6133.](#)
- [CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-6133.](#)

### K1.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

#### ————— Note —————

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

### K1.2.2 SBZ or SBO fields in A64 instructions

Some A64 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO, as described in [Fixed values in AArch64 instruction and System register descriptions on page C2-151](#). Except for specific cases identified in [CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-6124](#), if the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

### K1.2.3 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes ARMv8.2-TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

#### ————— Note —————

If the effective control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that effective value must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits in a TLB might generate an exception, reporting the exception using the TLB conflict fault code, see [TLB conflict aborts on page D4-2118](#).

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

### K1.2.4 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

## K1.2.5 Translation table base address alignment

In the translation table base registers `TTBR0_EL1`, `TTBR1_EL1`, `TTBR0_EL2`, `VTTBR_EL2`, and `TTBR0_EL3`, register bits[48:*x*] hold the translation table base address, where *x* depends on the translation table granule size and the size of the addressed translation table, as described in *Memory translation granule size on page D4-2021*. Register bits[(*x*-1):0], **unless redefined for another purpose**, correspond to bits[(*x*-1):0] of the translation table base address and therefore are RES0.

### Note

- When ARMv8.2-LPA is implemented and the 64KB granule size is used, register bits[5:2] are redefined to hold bits[51:48] of the translation table base address.
- When ARMv8.2-TTCNP is implemented register bit[0] is redefined as the CnP bit.

For these registers, if one or more RES0 bits in register bits [(*x*-1):0] does not have a value of 0, this can result in a misaligned translation table base address. In this case, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all the bits had a value of 0:
  - The value read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using those registers might be corrupted in those bits that are nonzero.

For more information, see the appropriate `TTBR.BADDR` field description.

## K1.2.6 The Performance Monitors Extension

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If `PMSELR_EL0.SEL` is not equal to 31, and `PMSELR_EL0.SEL` is greater than or equal to `PMCR_EL0.N`, and the PE is executing in an Exception level in Secure state or in EL2.
- If `PMSELR_EL0.SEL` is not 31, and `PMSELR_EL0.SEL` is greater than or equal to `MDCR_EL2.HPMN`, and the PE is executing in an Exception level in Non-secure state other than in EL2.

In these cases, one of the following behaviors must occur:

- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state are UNDEFINED.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state behave as RAZ/WI.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state execute as NOPs.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state behave as if `PMSELR_EL0.SEL` contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state behave as if `PMSELR_EL0.SEL` is 31.
- In Non-secure state, for an access to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from EL0 are permitted when:
  - EL1 is using AArch32 and the value of `PMUSERENR.EN` is 1.
  - EL1 is using AArch64 and the value of `PMUSERENR_EL0.EN` is 1.

If `PMSELR_EL0.SEL` is equal to 31, then one of the following behaviors must occur:

- Accesses to `PMXVCNTR_EL0` are UNDEFINED.
- Accesses to `PMXVCNTR_EL0` behave as RAZ/WI.
- Accesses to `PMXVCNTR_EL0` execute as NOPs.

- Accesses to `PMXEVCNTR_EL0` behave as if `PMSELR_EL0.SEL` contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.

If `MDCR_EL2.HPMN` is set to 0, or to a value larger than `PMCR_EL0.N`, then the following CONSTRAINED UNPREDICTABLE behavior applies:

- The value returned by a direct read of `MDCR_EL2.HPMN` is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if `MDCR_EL2.HPMN` is set to an UNKNOWN non-zero value less than `PMCR_EL0.N`.
  - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

### K1.2.7 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, `ESR_ELx` is UNKNOWN.

#### ———— Note ————

The value written to `ESR_ELx` must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

### K1.2.8 Out of range virtual address

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and where the computed virtual address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address.

If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the computed address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address and the tags associated with address also become UNKNOWN.

#### ———— Note ————

Because of program counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes both the byte at virtual address `0xFFFF FFFF FFFF FFFF` and the byte at virtual address `0x0000 0000 0000 0000`.

### K1.2.9 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when address translation is enabled.

If a branch causes the program counter to point to an area of memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

### K1.2.10 Programming the CSSELR\_EL1.Level for a cache level that is not implemented

If the CSSELR\_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSELR\_EL1 returns an UNKNOWN value in CSSELR\_EL1.Level.

If the CSSELR\_EL1.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR\_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR\_EL1 read executes as a NOP.
- The CCSIDR\_EL1 read is UNDEFINED.
- The CCSIDR\_EL1 read returns an UNKNOWN value.

### K1.2.11 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an Alignment fault caused by the memory type.

For the Non-secure EL1&0 translation regime:

- If the stage 1 translation generated the mismatch then the resulting exception is taken to EL1.
- If the stage 2 translation generated the mismatch then the resulting exception is taken to EL2.
- If both stages of translation generate the mismatch then the exception can be taken to either EL1 or EL2.

- The instruction executes as a NOP.

### K1.2.12 Crossing a peripheral boundary with a Device access

Performing memory accesses from one load or store instruction to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The instruction generates an alignment fault caused by the memory type.

For the Non-secure EL1&0 translation regime:

- If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to EL1.
- If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to EL2.
- If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either EL1 or EL2.

- The instruction executes as a NOP.

———— **Note** ————

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.

### K1.2.13 CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

*Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-128* defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. In summary, these cases are:

- The target virtual address of a StoreExc1 instruction is different from the virtual address of the preceding LoadExc1 instruction in the same thread of execution.
- The transaction size of a StoreExc1 instruction is different from the transaction size of the preceding LoadExc1 instruction in the same thread of execution.
- The StoreExc1 instruction accesses a different number of registers than the preceding LoadExc1 instruction in the same thread of execution.
- The memory attributes for a StoreExc1 instruction are different from the memory attributes for the preceding LoadExc1 instruction in the same thread of execution, either:
  - Because the translation of the accessed address changes between the LoadExc1 instruction and the StoreExc1 instruction.
  - Because the LoadExc1 instruction and the StoreExc1 instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in *Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-128* for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

### K1.2.14 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in *Chapter C6 A64 Base Instruction Descriptions* and *Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions*.

#### LDAXP

For a description of this instruction and the encoding, see *LDAXP on page C6-641*.

#### CONSTRAINED UNPREDICTABLE behavior

If  $t == t2$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

## LDNP

For a description of this instruction and the encoding, see [LDNP on page C6-662](#).

### CONSTRAINED UNPREDICTABLE behavior

If  $t == t2$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

## LDNP (SIMD&FP)

For a description of this instruction and the encoding, see [LDNP \(SIMD&FP\) on page C7-1353](#).

### CONSTRAINED UNPREDICTABLE behavior

If  $t == t2$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

## LDP

For a description of this instruction and the encoding, see [LDP on page C6-664](#).

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $(t == n \mid t2 == n) \&\& n \neq 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If  $t == t2$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

### ————— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

## LDP (SIMD&FP)

For a description of this instruction and the encoding, see [LDP \(SIMD&FP\) on page C7-1355](#).

### CONSTRAINED UNPREDICTABLE behavior

If  $t == t2$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

## LDPSW

For a description of this instruction and the encoding, see [LDPSW](#) on page C6-667.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $(t == n \mid t2 == n) \&\& n != 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If  $t == t2$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

---

#### Note

Pre-indexed addressing and post-indexed addressing imply writeback.

---

## LDR (immediate)

For a description of this instruction and the encoding, see [LDR \(immediate\)](#) on page C6-670.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \&\& n != 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

---

#### Note

Pre-indexed addressing and post-indexed addressing imply writeback.

---

## LDRB (immediate)

For a description of this instruction and the encoding, see [LDRB \(immediate\)](#) on page C6-677.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

#### ———— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

---

## LDRH (immediate)

For a description of this instruction and the encoding, see [LDRH \(immediate\)](#) on page C6-681.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

#### ———— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

---

## LDRSB (immediate)

For a description of this instruction and the encoding, see [LDRSB \(immediate\)](#) on page C6-685.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t \ \&\& \ n \neq 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

#### ———— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

---

## LDRSH (immediate)

For a description of this instruction and the encoding, see [LDRSH \(immediate\)](#) on page C6-690.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t$  &&  $n != 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

---

#### Note

Pre-indexed addressing and post-indexed addressing imply writeback.

---

## LDRSW (immediate)

For a description of this instruction and the encoding, see [LDRSW \(immediate\)](#) on page C6-695.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t$  &&  $n != 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

---

#### Note

Pre-indexed addressing and post-indexed addressing imply writeback.

---

## LDXP

For a description of this instruction and the encoding, see [LDXP](#) on page C6-748.

### CONSTRAINED UNPREDICTABLE behavior

If  $t == t2$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

## STP

For a description of this instruction and the encoding, see [STP on page C6-867](#).

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $(t == n \mid t2 == n) \&\& n != 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

#### ————— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

## STLXP

For a description of this instruction and the encoding, see [STLXP on page C6-856](#).

### CONSTRAINED UNPREDICTABLE behavior

If  $s == t \mid (s == t2)$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n \&\& n != 31$  then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STLXR

For a description of this instruction and the encoding, see [STLXR on page C6-859](#).

### CONSTRAINED UNPREDICTABLE behavior

If  $s == t$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n \&\& n != 31$  then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STLXRB

For a description of this instruction and the encoding, see [STLXRB](#) on page C6-861.

### CONSTRAINED UNPREDICTABLE behavior

If  $s == t$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n$  &  $n != 31$  then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STLXRH

For a description of this instruction and the encoding, see [STLXRH](#) on page C6-863.

### CONSTRAINED UNPREDICTABLE behavior

If  $s == t$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n$  &  $n != 31$  then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STR (immediate)

For a description of this instruction and the encoding, see [STR \(immediate\)](#) on page C6-870.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t$  &  $n != 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

#### ————— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

## STRB (immediate)

For a description of this instruction and the encoding, see [STRB \(immediate\)](#) on page C6-875.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t$  &&  $n != 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

#### ———— Note ————

Pre-indexed addressing and post-indexed addressing imply writeback.

---

## STRH (immediate)

For a description of this instruction and the encoding, see [STRH \(immediate\)](#) on page C6-879.

### CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and  $n == t$  &&  $n != 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

#### ———— Note ————

Pre-indexed addressing and post-indexed addressing imply writeback.

---

## STXP

For a description of this instruction and the encoding, see [STXP](#) on page C6-920.

### CONSTRAINED UNPREDICTABLE behavior

If  $s == t$  || ( $s == t2$ ), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n$  &&  $n != 31$  then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STXR

For a description of this instruction and the encoding, see [STXR on page C6-922](#).

### CONSTRAINED UNPREDICTABLE behavior

If  $s == t$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n$  &  $n != 31$  then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STXRB

For a description of this instruction and the encoding, see [STXRB on page C6-924](#).

### CONSTRAINED UNPREDICTABLE behavior

If  $s == t$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n$  &  $n != 31$  then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

## STXRH

For a description of this instruction and the encoding, see [STXRH on page C6-926](#).

### CONSTRAINED UNPREDICTABLE behavior

If  $s == t$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If  $s == n$  &  $n != 31$  then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

### K1.2.15 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions [DC C1SW](#), [DC CSW](#), and [DC ISW](#), if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

---

**Note**

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the AArch32 cache maintenance by set/way instructions [DCC1SW](#), [DCCSW](#), and [DC1SW](#).

---

### K1.2.16 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated in this manual, all unallocated or reserved values of fields with allocated values within AArch64 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The unallocated value maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The unallocated value causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value causes the field to have no functional effect.

---

**Note**

These constraints are identical to those for the equivalent AArch32 definitions, as given in [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

---

### K1.2.17 CONSTRAINED UNPREDICTABLE behavior in Debug state

[Behavior in Debug state on page H2-5445](#) of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

## Appendix K2

# Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

- [About the recommended external debug interface on page K2-6136.](#)
- [PMUEVENT bus on page K2-6139.](#)
- [Recommended authentication interface on page K2-6140.](#)
- [Management registers and CoreSight compliance on page K2-6141.](#)

---

### **Note**

This recommended external debug interface specification is not part of the ARM architecture specification. Implementers and users of the ARMv8 architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

- As reference material for users of ARM products that implement this interface.
- As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any ARM products might, or might not, implement this external debug interface. For details of the implemented external debug interface you must always see the appropriate product documentation.

---

## K2.1 About the recommended external debug interface

See the *Note* on the first page of this appendix for information about the architectural status of this recommended debug interface.

This specification provides a recommended external debug interface for ARMv8 to define a standard set of connections for validation environments. In general, the connection between components, such as between the PE and Trace extension, is not described here, although the table does include the signals for the CTI connection.

[Table K2-1](#) shows the signals in the recommended interface.

**Table K2-1 Recommended debug interface signals**

Name	Direction	Description	Notes
<b>DBGEN</b>	In	External debug enable	-
<b>SPIDEN</b>	In	Secure privileged external debug enable	-
		Secure privileged self-hosted debug enable	Only in Secure AArch32 modes when enabled by <a href="#">MDCR_EL3.SPD32</a>
<b>NIDEN</b>	In	External profiling and trace enable	-
<b>SPNIDEN</b>	In	Secure external profiling and trace enable	-
<b>EDBGRQ</b>	In	External halt request	Provided for legacy connections only.
<b>DBGACK</b>	Out	External halt request acknowledge	
<b>COMMIRQ</b>	Out	DCC interrupt	Interface to an interrupt controller. See <a href="#">Interrupt-driven use of the DCC on page H4-5514</a> and the pseudocode for function <a href="#">CheckForDCCInterrupts()</a> .
<b>PMUIRQ</b>	Out	Performance Monitor overflow	Interface to an interrupt controller. See <a href="#">Behavior on overflow on page D5-2142</a> .
<b>COMMRX</b>	Out	DTRRX is full	Provided for legacy connection to an interrupt controller only. See <a href="#">Interrupt-driven use of the DCC on page H4-5514</a> and the pseudocode for function <a href="#">CheckForDCCInterrupts()</a> .
<b>COMMTX</b>	Out	DTRTX is empty	
<b>PMUEVENT[n:0]</b>	Out	Performance Monitors event bus	See <a href="#">PMUEVENT bus on page K2-6139</a> .
<b>DBGNOPWRDWN</b>	Out	Core no powerdown request	Interface to a power controller. See <a href="#">DBGPRCR_EL1.CORENPDRQ</a> .
<b>DBGPWRUPREQ</b>	Out	Core powerup request	Interface to a power controller. See <a href="#">EDPRCR.COREPURQ</a> .
<b>DBGRSTREQ</b>	Out	Warm reset request	Interface to a power controller. See <a href="#">EDPRCR.CWRR</a> .
<b>DBGBUSCANCELREQ</b>	Out	All asynchronous entry to Debug state	Extension to the bus interface. See <a href="#">EDRCR.CBRRQ</a> .
<b>DBGPWRDUP</b>	In	Core powerup status	Interface to a power controller. See <a href="#">EDPRSR.PU</a> .
<b>DBGROMADDR[n:12]</b>	In	<a href="#">MDRAR_EL1.ROMADDR</a>	<i>n</i> depends on the size of the physical address space.

Table K2-1 Recommended debug interface signals (continued)

Name	Direction	Description	Notes
DBGROMADDRV	In	<a href="#">MDRAR_EL1</a> . Valid	-
PRESETDBG	In	External debug reset	-
CPUPORESET	In	Cold reset	-
CORERESET	In	Warm reset	-
PSELDBG	In	Debug APB slave port	For details see <i>AMBA APB3</i> . ARM recommends a single slave port for all integrated debug components. <b>PADDRDBG31</b> distinguishes memory-mapped and DAP accesses: <b>0</b> Memory-mapped access <b>1</b> DAP access
PENABLEDBG	In		
PWRITEDBG	In		
PRDATADBG[31:0]	Out		
PWDATADBG[31:0]	In		
PADDRDBG[n:2] <sup>a</sup>	In		
PREADYDBG	Out		
PSLVERRDBG	Out		
PCLKDBG	In		
PCLKENDBG	In		
CTICHIN	In	CoreSight channel interface	For details, see the <i>ARM® CoreSight™ Architecture Specification</i> . The ACK signals are not required if the channel interface is synchronous.
CTICHOUTACK	In		
CTICHOUT	Out		
CTICHINACK	Out		
CTHRQ	Out	CTI interrupt, see <a href="#">Description and allocation of CTI triggers</a> on page H5-5525	Implements a handshake for an edge-sensitive interrupt.
CTHRQACK	In		
ATDATA[nx8-1:0]	Out	AMBA 4 ATB interface	For details, see the <i>AMBA 4 ATB Protocol Specification, ATBv1.0 and ATBv1.1</i> . Only available if the OPTIONAL Trace extension is implemented.
ATBYTES[n-1:0]	Out		
ATID[6:0]	Out		
ATREADY	In		
ATVALID	Out		
AFREADY	Out		
AFVALID	Out		
SYNCREQ	In		
ATCLK	In		
ATCLKEN	In		
ATRESET	In		

a. The value of *n* depends on the size of the address space occupied by the Debug port.

Figure K2-1 shows the recommended debug interface.

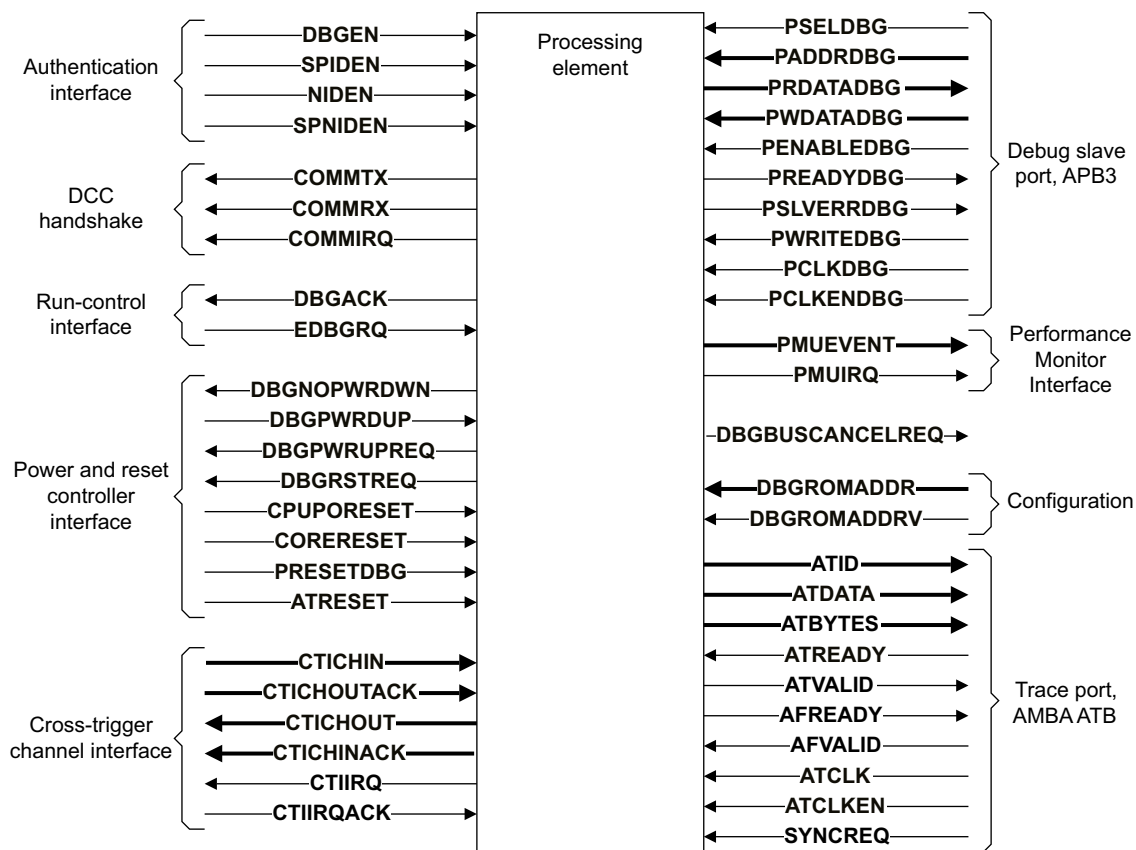

Figure K2-1 Recommended external debug interface, including the APB3 slave port

## K2.2 PMUEVENT bus

The **PMUEVENT** bus exports Performance Monitor events from the PE to an on-chip agent. ARM recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. ARM recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
  - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
  - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
  - Using a single bit encoding to indicate whether the event count is zero or nonzero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If a Trace extension is implemented, the **PMUEVENT** bus is normally connected to the Trace extension using the external inputs. TRCEXTINSEL multiplexes a wide **PMUEVENT** bus to a narrow set of inputs. An external **PMUEVENT** bus might also be provided. For more information, contact ARM.

## K2.3 Recommended authentication interface

An implementation of the ARMv8 architecture must support debug authentication described in [Required debug authentication on page H1-5432](#).

The details of the debug authentication interface are IMPLEMENTATION DEFINED, but ARM recommends the use of the CoreSight interface, which includes the following signals for external debug authentication:

- **DBGEN**.
- **SPIDEN**.
- **NIDEN**.
- **SPNIDEN**.

ARM recommends an interface in which **DBGEN** and **SPIDEN** are also used for self-hosted Secure debug authentication if either:

- EL3 is using AArch32 and **SDCR.SPD** == 0b00.
- Secure EL1 is using AArch32 and **MDCR\_EL3.SPD32** == 0b00.

If EL3 is not implemented and the PE is in Non-secure state, **SPIDEN** and **SPNIDEN** are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, **SPIDEN** is usually connected to **DBGEN** and **SPNIDEN** is connected to **NIDEN**, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. ARM recommends that any Trace extension has the same authentication interface as the PE it is connected to.

[Table K2-2](#) shows the debug authentication pseudocode functions and the recommended implementations.

**Table K2-2 Recommended implementation of debug enable pseudocode functions**

Pseudocode function	Description	Implementation
<a href="#">AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()</a>	Secure invasive self-hosted debug enabled in AArch32 state (legacy)	<b>(DBGEN AND SPIDEN)</b>
<a href="#">ExternalSecureNoninvasiveDebugEnabled()</a>	Secure non-invasive debug enabled	<b>(DBGEN OR NIDEN) AND (SPIDEN OR SPNIDEN)</b>
<a href="#">ExternalSecureInvasiveDebugEnabled()</a>	Secure invasive debug enabled	<b>(DBGEN AND SPIDEN)</b>
<a href="#">ExternalNoninvasiveDebugEnabled()</a>	Non-secure non-invasive debug enabled	<b>(DBGEN OR NIDEN)</b>
<a href="#">ExternalInvasiveDebugEnabled()</a>	Non-secure invasive debug enabled	<b>DBGEN</b>

The [Debug\\_authentication\(\)](#) pseudocode function on [shared/debug on page J1-6006](#) defines the authentication signals **DBGEN**, **SPIDEN**, **NIDEN** and **SPNIDEN**.

## K2.4 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from 0xF00 upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but ARM recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from 0xEFC downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from 0xE80 to 0xEFC for this purpose.

### K2.4.1 Coresight interface register map

Table K2-3 shows the external management register maps for the following registers:

**ED** These are the external debug register.  
**CTI** These are the Cross-trigger interface registers.  
**PMU** These are the Performance Monitors registers.

Table K2-3 Coresight interface register map

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xF00	EDITCTRL	CTIITCTRL	PMITCTRL	Integration Model Control registers
0xF04-0xF9C	-	-	-	Reserved, RES0
0xFA0	DBGCLAIMSET_EL1 <sup>a</sup>	CTICLAIMSET <sup>b</sup>	-	CLAIM Tag Set registers
0xFA4	DBGCLAIMCLR_EL1 <sup>a</sup>	CTICLAIMCLR <sup>b</sup>	-	CLAIM Tag Clear registers
0xFA8	EDDEVAFF0 <sup>a</sup>	CTIDEVAFF0 <sup>c</sup>	PMDEVAFF0	Device Affinity registers
0xFAC	EDDEVAFF1 <sup>a</sup>	CTIDEVAFF1 <sup>c</sup>	PMDEVAFF1	
0xFB0	EDLAR <sup>d</sup>	CTILAR <sup>d</sup>	PMLAR <sup>d</sup>	Lock Access register
0xFB4	EDLSR <sup>d</sup>	CTILSR <sup>d</sup>	PMLSR <sup>d</sup>	Lock Status register
0xFB8	DBGAUTHSTATUS_EL1 <sup>a</sup>	CTIAUTHSTATUS	PMAUTHSTATUS	Authentication Status register
0xFBC	EDDEVARCH	CTIDEVARCH	PMDEVARCH	Device Architecture register
0xFC0	EDDEVID2 <sup>a</sup>	CTIDEVID2 <sup>a</sup>	-	Device ID register
0xFC4	EDDEVID1 <sup>a</sup>	CTIDEVID1 <sup>a</sup>	-	
0xFC8	EDDEVID <sup>a</sup>	CTIDEVID <sup>a</sup>	PMDEVID <sup>a</sup>	
0xFCC	EDDEVTYPE	CTIDEVTYPE	PMDEVTYPE	Device Type register
0xFD0	EDPIDR4	CTIPIDR4	PMPIDR4	Peripheral ID registers
0xFD4-0xFDC	-	-	-	Reserved, RES0
0xFE0	EDPIDR0	CTIPIDR0	PMPIDR0	Peripheral ID registers
0xFE4	EDPIDR1	CTIPIDR1	PMPIDR1	
0xFE8	EDPIDR2	CTIPIDR2	PMPIDR2	
0xFEC	EDPIDR3	CTIPIDR3	PMPIDR3	

Table K2-3 Coresight interface register map (continued)

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xFF0	EDCIDR0	CTICIDR0	PMCIDR0	Component ID registers
0xFF4	EDCIDR1	CTICIDR1	PMCIDR1	
0xFF8	EDCIDR2	CTICIDR2	PMCIDR2	
0xFFC	EDCIDR3	CTICIDR3	PMCIDR3	

- This register must always be implemented, regardless of whether the component is CoreSight compliant.
- If implemented, the number of CLAIM bits is IMPLEMENTATION DEFINED and can be discovered by reading CLAIMSET.
- If the CTI implements CTIv1, this register is not implemented. See the register description for details.
- The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

## K2.4.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

If the Debug power domain is off, all register accesses return an error.

Otherwise, [Table K2-4 on page K2-6143](#), [Table K2-5 on page K2-6144](#), and [Table K2-6 on page K2-6145](#) show the response to accesses by the external debug interface to the CoreSight management registers. For definitions of the terms used in the tables, see [External debug interface register access permissions summary on page H8-5563](#).

### Note

Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

[Table K2-4 on page K2-6143](#), [Table K2-5 on page K2-6144](#), and [Table K2-6 on page K2-6145](#) include reserved management registers, because the CoreSight architecture requires that these registers are always RES0. The descriptions in [Reserved and unallocated registers on page H8-5563](#) does not apply to reserved management registers if the implementation is CoreSight compliant.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See [Register access permissions for memory-mapped accesses on page H8-5558](#).

The terms in [Table K2-4 on page K2-6143](#), [Table K2-5 on page K2-6144](#), and [Table K2-6 on page K2-6145](#) are defined as follows:

**Domain** This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

**Conditions** This lists the conditions under which the access is attempted.  
To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

**Off** [EDPRSR.PU](#) == 0. The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

### Note

If debug power is off, then all external debug interface accesses return an error.

**DLK** [DoubleLockStatus\(\)](#) == TRUE. The OS Double Lock is locked.

**OSLK** [OSLSR.OSLK](#) == 1. The OS Lock is locked.

- Default** This provides the default access permissions, if there are no conditions that prevent access to the register.
- SLK** This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See [Register access permissions for memory-mapped accesses on page H8-5558](#). For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.
- RO** This means that the register or field is read-only.
- RW** This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.
- RC** This means that the bit clears to 0 after a read.
- (SE)** This means that accesses to this register have indirect write side effects. A side effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.
- WO** This means that the register or field is write-only.
- WI** This means that the register or field ignores writes.
- IMP DEF** This means that the access permissions are IMPLEMENTATION DEFINED.

**Table K2-4 External debug interface access permissions, CoreSight registers (debug)**

Offset	Register	Domain	Conditions (priority left to right)			Default	SLK
			Off	DLK	OSLK

### K2.4.3 Management register resets

Table K2-7 shows the management register resets. This table does not include:

- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID{n}, DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

Table K2-7 shows a summary of the management register resets.

**Table K2-7 Management register resets**

Register	Reset domain	Field	Value	Description
CTIITCTRL EDITCTRL PMITCTRL	IMPLEMENTATION DEFINED	IME	0	Integration mode enable
DBGCLAIMCLR_EL1	Cold reset	CLAIM	0x00	CLAIM tags
CTICLAIMCLR	External debug	CLAIM	0x00000000	
CTILSR <sup>a</sup> EDLSR <sup>a</sup> PMLSR <sup>a</sup>	External debug	SLK	1	Software Lock

a. Only if the OPTIONAL Software Lock is implemented

### K2.4.4 About the Peripheral identification scheme

The Peripheral Identification scheme provides the standard information required by all components that conform to the *ARM® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2*, that implements the CoreSight identification scheme. They identify a peripheral in a particular namespace. For more information, see the *ARM® CoreSight™ Architecture Specification*.

Table K2-8 on page K2-6147 lists the Peripheral ID Registers that make up the Peripheral Identification scheme for each component.

**Table K2-8 Peripheral Identification Registers**

Register offset	Description	Reference		
		External Debug	CTI	Performance Monitors
0xFD0	Peripheral ID4	EDPIDR4	CTIPIDR4	PMPIDR4
0xFD4	Reserved for Peripheral ID5	-	-	-
0xFD8	Reserved for Peripheral ID6	-	-	-
0xFDC	Reserved for Peripheral ID7	-	-	-
0xFE0	Peripheral ID0	EDPIDR0	CTIPIDR0	PMPIDR0
0xFE4	Peripheral ID1	EDPIDR1	CTIPIDR1	PMPIDR1
0xFE8	Peripheral ID2	EDPIDR2	CTIPIDR2	PMPIDR2
0xFEC	Peripheral ID3	EDPIDR3	CTIPIDR3	PMPIDR3

Figure K2-2 shows the register field allocation scheme for the Peripheral ID Registers.

**Figure K2-2 Peripheral ID register format**

Software can consider the eight Peripheral ID Registers as defining a single 64-bit Peripheral ID, as shown in Figure K2-3.

**Figure K2-3 Mapping between Peripheral ID Registers and a 64-bit Peripheral ID Value**

Figure K2-3 shows the fields in the 64-bit Peripheral ID value, and includes the field values for fields that:

- Have fixed values, including the bits that are reserved.
- Have fixed values in an implementation that is designed by ARM.

For more information about the fields and their values see Table K2-9 on page K2-6148.

**Figure K2-4 Peripheral ID fields, with values for a implementation designed by ARM**

Table K2-9 shows the fields in the Peripheral ID.

**Table K2-9 Fields in the Peripheral Identification Registers**

Name	Size	Description	Registers
4KB count	4 bits	Log2 of the number of 4KB blocks occupied by the implementation.	EDPIDR4 CTIPIDR4 PMPIDR4
JEP106 code	4+7 bits	Identifies the designer of the implementation. This value consists of: <ul style="list-style-type: none"> <li>A 4-bit continuation code, also described as the bank number.</li> <li>A 7-bit identification code.</li> </ul> For implementations designed by ARM, the continuation code is 0x4, indicating bank 5, and the identity code is 0x3B.	EDPIDR1, EDPIDR2, EDPIDR4 CTIPIDR1, CTIPIDR2, CTIPIDR4 PMPIDR1, PMPIDR2, PMPIDR4
RevAnd	4 bits	Manufacturing revision number. Indicates a late modification to the implementation, usually as a result of an <i>Engineering Change Order</i> (ECO). This field starts at 0x0 and is incremented by the integrated circuit manufacturer on metal fixes.	EDPIDR3 CTIPIDR3 PMPIDR3
Customer modified	4 bits	Indicates an endorsed modification to the implementation. If the system designer cannot modify the implementation supplied by the implementation designer then this field is RES0.	EDPIDR3 CTIPIDR3 PMPIDR3
Revision	4 bits	Revision number for the implementation. Starts at 0x0 and increments by 1 at both major and minor revisions.	EDPIDR2 CTIPIDR2 PMPIDR2
Uses JEP106 ID code	1 bit	This bit is set to 1 when a JEP106 identification code is used. This bit must be 1 on all ARMv8 implementations.	EDPIDR2 CTIPIDR2 PMPIDR2
Part number	12 bits	Part number for the implementation. Each organization designing to the ARM Debug architecture specification keeps its own part number list.	EDPIDR0, EDPIDR1 CTIPIDR0, CTIPIDR1 PMPIDR0, PMPIDR1

A component is identified uniquely by the combination of the following fields:

- JEP106 continuation code.
- JEP106 identity code.
- Part number.
- Revision.
- Customer Modified.
- RevAnd.

For components with a *Component class* of 0x9, Debug component, indicated by the Component Identification Registers, multiple components can have the same Part number, provided each component has a different CoreSight *Device type*. However, ARM strongly recommends that each device has a unique Part number. For more information:

- About the Component Identification Registers, see [About the Component Identification scheme on page K2-6149](#).
- About the CoreSight Device type, see [EDDEVTYPE](#), [CTIDEVTYPE](#), or [PMDEVTYPE](#).
- About CoreSight components and their identification, see the *ARM® Debug Interface Architecture Specification*.

## Allocating revisions and part numbers

Within the Peripheral Identification registers, the allocation of major and minor revisions, part numbers, and customer-modified fields is IMPLEMENTATION DEFINED, with the following set of restrictions so that:

- The REVISION field must increase monotonically with revisions.

### ————— **Note** —————

ARM recommends that the REVISION field is updated for each update to the RTL, regardless of whether this is a major or minor update.

- The REVAND field should increase monotonically with revisions.

### ————— **Note** —————

ARM recommends that the REVAND field is used only for post-release changes. For example, those due to engineering change order (ECO) fixes related to the debug component of the processor.

- The PART field must have a degree of uniqueness:

- Two component designs can have the same part number so long as they are sub-components of the same part and the programmers' model for the part has the means to disambiguate sub-components.
- Otherwise, two component designs must have unique part numbers.

The DEVARCH (if implemented) or DEVTYPE (otherwise) register provides the means to disambiguate sub-components of the Debug Architecture.

A ROM table has no DEVTYPE or DEVARCH register. However, if it is the only CLASS 0x1 component in a processor cluster, it can still be disambiguated.

Multiple instances of the same component design have the same part number.

## K2.4.5 About the Component Identification scheme

The Component Identification Registers identify the processor as an ARM Debug Interface v5 component. For more information, see the *ARM® Debug Interface Architecture Specification* and the *ARM® CoreSight™ Architecture Specification*.

The Component Identification Registers occupy the last four words of the 4KB block of debug registers.

**Table K2-10 Component Identification Registers**

Register offset	Description	External debug	CTI	Performance Monitors
0xFF0	Component ID0	EDCIDR0	CTICIDR0	PMCIDR0
0xFF0	Component ID1	EDCIDR1	CTICIDR1	PMCIDR1
0xFF0	Component ID2	EDCIDR2	CTICIDR2	PMCIDR2
0xFF0	Component ID3	EDCIDR3	CTICIDR3	PMCIDR3

Figure K2-5 shows the register field allocation scheme for the Component ID Registers.

**Figure K2-5 Component ID Register format**

Software can consider the eight Component ID Registers as defining a single 32-bit Component ID, as shown in Figure K2-6 on page K2-6150.

**Figure K2-6 Mapping between Component ID Registers and a 32-bit Component ID Value**

## Appendix K3

# Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

This appendix describes the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. It contains the following sections:

- *ARM recommendations for IMPLEMENTATION DEFINED event numbers on page K3-6152.*
- *Summary of events for exceptions taken to an Exception level using AArch64 on page K3-6166.*

## K3.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers

These are the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. ARM does not define these events as rigorously as those in the architectural and microarchitectural event lists, and an implementation might:

- Modify the definition of an event to better correspond to the implementation.
- Not use some, or many, of these event numbers.

Table K3-1 lists the PMU IMPLEMENTATION DEFINED event numbers in event number order.

**Table K3-1 PMU IMPLEMENTATION DEFINED event numbers**

Event number	Event mnemonic	Description
0x0040	L1D_CACHE_RD	Attributable Level 1 data cache access, read
0x0041	L1D_CACHE_WR	Attributable Level 1 data cache access, write
0x0042	L1D_CACHE_REFILL_RD <sup>a</sup>	Attributable Level 1 data cache refill, read
0x0043	L1D_CACHE_REFILL_WR <sup>a</sup>	Attributable Level 1 data cache refill, write
0x0044	L1D_CACHE_REFILL_INNER	Attributable Level 1 data cache refill, inner
0x0045	L1D_CACHE_REFILL_OUTER	Attributable Level 1 data cache refill, outer
0x0046	L1D_CACHE_WB_VICTIM	Attributable Level 1 data cache Write-Back, victim
0x0047	L1D_CACHE_WB_CLEAN	Level 1 data cache Write-Back, cleaning and coherency
0x0048	L1D_CACHE_INVALID	Attributable Level 1 data cache invalidate
0x0049-0x004B	-	Reserved
0x004C	L1D_TLB_REFILL_RD <sup>a</sup>	Attributable Level 1 data TLB refill, read
0x004D	L1D_TLB_REFILL_WR <sup>a</sup>	Attributable Level 1 data TLB refill, write
0x004E	L1D_TLB_RD	Attributable Level 1 data or unified TLB access, read
0x004F	L1D_TLB_WR	Attributable Level 1 data or unified TLB access, write
0x0050	L2D_CACHE_RD	Attributable Level 2 data cache access, read
0x0051	L2D_CACHE_WR	Attributable Level 2 data cache access, write
0x0052	L2D_CACHE_REFILL_RD <sup>a</sup>	Attributable Level 2 data cache refill, read
0x0053	L2D_CACHE_REFILL_WR <sup>a</sup>	Attributable Level 2 data cache refill, write
0x0054-0x0055	-	Reserved
0x0056	L2D_CACHE_WB_VICTIM	Attributable Level 2 data cache Write-Back, victim
0x0057	L2D_CACHE_WB_CLEAN	Level 2 data cache Write-Back, cleaning and coherency
0x0058	L2D_CACHE_INVALID	Attributable Level 2 data cache invalidate
0x0059-0x005B	-	Reserved
0x005C	L2D_TLB_REFILL_RD <sup>a</sup>	Attributable Level 2 data or unified TLB refill, read
0x005D	L2D_TLB_REFILL_WR <sup>a</sup>	Attributable Level 2 data or unified TLB refill, write

**Table K3-1 PMU IMPLEMENTATION DEFINED event numbers (continued)**

Event number	Event mnemonic	Description
0x005E	L2D_TLB_RD	Attributable Level 2 data or unified TLB access, read
0x005F	L2D_TLB_WR	Attributable Level 2 data or unified TLB access, write
0x0060	BUS_ACCESS_RD	Bus access, read
0x0061	BUS_ACCESS_WR	Bus access, write
0x0062	BUS_ACCESS_SHARED	Bus access, Normal, Cacheable, Shareable
0x0063	BUS_ACCESS_NOT_SHARED	Bus access, not Normal, Cacheable, Shareable
0x0064	BUS_ACCESS_NORMAL	Bus access, normal
0x0065	BUS_ACCESS_PERIPH	Bus access, peripheral
0x0066	MEM_ACCESS_RD	Data memory access, read
0x0067	MEM_ACCESS_WR	Data memory access, write
0x0068	UNALIGNED_LD_SPEC	Unaligned access, read
0x0069	UNALIGNED_ST_SPEC	Unaligned access, write
0x006A	UNALIGNED_LDST_SPEC	Unaligned access
0x006B	-	Reserved
0x006C	LDREX_SPEC	Exclusive operation speculatively executed, LDREX or LDX
0x006D	STREX_PASS_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x006E	STREX_FAIL_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x006F	STREX_SPEC	Exclusive operation speculatively executed, STREX or STX
0x0070	LD_SPEC	Operation speculatively executed, load
0x0071	ST_SPEC	Operation speculatively executed, store
0x0072	LDST_SPEC	Operation speculatively executed, load or store
0x0073	DP_SPEC	Operation speculatively executed, integer data processing
0x0074	ASE_SPEC	Operation speculatively executed, Advanced SIMD instruction
0x0075	VFP_SPEC	Operation speculatively executed, floating-point instruction
0x0076	PC_WRITE_SPEC	Operation speculatively executed, software change of the PC
0x0077	CRYPTO_SPEC	Operation speculatively executed, Cryptographic instruction
0x0078	BR_IMMED_SPEC	Branch speculatively executed, immediate branch
0x0079	BR_RETURN_SPEC	Branch speculatively executed, procedure return
0x007A	BR_INDIRECT_SPEC	Branch speculatively executed, indirect branch
0x007B	-	Reserved
0x007C	ISB_SPEC	Barrier speculatively executed, ISB
0x007D	DSB_SPEC	Barrier speculatively executed, DSB

**Table K3-1 PMU IMPLEMENTATION DEFINED event numbers (continued)**

Event number	Event mnemonic	Description
0x007E	DMB_SPEC	Barrier speculatively executed, DMB
0x007F-0x0080	-	Reserved
0x0081	EXC_UNDEF	Exception taken, Other synchronous
0x0082	EXC_SVC	Exception taken, Supervisor Call
0x0083	EXC_PABORT	Exception taken, Instruction Abort
0x0084	EXC_DABORT	Exception taken, Data Abort and SError
0x0085	-	Reserved
0x0086	EXC_IRQ	Exception taken, IRQ
0x0087	EXC_FIQ	Exception taken, FIQ
0x0088	EXC_SMC	Exception taken, Secure Monitor Call
0x0089	-	Reserved
0x008A	EXC_HVC	Exception taken, Hypervisor Call
0x008B	EXC_TRAP_PABORT	Exception taken, Instruction Abort not taken locally <sup>b</sup>
0x008C	EXC_TRAP_DABORT	Exception taken, Data Abort or SError not taken locally <sup>b</sup>
0x008D	EXC_TRAP_OTHER	Exception taken, Other traps not taken locally <sup>b</sup>
0x008E	EXC_TRAP_IRQ	Exception taken, IRQ not taken locally <sup>b</sup>
0x008F	EXC_TRAP_FIQ	Exception taken, FIQ not taken locally <sup>b</sup>
0x0090	RC_LD_SPEC	Release consistency operation speculatively executed, Load-Acquire
0x0091	RC_ST_SPEC	Release consistency operation speculatively executed, Store-Release
0x0092-0x009F	-	Reserved
0x00A0	L3D_CACHE_RD	Attributable Level 3 data or unified cache access, read
0x00A1	L3D_CACHE_WR	Attributable Level 3 data or unified cache access, write
0x00A2	L3D_CACHE_REFILL_RD <sup>a</sup>	Attributable Level 3 data or unified cache refill, read
0x00A3	L3D_CACHE_REFILL_WR <sup>a</sup>	Attributable Level 3 data or unified cache refill, write
0x00A4-0x00A5	-	Reserved
0x00A6	L3D_CACHE_WB_VICTIM	Attributable Level 3 data or unified cache Write-Back, victim
0x00A7	L3D_CACHE_WB_CLEAN	Attributable Level 3 data or unified cache Write-Back, cache clean
0x00A8	L3D_CACHE_INVALID	Attributable Level 3 data or unified cache access, invalidate

a. For more information, see *Relationship between REFILL events and associated access events* on page K3-6165.

b. In these definitions, an exception that is *taken locally* means an exception that is taken to the default Exception level, and is not routed to another Exception level. See *Exception levels* on page D1-1776 for more information.

**0x0040, L1D\_CACHE\_RD, Attributable Level 1 data cache access, read**

This event is similar to Level 1 data cache access, [L1D\\_CACHE](#), but the counter counts only memory-read operations that access at least the Level 1 data or unified cache.

**0x0041, L1D\_CACHE\_WR, Attributable Level 1 data cache access, write**

This event is similar to Level 1 data cache access, [L1D\\_CACHE](#), but the counter counts only memory-write operations that access at least the Level 1 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

**0x0042, L1D\_CACHE\_REFILL\_RD, Attributable Level 1 data cache refill, read**

This event is similar to Level 1 data cache refill, [L1D\\_CACHE\\_REFILL](#), but the counter counts only memory-read operations that cause a refill of at least the Level 1 data or unified cache.

See also [Relationship between REFILL events and associated access events](#), on page K3-6165.

**0x0043, L1D\_CACHE\_REFILL\_WR, Attributable Level 1 data cache refill, write**

This event is similar to Level 1 data cache refill, [L1D\\_CACHE\\_REFILL](#), but the counter counts only memory-write operations that cause a refill of at least the Level 1 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

See also [Relationship between REFILL events and associated access events](#), on page K3-6165.

**0x0044, L1D\_CACHE\_REFILL\_INNER, Attributable Level 1 data cache refill, inner**

This event is similar to Level 1 data cache refill, [L1D\\_CACHE\\_REFILL](#), but the counter counts only memory-read and memory-write operations that generate refills satisfied by transfer from another cache inside of the immediate cluster.

**———— Note ————**

The boundary between *inner* and *outer* is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

**0x0045, L1D\_CACHE\_REFILL\_OUTER, Attributable Level 1 data cache refill, outer**

This event is similar to Level 1 data cache refill, [L1D\\_CACHE\\_REFILL](#), but the counter counts only memory-read and memory-write operations that generate refills satisfied from outside of the immediate cluster.

**0x0046, L1D\_CACHE\_WB\_VICTIM, Attributable Level 1 data cache Write-Back, victim**

This event is similar to Level 1 data cache Write-Back, [L1D\\_CACHE\\_WB](#), but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

Write-Backs caused by the execution of a cache maintenance instruction are not counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

**0x0047, L1D\_CACHE\_WB\_CLEAN, Level 1 data cache Write-Back, cleaning and coherency**

This event is similar to Attributable Level 1 data cache Write-Back, [L1D\\_CACHE\\_WB](#), but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

**———— Note ————**

The transfer of a dirty cache line from the Level 1 data cache of this PE to the Level 1 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

**0x0048, L1D\_CACHE\_INVALID, Attributable Level 1 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 1 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally-executed cache maintenance instructions that operate by set/way.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

**0x004C, L1D\_TLB\_REFILL\_RD, Attributable Level 1 data TLB refill, read**

This event is similar to Level 1 data TLB refill, [L1D\\_TLB\\_REFILL](#), but the counter counts only memory-read operations that cause a data TLB refill of at least the Level 1 data or unified TLB.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

**0x004D, L1D\_TLB\_REFILL\_WR, Attributable Level 1 data TLB refill, write**

This event is similar to Level 1 data TLB refill, [L1D\\_TLB\\_REFILL](#), but the counter counts only memory-write operations that cause a data TLB refill of at least the Level 1 data or unified TLB.

The counter counts [DC ZVA](#) as a store instruction.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

**0x004E, L1D\_TLB\_RD, Attributable Level 1 data or unified TLB access, read**

This event is similar to Level 1 data or unified TLB access, [L1D\\_TLB](#), but the counter counts only memory-read operations that cause a TLB access to at least the Level 1 data or unified TLB.

**0x004F, L1D\_TLB\_WR, Attributable Level 1 data or unified TLB access, write**

This event is similar to Level 1 data or unified TLB access, [L1D\\_TLB](#), but the counter counts only memory-write operations that cause a TLB access to at least the Level 1 data or unified TLB.

**0x0050, L2D\_CACHE\_RD, Attributable Level 2 data cache access, read**

This event is similar to Attributable Level 2 data cache access, [L2D\\_CACHE](#), but the counter counts only memory-read operations that access at least the Level 2 data or unified cache.

**0x0051, L2D\_CACHE\_WR, Attributable Level 2 data cache access, write**

This event is similar to Attributable Level 2 data cache access, [L2D\\_CACHE](#), but the counter counts only memory-write operations that access at least the Level 2 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

**0x0052, L2D\_CACHE\_REFILL\_RD, Attributable Level 2 data cache refill, read**

This event is similar to Attributable Level 2 data cache refill, [L2D\\_CACHE\\_REFILL](#), but the counter counts only memory-read operations that cause a refill of at least the Level 2 data or unified cache.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

**0x0053, L2D\_CACHE\_REFILL\_WR, Attributable Level 2 data cache refill, write**

This event is similar to Attributable Level 2 data cache refill, [L2D\\_CACHE\\_REFILL](#), but the counter counts only memory-write operations that cause a refill of at least the Level 2 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

**0x0056, L2D\_CACHE\_WB\_VICTIM, Attributable Level 2 data cache Write-Back, victim**

This event is similar to Attributable Level 2 data cache Write-Back, [L2D\\_CACHE\\_WB](#), but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

Write-Backs caused by the execution of a cache maintenance instruction are not counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

**0x0057, L2D\_CACHE\_WB\_CLEAN, Level 2 data cache Write-Back, cleaning and coherency**

This event is similar to Attributable Level 2 data cache Write-Back, [L2D\\_CACHE\\_WB](#), but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted as IMPLEMENTATION DEFINED.

**Note**

The transfer of a dirty cache line from the Level 2 data cache of this PE to the Level 2 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

**0x0058, L2D\_CACHE\_INVALID, Attributable Level 2 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 2 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally executed cache maintenance instructions that operate by set/way.

**Note**

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting events that directly affect this PE.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

**0x005C, L2D\_TLB\_REFILL\_RD, Attributable Level 2 data or unified TLB refill, read**

This event is similar to Attributable Level 2 data or unified TLB refill, [L2D\\_TLB\\_REFILL](#), but the counter counts only Attributable memory read operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also [Relationship between REFILL events and associated access events](#) on page K3-6165.

**0x005D, L2D\_TLB\_REFILL\_WR, Attributable Level 2 data or unified TLB refill, write**

This event is similar to Attributable Level 2 data or unified TLB refill, [L2D\\_TLB\\_REFILL](#), but the counter counts only Attributable memory write operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also [Relationship between REFILL events and associated access events](#) on page K3-6165.

**0x005E, L2D\_TLB\_RD, Attributable Level 2 data or unified TLB access, read**

This event is similar to Attributable Level 2 data or unified TLB access, [L2D\\_TLB](#), but the counter counts only Attributable memory read operations that cause a TLB access to at least the Level 2 data or unified TLB.

**0x005F, L2D\_TLB\_WR, Attributable Level 2 data or unified TLB access, write**

This event is similar to Attributable Level 2 data or unified TLB access, [L2D\\_TLB](#), but the counter counts only Attributable memory write operations that cause a TLB access to at least the Level 2 data or unified TLB.

**0x0060, BUS\_ACCESS\_RD, Bus access, read**

This event is similar to Bus access, [BUS\\_ACCESS](#), but the counter counts only memory-read operations that access outside the boundary of the PE and its closely-coupled caches.

**0x0061, BUS\_ACCESS\_WR, Bus access, write**

This event is similar to Bus access, [BUS\\_ACCESS](#), but the counter counts only memory-write operations that access outside the boundary of the PE and its closely-coupled caches.

**0x0062, BUS\_ACCESS\_SHARED, Bus access, Normal, Cacheable, Shareable**

This event is similar to Bus access, [BUS\\_ACCESS](#), but the counter counts only memory-read and memory-write operations that make Normal, Cacheable, Shareable accesses outside the boundary of the PE and its closely-coupled caches.

———— **Note** ————

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

**0x0063, BUS\_ACCESS\_NOT\_SHARED, Bus access, not Normal, Cacheable, Shareable**

This event is similar to Bus access, [BUS\\_ACCESS](#), but the counter counts only memory-read and memory-write operations that make accesses outside the boundary of the PE and its closely-coupled caches that are not Normal, Cacheable, Shareable. For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.

———— **Note** ————

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

**0x0064, BUS\_ACCESS\_NORMAL, Bus access, normal**

This event is similar to Bus access, [BUS\\_ACCESS](#), but the counter counts only memory-read and memory-write operations that make Normal accesses outside the boundary of the PE and its closely-coupled caches. For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

**0x0065, BUS\_ACCESS\_PERIPH, Bus access, peripheral**

This event is similar to Bus access, [BUS\\_ACCESS](#), but the counter counts only memory-read and memory-write operations that make Device accesses outside the boundary of the PE and its closely-coupled caches.

**0x0066, MEM\_ACCESS\_RD, Data memory access, read**

This event is similar to Data memory access, [MEM\\_ACCESS](#), but the counter counts only memory-read operations that the PE made.

**0x0067, MEM\_ACCESS\_WR, Data memory access, write**

This event is similar to Data memory access, [MEM\\_ACCESS](#), but the counter counts only memory-write operations made by the PE.

**0x0068, UNALIGNED\_LD\_SPEC, Unaligned access, read**

This event is similar to Data memory access, [MEM\\_ACCESS](#), but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

**0x0069, UNALIGNED\_ST\_SPEC, Unaligned access, write**

This event is similar to Data memory access, [MEM\\_ACCESS](#), but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

**0x006A, UNALIGNED\_LDST\_SPEC, Unaligned access**

This event is similar to Data memory access, [MEM\\_ACCESS](#), but the counter counts only unaligned memory-read operations and unaligned memory-write operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

**0x006C, LDREX\_SPEC, Exclusive operation speculatively executed, Load-Exclusive**

The counter counts Load-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x006D, STREX\_PASS\_SPEC, Exclusive operation speculatively executed, Store-Exclusive pass**

The counter counts Store-Exclusive instructions speculatively executed that completed a write.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [LDREX\\_SPEC](#) event.

**0x006E, STREX\_FAIL\_SPEC, Exclusive operation speculatively executed, Store-Exclusive fail**

The counter counts Store-Exclusive instructions speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [LDREX\\_SPEC](#) event.

**0x006F, STREX\_SPEC, Exclusive operation speculatively executed, Store-Exclusive**

The counter counts Store-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the [LDREX\\_SPEC](#) event.

ARM recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the [LDREX\\_SPEC](#) event.

**0x0070, LD\_SPEC, Operation speculatively executed, load**

This event is similar to Operation speculatively executed, [INST\\_SPEC](#), but the counter counts only memory-reading instructions, as defined by the [LD\\_RETIRED](#) event.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST\\_SPEC](#) event.

**0x0071, ST\_SPEC, Operation speculatively executed, store**

This event is similar to Operation speculatively executed, [INST\\_SPEC](#), but the counter counts only memory-writing instructions, as defined by the [ST\\_RETIRED](#) event.

The counter counts [DC ZVA](#) as a store operation.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST\\_SPEC](#) event.

**0x0072, LDST\_SPEC, Operation speculatively executed, load or store**

This event is similar to Operation speculatively executed, [INST\\_SPEC](#), but the counter counts only memory-reading instructions and memory-writing instructions, as defined by the [LD\\_RETIRED](#) and [ST\\_RETIRED](#) events.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST\\_SPEC](#) event.

**0x0073, DP\_SPEC, Operation speculatively executed, integer data processing**

This event is similar to Operation speculatively executed, [INST\\_SPEC](#), but counts only integer data-processing instructions. It counts the following operations that operate on the general-purpose registers:

- In AArch64 state, [Data processing - immediate on page C3-176](#) and [Data processing - register on page C3-181](#).
- In AArch32 state, [Data-processing instructions on page F1-2812](#).

This includes MOV and MVN operations.

This event also counts the following miscellaneous instructions:

- In AArch64 state, [System register instructions on page C3-158](#), [System instructions on page C3-158](#), and [Hint instructions on page C3-159](#).
- In AArch32 state, [PSTATE and banked register access instructions on page F1-2820](#), [Banked register access instructions on page F1-2820](#), [Miscellaneous instructions on page F1-2825](#), other than ISB and preloads, and [System register access instructions on page F1-2828](#), other than LDC and STC instructions.

If the preload instructions PRFM, PLD, PLDW, and PLI, do not count as memory-reading instructions then they must count as integer data-processing instructions.

If ISBs do not count as software change of the PC then they must count as integer data-processing instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the [INST\\_SPEC](#) event.

It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but ARM recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
  - FMOV (general).
- For AArch64 state, from the SIMD Move group, operations that move a values between a general-purpose register and an element or elements in a SIMD and floating-point register:
  - DUP (general).
  - SMOV.
  - UMOV.
  - INS (general).

- For AArch32 state:
  - VDUP (general-purpose register) and all VMOV instructions that transfer data between a general-purpose register and a SIMD and floating-point register.
  - VMRS.
  - VMSR.

#### 0x0074, ASE\_SPEC, Operation speculatively executed, Advanced SIMD

This event is similar to Operation speculatively executed, [INST\\_SPEC](#), but the counter counts only Advanced SIMD data-processing instructions, see:

- For AArch64 state, the SIMD operations listed in [Data processing - SIMD and floating-point on page C3-189](#).
- For AArch32 state, [Advanced SIMD data-processing instructions on page F1-2832](#).

This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:

- Integer data-processing operations.
- Floating-point data-processing operations.
- Memory-reading operations.
- Memory-writing operations.
- Cryptographic operations other than PMULL, in AArch64 state.
- VMULL, in AArch32 state.

Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, PMULL, and in AArch32 state, VMULL are counted as Advanced SIMD operations.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the [INST\\_SPEC](#) event.

#### 0x0075, VFP\_SPEC, Operation speculatively executed, floating-point

This event is similar to Operation speculatively executed, [INST\\_SPEC](#), but the counter counts only floating-point data-processing instructions, see:

- In AArch64 state, only the scalar floating-point operations listed in [Data processing - SIMD and floating-point on page C3-189](#).

##### **Note**

This event does not count the SIMD floating-point operations listed in [Data processing - SIMD and floating-point on page C3-189](#).

- In AArch32 state, [Floating-point data-processing instructions on page F1-2840](#).

This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:

- Integer data processing.
- Memory-reading operations.
- Memory-writing operations.

The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:

- In AArch64 state, FCVT{<mode>}, UCVTF, and SCVTF.
- In AArch32 state, VCVT<mode>(floating-point), VCVT, VCVTT, and VCVTB.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the [INST\\_SPEC](#) event.

**0x0076, PC\_WRITE\_SPEC, Operation speculatively executed, software change of the PC**

This event is similar to Operation speculatively executed, [INST\\_SPEC](#), but the counter counts only software changes of the PC. Defined by the instruction architecturally executed, condition code check pass, software change of the PC event, see [Common event numbers on page D5-2156](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST\\_SPEC](#) event.

See also [PC\\_WRITE\\_RETIRED](#).

**0x0077, CRYPTO\_SPEC, Operation speculatively executed, Cryptographic instruction**

This event is similar to Operation speculatively executed, [INST\\_SPEC](#), but the counter counts only Cryptographic instructions, except PMULL and VMULL, see [The Cryptographic Extension on page C3-207](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST\\_SPEC](#) event.

**0x0078, BR\_IMMED\_SPEC, Branch speculatively executed, immediate branch**

The counter counts immediate branch instructions speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see [Common event numbers on page D5-2156](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also [BR\\_IMMED\\_RETIRED](#).

**0x0079, BR\_RETURN\_SPEC, Branch speculatively executed, procedure return**

The counter counts procedure return instructions speculatively executed. Defined by the [BR\\_RETURN\\_RETIRED](#) event.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also [BR\\_RETURN\\_RETIRED](#).

**0x007A, BR\_INDIRECT\_SPEC, Branch speculatively executed, indirect branch**

The counter counts indirect branch instructions speculatively executed. This includes software change of the PC other than exception-generating instructions and immediate branch instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x007C, ISB\_SPEC, Barrier speculatively executed, ISB**

The counter counts Instruction Synchronization Barrier instructions speculatively executed, including [CP15ISB](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x007D, DSB\_SPEC, Barrier speculatively executed, DSB**

The counter counts data synchronization barrier instructions speculatively executed, including [CP15DSB](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x007E, DMB\_SPEC, Barrier speculatively executed, DMB**

The counter counts data memory barrier instructions speculatively executed, including [CP15DSB](#). It does not include the implied barrier operations of load/store operations with release consistency semantics.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x0081, EXC\_UNDEF, Exception taken, other synchronous**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only synchronous exceptions that are not counted by the other Exception taken events. This event counts only exceptions taken locally.

**0x0082, EXC\_SVC, Exception taken, Supervisor Call**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only Supervisor Call exceptions. This event counts only exceptions taken locally.

**0x0083, EXC\_PABORT, Exception taken, Instruction Abort**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only Instruction Abort exceptions. This event counts only exceptions taken locally.

**0x0084, EXC\_DABORT, Exception taken, Data Abort or SError**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only Data Abort or SError interrupt exceptions. The counter counts only exceptions taken locally.

**0x0086, EXC\_IRQ, Exception taken, IRQ**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only IRQ exceptions. The counter counts only exceptions taken locally, including Virtual IRQ exceptions.

**0x0087, EXC\_FIQ, Exception taken, FIQ**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only FIQ exceptions. The counter counts only exceptions taken locally, including Virtual FIQ exceptions.

**0x0088, EXC\_SMC, Exception taken, Secure Monitor Call**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only Secure Monitor Call exceptions. The counter does not increment on SMC instructions trapped as a Hyp Trap exception.

**0x008A, EXC\_HVC, Exception taken, Hypervisor Call**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only Hypervisor Call exceptions. The counter counts for both Hypervisor Call exceptions taken locally in the hypervisor and those taken as an exception from Non-secure EL1.

**0x008B, EXC\_TRAP\_PABORT, Exception taken, Instruction Abort not taken locally**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only Instruction Abort exceptions not taken locally.

**0x008C, EXC\_TRAP\_DABORT, Exception taken, Data Abort or SError not taken locally**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only Data Abort or SError interrupt exceptions not taken locally.

**0x008D, EXC\_TRAP\_OTHER, Exception taken, other traps not taken locally**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only those traps that are not counted as:

- Exception taken, Hypervisor Call.
- Exception taken, Instruction Abort not taken locally.
- Exception taken, Data Abort or SError not taken locally.
- Exception taken, IRQ not taken locally.
- Exception taken, FIQ not taken locally.

**0x008E, EXC\_TRAP\_IRQ, Exception taken, IRQ not taken locally**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only IRQ exceptions not taken locally.

**0x008F, EXC\_TRAP\_FIQ, Exception taken, FIQ not taken locally**

This event is similar to Exception taken, [EXC\\_TAKEN](#), but the counter counts only FIQ exceptions not taken locally.

**0x0090, RC\_LD\_SPEC, Release consistency operation speculatively executed, Load-Acquire**

The counter counts Load-Acquire operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x0091, RC\_ST\_SPEC, Release consistency operation speculatively executed, Store-Release**

The counter counts Store-Release operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x00A0, L3D\_CACHE\_RD, Attributable Level 3 data or unified cache access, read**

This event is similar to Attributable Level 3 data or unified cache access, [L3D\\_CACHE](#), but the counter counts only attributable memory read operations that cause a cache access to at least the Level 3 data or unified cache.

**0x00A1, L3D\_CACHE\_WR, Attributable Level 3 data or unified cache access, write**

This event is similar to Attributable Level 3 data or unified cache access, [L3D\\_CACHE](#), but the counter counts only attributable memory write operations that cause a cache access to at least the Level 3 data or unified cache.

**0x00A2, L3D\_CACHE\_REFILL\_RD, Attributable Level 3 data or unified cache refill, read**

This event is similar to Attributable Level 3 data or unified cache refill, [L3D\\_CACHE\\_REFILL](#), but the counter counts only attributable memory read operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3 cache. See also [Relationship between REFILL events and associated access events](#). on page K3-6165

**0x00A3, L3D\_CACHE\_REFILL\_WR, Attributable Level 3 data or unified cache refill, write**

This event is similar to Attributable Level 3 data or unified cache refill, [L3D\\_CACHE\\_REFILL](#), but the counter counts only attributable memory write operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3 cache. See also [Relationship between REFILL events and associated access events](#). on page K3-6165

**0x00A6, L3D\_CACHE\_WB\_VICTIM, Attributable Level 3 data or unified cache Write-Back, victim**

This event is similar to Attributable Level 3 data cache Write-Back, [L3D\\_CACHE\\_WB](#), but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

Write-Backs caused by the execution of a cache maintenance instruction are not counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

**0x00A7, L3D\_CACHE\_WB\_CLEAN, Level 3 data or unified cache Write-Back, cache clean**

This event is similar to Attributable Level 3 data cache Write-Back, [L3D\\_CACHE\\_WB](#), but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

**————— Note —————**

The transfer of a dirty cache line from the Level 3 data cache of this PE to the Level 3 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

**0x00A8, L3D\_CACHE\_INVALID, Attributable Level 3 data or unified cache access, invalidate**

The counter counts each invalidation of a cache line in the Level 3 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally-executed cache maintenance instructions that operate by set/way.

———— **Note** ————

Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

### K3.1.1 Relationship between REFILL events and associated access events.

CACHE\_REFILL and TLB\_REFILL events count the refills for accesses that are counted by the corresponding CACHE or TLB event. Table K3-2 shows this correspondence.

**Table K3-2 Relationship between REFILL events and associated access events**

REFILL event	Access event	Ratio REFILL/Access
0x0042 L1D_CACHE_REFILL_RD	0x0040 L1D_CACHE_RD	Attributable Level 1 cache refill rate, read
0x0043 L1D_CACHE_REFILL_WR	0x0041 L1D_CACHE_WR	Attributable Level 1 cache refill rate, write
0x004C L1D_TLB_REFILL_RD	0x004E L1D_TLB_RD	Attributable Level 1 TLB refill rate, read
0x004D L1D_TLB_REFILL_WR	0x004F L1D_TLB_WR	Attributable Level 1 TLB refill rate, write
0x0052 L2D_CACHE_REFILL_RD	0x0050 L2D_CACHE_RD	Attributable Level 2 data cache refill rate, read
0x0053 L2D_CACHE_REFILL_WR	0x0051 L2D_CACHE_WR	Attributable Level 2 data cache refill rate, write
0x005C L2D_TLB_REFILL_RD	0x005E L2D_TLB_RD	Attributable Level 2 data TLB refill rate, read
0x005D L2D_TLB_REFILL_WR	0x005F L2D_TLB_WR	Attributable Level 2 data TLB refill rate, write
0x00A2 L3D_CACHE_REFILL_RD	0x00A0 L3D_CACHE_RD	Attributable Level 3 data cache refill rate, read
0x00A3 L3D_CACHE_REFILL_WR	0x00A1 L3D_CACHE_WR	Attributable Level 3 data cache refill rate, write

## K3.2 Summary of events for exceptions taken to an Exception level using AArch64

Table K3-3 shows the events for exceptions taken to an Exception level using AArch64.

**Table K3-3 Events for exceptions taken to an Exception level using AArch64**

ESR.EC	Description	Event number and classification for exception taken to	
		EL1, or the current Exception level	EL2 or EL3, from below
0x00	Unknown or uncategorized	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x01	WFE/WFI traps	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x03	AArch32 MCR/MRC traps on (coproc==0b1111) accesses	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x04	AArch32 MCRR/MRRC traps on (coproc==0b1111) accesses	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x05	AArch32 MCR/MRC traps on (coproc==0b1110) accesses	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x06	AArch32 LDC/STC traps on (coproc==0b1110) accesses	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x07	Advanced SIMD or FP traps	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x08	AArch32 MVFR* and FPSID traps	-	0x008D, Other traps not taken locally
0x0C	AArch32 MCRR/MRRC traps on (coproc==0b1110) accesses	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x0E	Illegal instruction set state	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x11	AArch32 SVC	0x0082, Supervisor Call	0x008D, Other traps not taken locally
0x12	AArch32 HVC that is not disabled	-	0x008A, Hypervisor Call
0x13	AArch32 SMC that is not disabled	to EL2 -	0x008D, Other traps not taken locally
		to EL3 -	0x0088, Secure Monitor Call
0x15	AArch64 SVC	0x0082, Supervisor Call	0x008D, Other traps not taken locally
0x16	AArch64 HVC that is not disabled	0x008A, Hypervisor Call	0x008A, Hypervisor Call
0x17	AArch64 SMC that is not disabled	to EL2 -	0x008D, Other traps not taken locally
		to EL3 0x0088, Secure Monitor Call	0x0088, Secure Monitor Call

0x31	Breakpoint from current Exception level	0x0083, Instruction Abort	-
0x32	Software step from below	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
0x33	Software step from current Exception level	0x0083, Instruction Abort	-
0x34	Watchpoint from below	0x0084, Data Abort or SError	0x008C, Data Abort or SError not taken locally
0x35	Watchpoint from current Exception level	0x0084, Data Abort or SError	-
0x38	AArch32 BKPT instruction	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
0x3A	AArch32 Vector Catch debug event	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
0x3C	AArch64 BRK instruction	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
-	IRQ interrupt	0x0086, IRQ	0x008E, IRQ not taken locally
-	FIQ interrupt	0x0087, FIQ	0x008F, FIQ not taken locally

**Note**

In these definitions, an exception that is *taken locally* means an exception that is taken to the default Exception level, and is not routed to another Exception level. See [Exception levels on page D1-1776](#) for more information.

## Appendix K4

# Recommendations for reporting memory attributes on an interconnect

This appendix describes the ARM recommendations for reporting the memory attributes that are assigned by the PE. It contains the following section:

- [\*ARM recommendations for reporting memory attributes on an interconnect\*](#) on page K4-6170.

## K4.1 ARM recommendations for reporting memory attributes on an interconnect

The ARM architecture defines the architectural interface between software and the PE hardware. This means the mechanisms by which different memory type and Cacheability attributes are presented on an interface to an interconnect fabric such as AMBA® AXI are, strictly, outside the scope of the architecture. This appendix describes an approach for the interface between a PE implementation and an interconnect fabric that ARM strongly recommends, but these recommendations do not form part of the ARMv8 architecture.

### K4.1.1 Effect of microarchitectural choices on memory attributes

Implementations of the ARM architecture permit considerable variability in the presentation of memory attributes on the interconnect fabric, particularly in cases where the PE implementation does not provide optimized support for a memory type. For example, an implementation might treat Write-Through locations as Non-cacheable at some level of cache, because functionally this is consistent with the definition of Write-Through, but for the particular implementation the performance trade-off does not merit the hardware directly providing Write-Through capability. However, in such implementations, the assigned memory attributes are not changed by the microarchitectural choices. The microarchitecture simply implements different ways of handling some memory attributes.

Therefore, ARM strongly recommended that where any or all of the following memory attributes are presented on the interface between a PE and an interconnect fabric, the attributes that are presented are completely consistent with the attributes defined by the translation system:

- The memory type, Normal or Device.
- The Early write acknowledgement attribute.
- The ordering requirements.
- The Shareability.
- The Cacheability, including where practicable, the allocation hints.

#### Effect when memory accesses are forced to be Non-cacheable

ARM also strongly recommends that the effects of forcing accesses to Normal memory to be Non-cacheable, as described in [Enabling and disabling the caching of memory accesses on page D3-1978](#) for AArch64 and in [Enabling and disabling the caching of memory accesses in AArch32 state on page G3-4529](#) for AArch32, are reflected on the interconnect by the memory type and attributes used for memory transactions generated while the cache is disabled.

## Appendix K5

# Legacy Instruction Syntax for AArch32 Instruction Sets

This appendix describes the legacy instruction syntax in the ARM instruction sets, and their *Unified Assembler Language* (UAL) equivalents. It contains the following section:

- [Legacy Instruction Syntax on page K5-6172](#).

## K5.1 Legacy Instruction Syntax

Early versions of the ARM Architecture defined an assembly language for A32 (ARM) instructions, and a separate assembly language for T32 (Thumb) instructions. UAL is based on the A32 assembly language, with some changes to the instruction syntax. The appendix describes those changes. The pre-UAL mnemonics are compatible with UAL, and might be supported by an assembler.

The original T32 assembly language is not compatible with UAL, and is not described in the manual.

### K5.1.1 Pre-UAL instruction syntax for the A32 base instructions

Table K5-1 lists the syntax for the A32 base instructions that have changed after UAL was introduced.

**Table K5-1 Pre-UAL instruction syntax for the A32 base instructions**

### K5.1.3 FCONST

The syntax of FCONST is

FCONST<dest>{<c>} <Fd>, #<imm8>

where:

- |        |  |
|--------|--|
| <dest> | Specifies the destination data type. It must be one of:<br>S .           Single-precision floating-point.<br>D .           Double-precision floating-point.  |
| <c>    | This is an optional field. It specifies the condition under which the instruction is executed. See <a href="#">Conditional execution on page F2-2849</a> for the range of available conditions and their encoding. If <c> is omitted, it defaults to <i>always</i> (AL). |
| <Fd>   | Specifies the destination register. It must be one of:<br><Dd>         64-bit name of the SIMD&FP destination register.<br><Sd>         32-bit name of the SMID&FP destination register.   |
| <imm8> | Specifies the immediate value used to generate the floating-point constant.  |
- FCONSTD{<c>} <Dd>, #<imm8> maps to VMOV.F64 <Dd>, #<fpimm>
- FCONSTS{<c>} <Sd>, #<imm8> maps to VMOV.F32 <Sd>, #<fpimm>

# Appendix K6

## Address translation examples

This appendix gives examples of address translations using the translation regimes described in [Chapter D4 The AArch64 Virtual Memory System Architecture](#) and [Chapter G4 The AArch32 Virtual Memory System Architecture](#). It contains the following sections:

- [AArch64 Address translation examples](#) on page K6-6180.
- [AArch32 Address translation examples](#) on page K6-6193.

### ———— **Note** —————

This chapter gives examples of translation table lookups for the ARMv8 address translation stages. It does not define any part of the address translation mechanism. If any information in this appendix appears to contradict the information in [Chapter D4 The AArch64 Virtual Memory System Architecture](#) or [Chapter G4 The AArch32 Virtual Memory System Architecture](#) then the information in [Chapter D4](#) or [Chapter G4](#) must be taken as the definition of the required behavior.

## K6.1 AArch64 Address translation examples

Figure D4-1 on page D4-2009 shows the VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64. *The VMSAv8-64 address translation system on page D4-2008* describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

*System registers relevant to MMU operation on page D4-2014* specifies the relevant registers, including the `TCR_ELx` and `TTBR_ELx`, or `TTBR_ELxs`, for each stage of address translation.

For any stage of translation, a `TCR_ELx.TnSZ` field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is  $2^{(64-TnSZ)}$ .

This section describes:

- Performing the initial lookup, for an address for which the initial lookup is either:
  - At the highest lookup level used for the appropriate translation granule size.
  - Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

These descriptions take account of the following cases:

- The IA size is smaller than the largest size for the translation level, see *Reduced IA width on page D4-2025*.
- For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see *Concatenated translation tables on page D4-2025*.

For examples of performing the initial lookup, see *Examples of performing the initial lookup*.

- The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see *Full translation flows for VMSAv8-64 address translation on page K6-6187*.

### K6.1.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

- *Performing the initial lookup using the 4KB translation granule*.
- *Performing the initial lookup using the 16KB granule on page K6-6183*.
- *Performing the initial lookup using the 64KB translation granule on page K6-6185*.

#### Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that *Table D4-13 on page D4-2031* shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system on page D4-2008*.

#### ————— Note —————

For stage 2 translations, the same principles apply to an initial lookup that *Table D4-13 on page D4-2031* shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 4KB translation granule on page K6-6181*.
- *Initial lookup at level 1, 4KB translation granule on page K6-6181*.

In all cases, for a stage 2 translation, the `VTCTR_EL2.SL0` field must indicate the required initial lookup level, and this level must be consistent with the value of the `VTCTR_EL2.T0SZ` field, see *Overview of stage 2 translations, 4KB granule on page D4-2031*.

### Initial lookup at level 0, 4KB translation granule

This subsection describes initial lookups with an input address width of  $(n+1)$  bits, meaning the input address is  $IA[n:0]$ . As Table D4-13 on page D4-2031 shows, a stage 1 or stage 2 initial lookup at level 0 is required when  $39 \leq n \leq 47$ . For these lookups:

- $TTBR\_ELx[47:(n-35)]$  specify the translation table base address.
- Bits  $[n:39]$  of the input address are bits  $[(n-36):3]$  of the descriptor offset in the translation table.

#### ———— Note ————

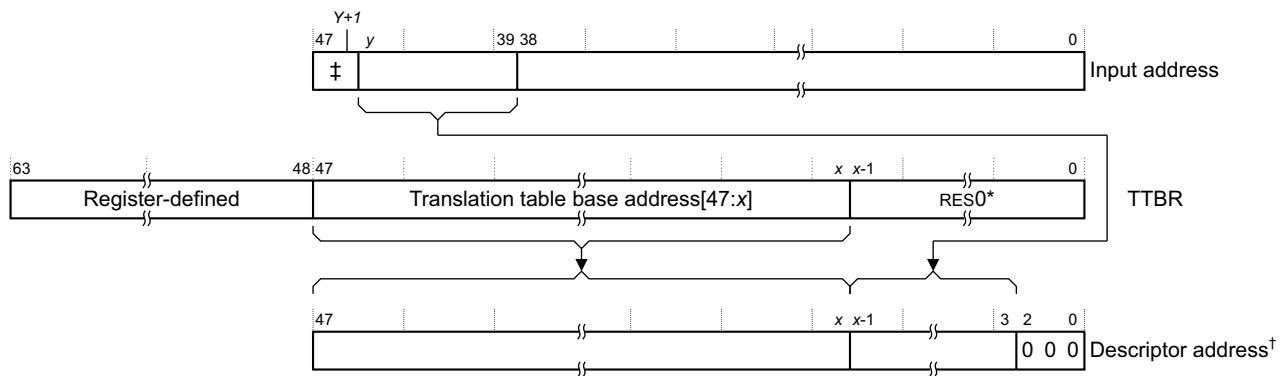

**This means that, when the input address width is less than 48 bits**

- The size of the translation table is reduced.
- More low-order bits of the  $TTBR\_ELx$  are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB,
- $TTBR\_ELx$  bits  $[47:10]$  specify the translation table base address.
- Input address bits  $[45:39]$  specify bits  $[9:3]$  of the descriptor offset.

Figure K6-1 shows this lookup.

Supported input address range is  $IA[y:0]$ ,  $4 \leq x \leq 12$ ,  $y = x + 35$ . When  $y$  is 47 the field marked † is absent.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

\* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K6-1 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 0**

### Initial lookup at level 1, 4KB translation granule

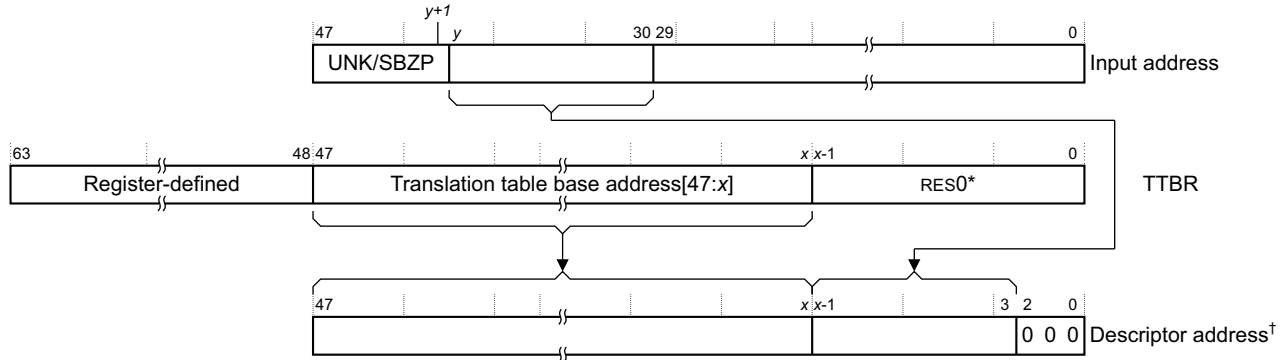

This subsection describes initial lookups with an input address width of  $(n+1)$  bits, meaning the input address is  $IA[n:0]$ .

#### For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D4-13 on page D4-2031 shows, this applies to  $IA[n:0]$ , where  $30 \leq n \leq 38$ . For these lookups:

- There is a single translation table at this level.
- $TTBR\_ELx[47:(n-26)]$  specify the translation table base address.
- Bits  $[n:30]$  of the input address are bits  $[(n-27):3]$  of the descriptor offset in the translation table.

Figure K6-2 on page K6-6182 shows this lookup.

Supported input address range is  $IA[y:0]$ ,  $4 \leq x \leq 12$ ,  $y = x + 26$ .

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

\* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K6-2 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, without concatenation**

**For a stage 2 initial lookup at level 1, with concatenated translation tables**

As Table D4-13 on page D4-2031 shows, this applies to  $IA[n:0]$ , where  $39 \leq n \leq 42$ . For these lookups:

- There are  $2^{(n-38)}$  concatenated translation tables at this level.
- These concatenated translation tables must be aligned to  $2^{(n-38)} \times 4\text{KB}$ . This means  $TTBR\_ELx[(n-27):12]$  must be zero.
- $TTBR\_ELx[47:(n-26)]$  specify the base address of the block of concatenated translation tables.
- Bits  $[n:30]$  of the input address are bits  $[(n-27):3]$  of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K6-3 shows this lookup.

Supported input address range is  $IPA[y:0]$ ,  $4 \leq x \leq 16$ ,  $y = x + 26$ . The field marked ‡ must be zero.

\* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K6-3 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, with concatenation**

## Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that [Table D4-16 on page D4-2035](#) shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system on page D4-2008*.

### ———— Note ————

For stage 2 translations, the same principles apply to an initial lookup that [Table D4-16 on page D4-2035](#) shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- [Initial lookup at level 0, 16KB translation granule.](#)
- [Initial lookup at level 1, 16KB translation granule on page K6-6184.](#)

In all cases, for a stage 2 translation, the `VTCR_EL2.SL0` field must indicate the required initial lookup level, and this level must be consistent with the value of the `VTCR_EL2.T0SZ` field, see [Overview of stage 2 translations, 16KB granule on page D4-2035](#).

### Initial lookup at level 0, 16KB translation granule

This subsection describes initial lookups with an input address width of  $(n+1)$  bits, meaning the input address is `IA[n:0]`. As [Table D4-15 on page D4-2034](#) shows, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, `IA[47:0]`. For this lookup:

- The required translation table has only two entries, meaning its size is 16bytes, and it must be aligned to 16 bytes.
- `TTBR_ELx[47:4]` specify the translation table base address.
- Bit[47] of the input address is bits[3] of the descriptor offset in the translation table.

[Figure K6-4](#) shows this lookup.

Supported input address range is `IA[47:0]`. The field marked ‡ is `RES0*`.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

\* Field has additional properties to the default `RES0` definition, see the register description for more information.

**Figure K6-4 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 0**

### Initial lookup at level 1, 16KB translation granule

This subsection describes initial lookups with an input address width of  $(n+1)$  bits, meaning the input address is  $IA[n:0]$ .

#### For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D4-16 on page D4-2035 shows, this applies to  $IA[n:0]$ , where  $36 \leq n \leq 46$ . For these lookups:

- There is a single translation table at this level.
- $TTBR\_ELx[47:(n-32)]$  specify the translation table base address.
- Bits  $[n:36]$  of the input address are bits  $[(n-33):3]$  of the descriptor offset in the translation table.

Figure K6-5 shows this lookup.

Supported input address range is  $IA[y:0]$ ,  $4 \leq x \leq 14$ ,  $y = x + 32$ .

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

\* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K6-5 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, without concatenation**

#### For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D4-16 on page D4-2035 shows, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address,  $IA[47:0]$ . For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to  $2 \times 16KB$ . This means  $TTBR\_ELx[14]$  must be zero.
- $TTBR\_ELx[47:15]$  specify the base address of the block of two concatenated translation tables.
- Bits  $[47:36]$  of the input address are bits  $[14:3]$  of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K6-6 on page K6-6185 shows this lookup.

Supported input address range is IPA[47:0]. The bit marked ‡ must be zero.

\* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K6-6 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, with concatenation**

### Performing the initial lookup using the 64KB translation granule

This subsection describes examples of the initial lookup when using the 64KB translation granule that [Table D4-19 on page D4-2039](#) shows as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in [The VMSAv8-64 address translation system on page D4-2008](#).

#### Note

For stage 2 translations, the same principles apply to an initial lookup that [Table D4-19 on page D4-2039](#) shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

The following subsections describe these examples of the initial lookup:

- [Initial lookup at level 1, 64KB translation granule.](#)
- [Initial lookup at level 2, 64KB translation granule on page K6-6186.](#)

In all cases, for a stage 2 translation, the [VTCR\\_EL2.SL0](#) field must indicate the required initial lookup level, and this level must be consistent with the value of the [VTCR\\_EL2.T0SZ](#) field, see [Overview of stage 2 translations, 64KB granule on page D4-2039](#).

#### Initial lookup at level 1, 64KB translation granule

This subsection describes initial lookups with an input address width of  $(n+1)$  bits, meaning the input address is  $IA[n:0]$ . As [Table D4-19 on page D4-2039](#) shows, a stage 1 or stage 2 initial lookup at level 1 is required when  $42 \leq n \leq 47$ . For these lookups:

- The size of the translation table is  $2^{(n-39)}$  bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits  $[n:42]$  of the input address are bits  $[(n-39):3]$  of the descriptor offset in the translation table.
- Bits  $[47:(n-38)]$  of the [TTBR\\_ELx](#) specify the translation table base address.

[Figure K6-7 on page K6-6186](#) shows this lookup.

Supported input address range is  $IA[y:0]$ ,  $4 \leq x \leq 9$ ,  $y = x + 38$ . When  $y$  is 47 the field marked † is absent.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

\* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K6-7 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 1**

### Initial lookup at level 2, 64KB translation granule

This subsection describes initial lookups with an input address width of  $(n+1)$  bits, meaning the input address is  $IA[n:0]$ .

#### For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As Table D4-19 on page D4-2039 shows, this applies to  $IA[n:0]$ , where  $29 \leq n \leq 41$ . For these lookups:

- There is a single translation table at this level.
- $TTBR\_ELx[47:(n-25)]$  of the specify the translation table base address.
- Bits  $[n:29]$  of the input address are bits  $[(n-26):3]$  of the descriptor offset in the translation table.

Figure K6-8 shows this lookup.

Supported input address range is  $IA[y:0]$ ,  $4 \leq x \leq 16$ ,  $y = x + 25$ .

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

\* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K6-8 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, without concatenation**

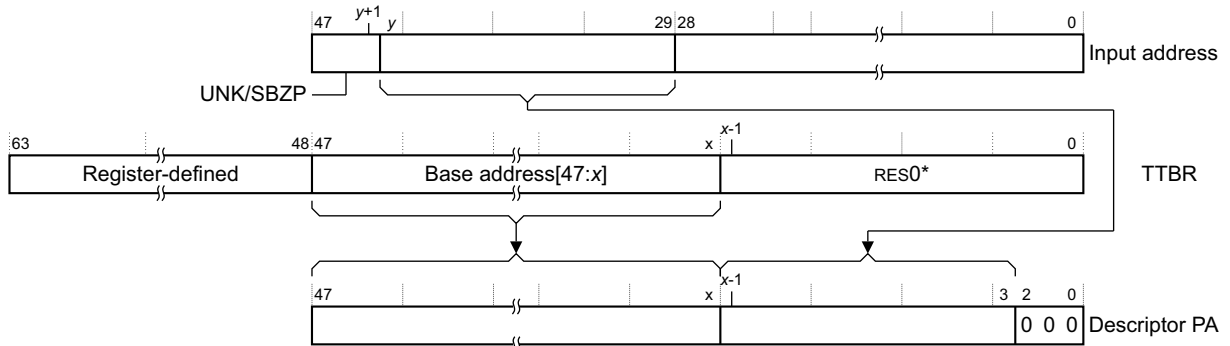

**For a stage 2 initial lookup at level 2, with concatenated translation tables**

As Table D4-19 on page D4-2039 shows, this applies to  $IA[n:0]$ , where  $42 \leq n \leq 45$ . For these lookups:

- There are  $2^{(m-41)}$  concatenated translation tables at this level.
- These concatenated translation tables must be aligned to  $2^{(m-41)} \times 64\text{KB}$ . This means  $TTBR\_ELx[(n-26):16]$  must be zero.
- $TTBR\_ELx[47:(n-25)]$  specify the base address of the block of translation tables.
- Bits  $[n:42]$  of the input address are bits  $[(n-26):16]$  of the descriptor offset from the base address of the block of translation tables.

Figure K6-9 shows this lookup.

Supported input address range is  $IPA[y:0]$ ,  $4 \leq x \leq 20$ ,  $y = x + 25$ .

\* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K6-9 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation**

## K6.1.2 Full translation flows for VMSAv8-64 address translation

In a translation table walk, only the first lookup uses the translation table base address from the appropriate  $TTBR\_ELx$ . Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section describes example full translation flows, from the initial lookup to the address of a memory page. The example flows:

- Resolve the maximum-sized IA range supported by the initial lookup level.
- Do not have any concatenation of translation tables.
- Cover only the 4KB and the 64KB translation granules.

*Examples of performing the initial lookup on page K6-6180* described how either reducing the IA range or concatenating translation tables affects the initial lookup.

### **Note**

Reducing the IA range or concatenating translation tables affects only the initial lookup.

The following sections describe full VMSAv8-64 translation flows, down to an entry for a memory page:

- *The address and properties fields shown in the translation flows on page K6-6188.*
- *Full translation flow using the 4KB granule and starting at level 0 on page K6-6189.*
- *Full translation flow using the 4KB granule and starting at level 1 on page K6-6190.*
- *Full translation flow using the 64KB granule and starting at level 1 on page K6-6191.*
- *Full translation flow using the 64KB granule and starting at level 2 on page K6-6192.*

### The address and properties fields shown in the translation flows

For the Non-secure EL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

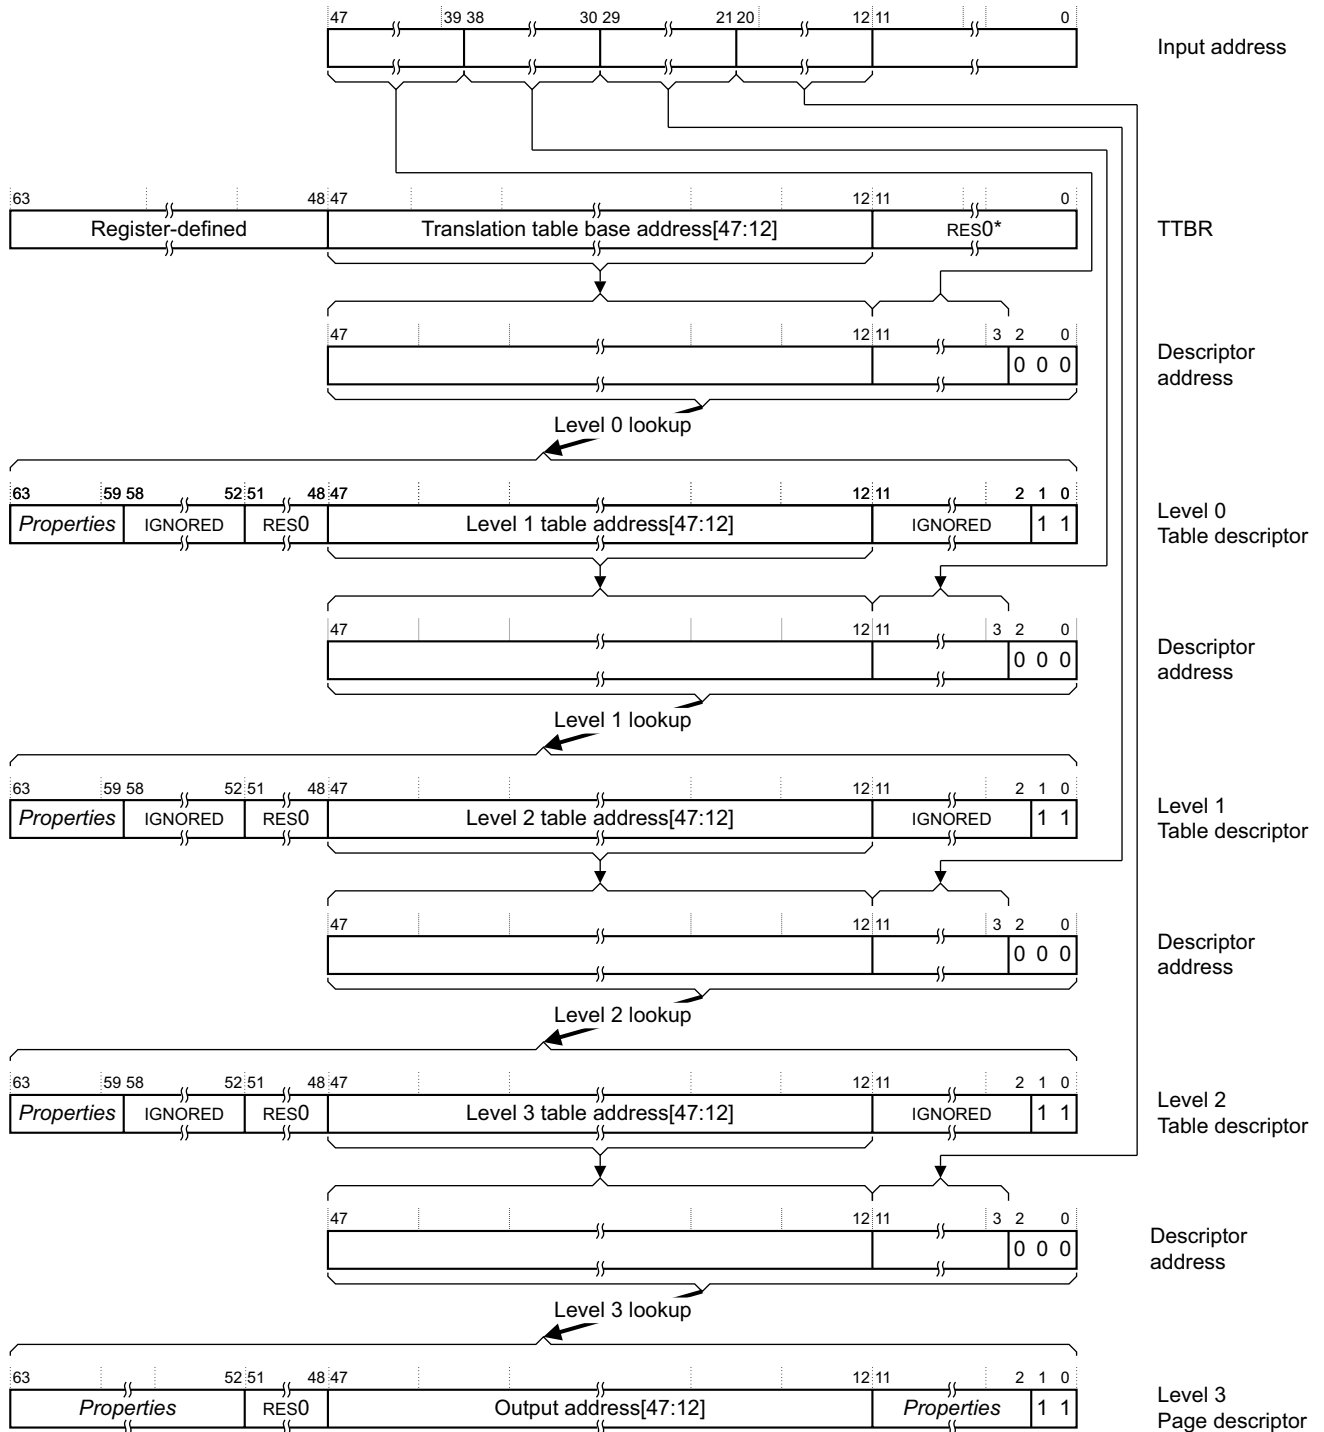

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-2064](#).

## Full translation flow using the 4KB granule and starting at level 0

Figure K6-10 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K6-6188.

**Figure K6-10 Complete stage 1 translation of a 48-bit address using the 4KB translation granule**

If the level 1 lookup or level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K6-10 on page K6-6189 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

### Full translation flow using the 4KB granule and starting at level 1

Figure K6-11 shows the complete translation flow for a stage 1 translation table walk for a 39-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K6-6188.

For details of *Properties* fields, see the register or descriptor description.

\* Field has additional properties to the default RES0 definition, see the register description for more information.

**Figure K6-11 Complete stage 1 translation of a 39-bit address using the 4KB translation granule**

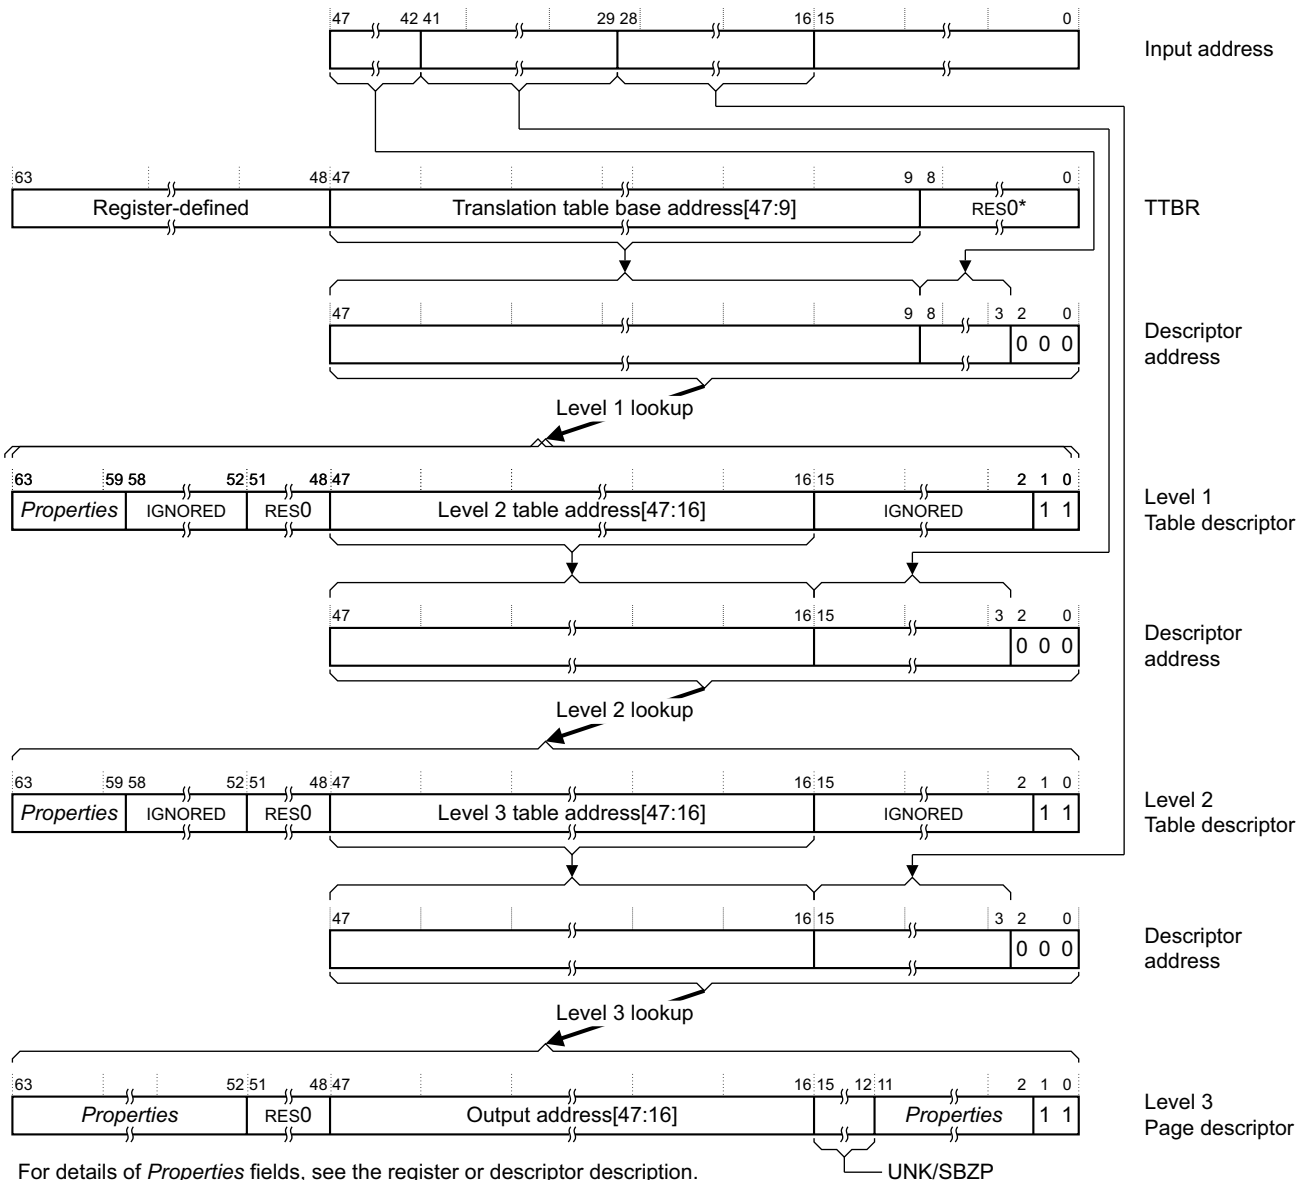

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K6-11 on page K6-6190 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K6-10 on page K6-6189, shows how the translation for the 42-bit address start the same lookup process one stage later.

### Full translation flow using the 64KB granule and starting at level 1

Figure K6-10 on page K6-6189 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows on page K6-6188*.

**Figure K6-12 Complete stage 1 translation of a 48-bit address using the 64KB translation granule**

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

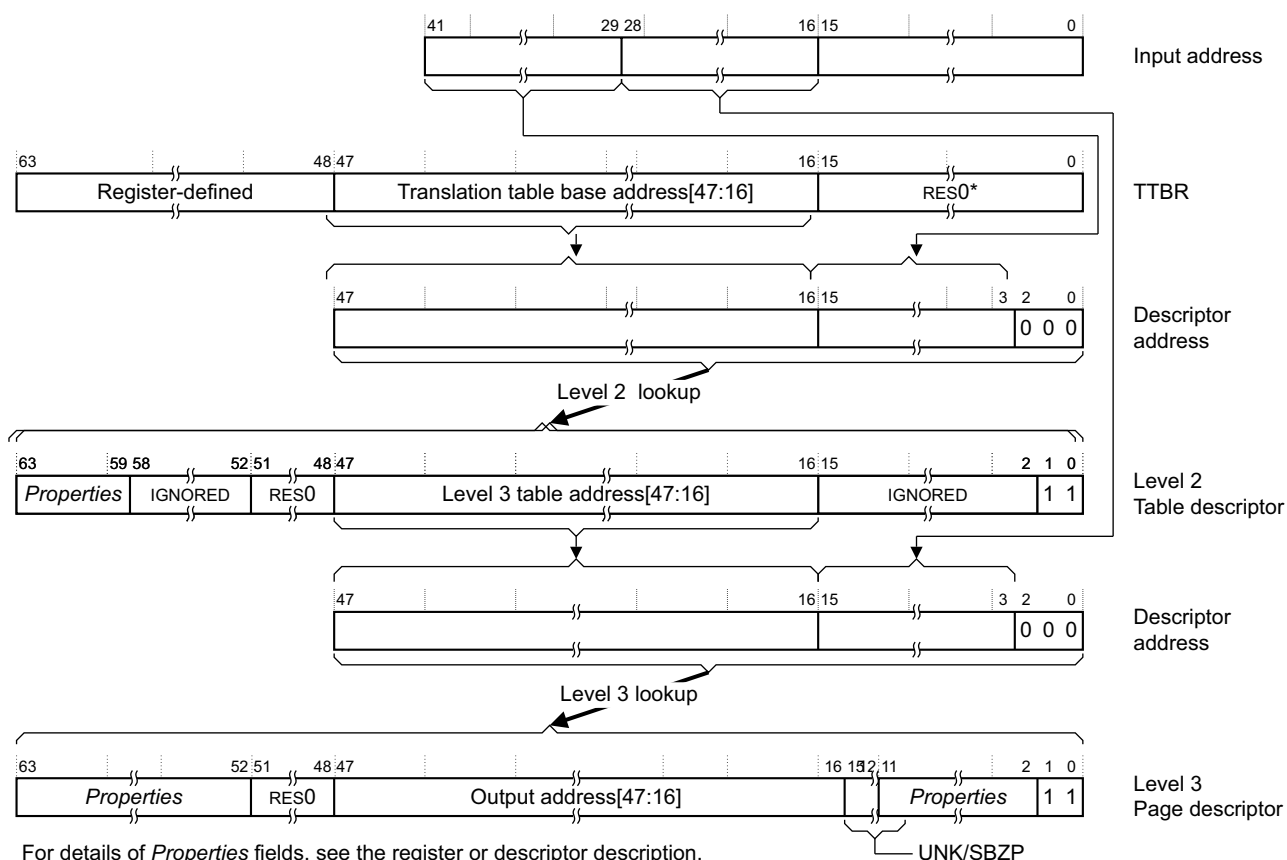

Figure K6-12 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

The level 1 lookup resolves only 6 bits of the input address. As described in [Performing the initial lookup using the 64KB translation granule on page K6-6185](#), this means:

- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the **TTBR\_ELx** is extended, at the low-order end, to be bits[47:9].

### Full translation flow using the 64KB granule and starting at level 2

Figure K6-11 on page K6-6190 shows the complete translation flow for a stage 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure see [The address and properties fields shown in the translation flows on page K6-6188](#).

### Figure K6-13 Complete stage 1 translation of a 42-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K6-13 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K6-12 on page K6-6191, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
  - The translation table size for this level is 64KB.
  - The required translation table alignment for this level is 64KB.
  - The Base address field in the **TTBR\_ELx** is bits[47:16].

## K6.2 AArch32 Address translation examples

The following sections give address translation examples for the VMSSAv8-32 address translation formats:

- [Address translation examples using the VMSSAv8-32 Short descriptor translation table format.](#)
- [Address translation examples using the VMSSAv8-32 Long descriptor translation table format on page K6-6198.](#)

### K6.2.1 Address translation examples using the VMSSAv8-32 Short descriptor translation table format

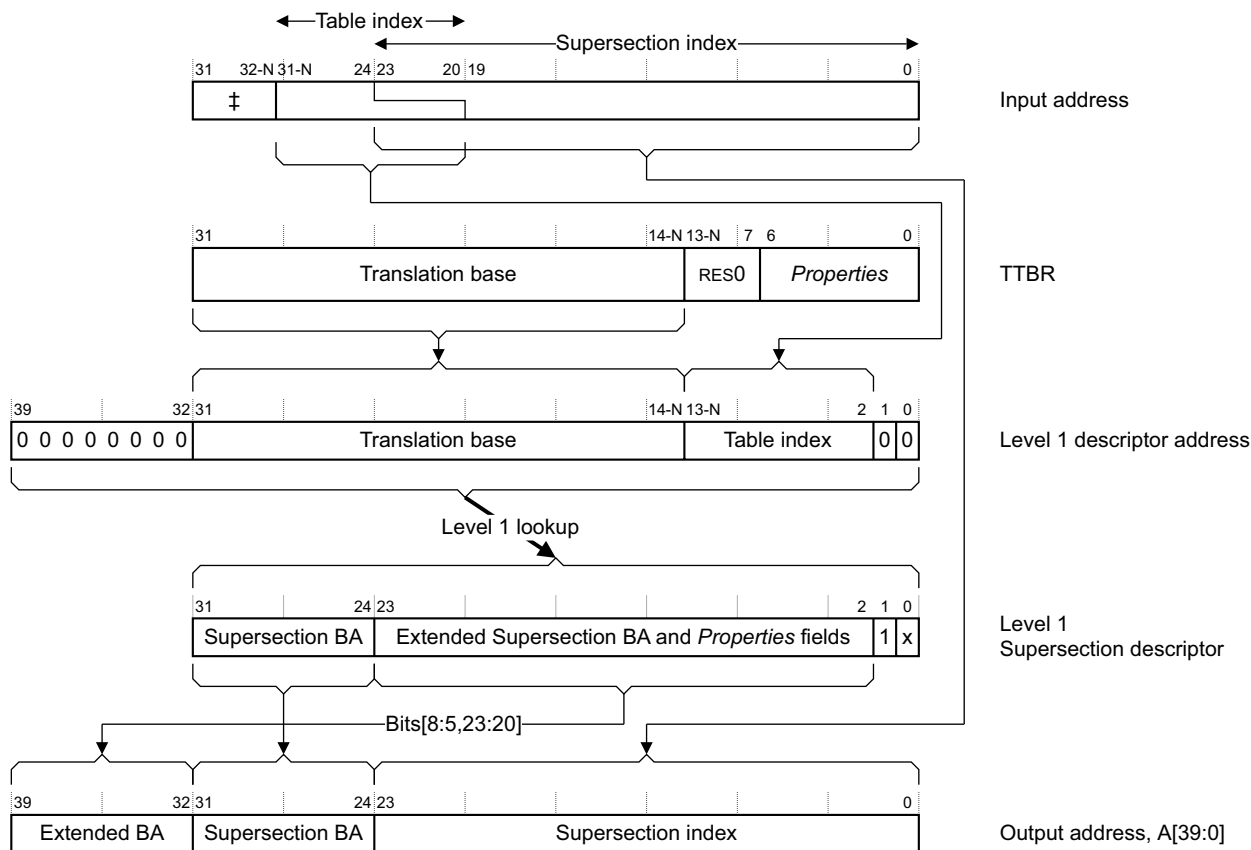

[VMSSAv8-32 Short-descriptor translation table format descriptors on page G4-4577](#) describes the memory section and page option for a single VMSSAv8-32 address translation. The following sections show the full translation flow for each of these options:

- [Translation flow for a Supersection on page K6-6194.](#)
- [Translation flow for a Section on page K6-6195.](#)
- [Translation flow for a Large page on page K6-6196.](#)
- [Translation flow for a Small page on page K6-6197.](#)

[The address and Properties fields shown in the translation flows on page K6-6198](#) summarizes the information returned by the lookup.

## Translation flow for a Supersection

Figure K6-14 shows the complete translation flow for a Supersection. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows on page K6-6198*.

‡ This field is absent if N is 0

BA = Base address

For a translation based on TTBR0, N is the value of TTBCR.N

For a translation based on TTBR1, N is 0

For details of *Properties* fields, see the register or descriptor description

**Figure K6-14 VMSAv8-32 Short-descriptor Supersection address translation**

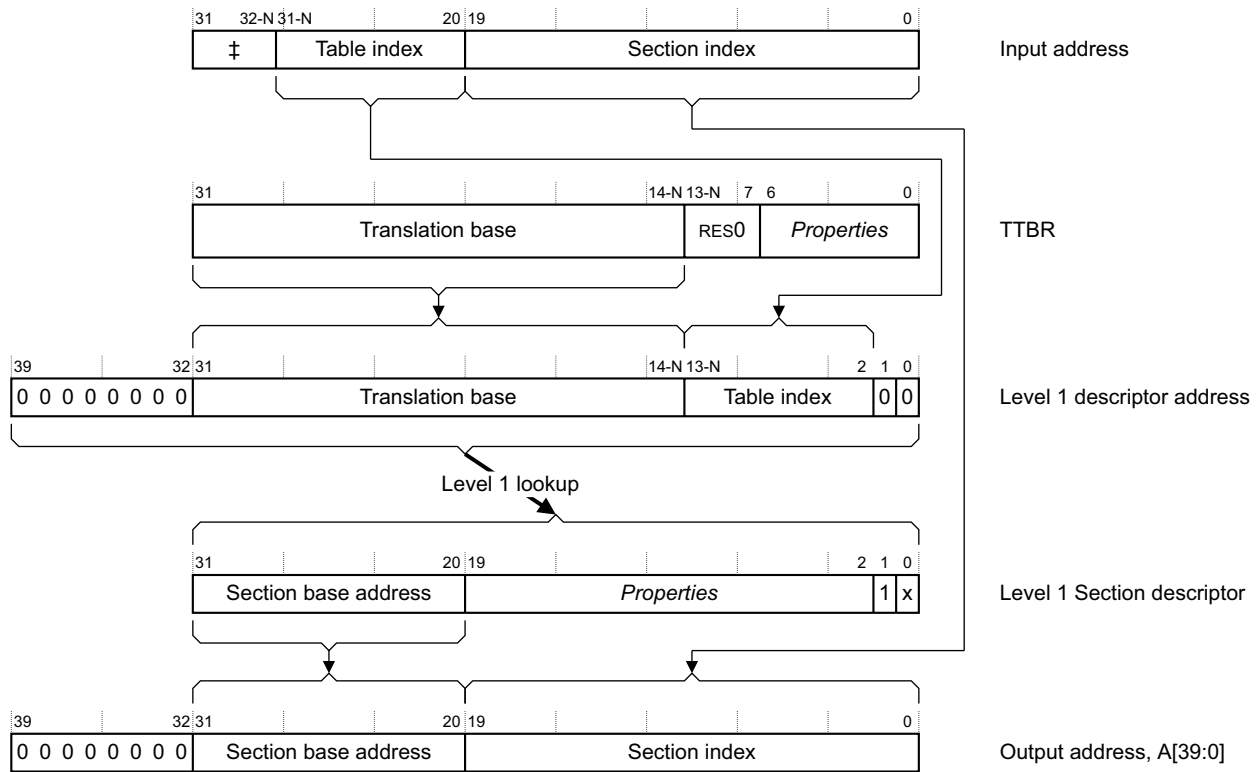

### Note

Figure K6-14 shows how, when the input address, the VA, addresses a Supersection, the top four bits of the *Supersection index* bits of the address overlap the bottom four bits of the *Table index* bits. For more information, see *Additional requirements for Short-descriptor format translation tables on page G4-4580*.

## Translation flow for a Section

Figure K6-15 shows the complete translation flow for a Section. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows on page K6-6198*.

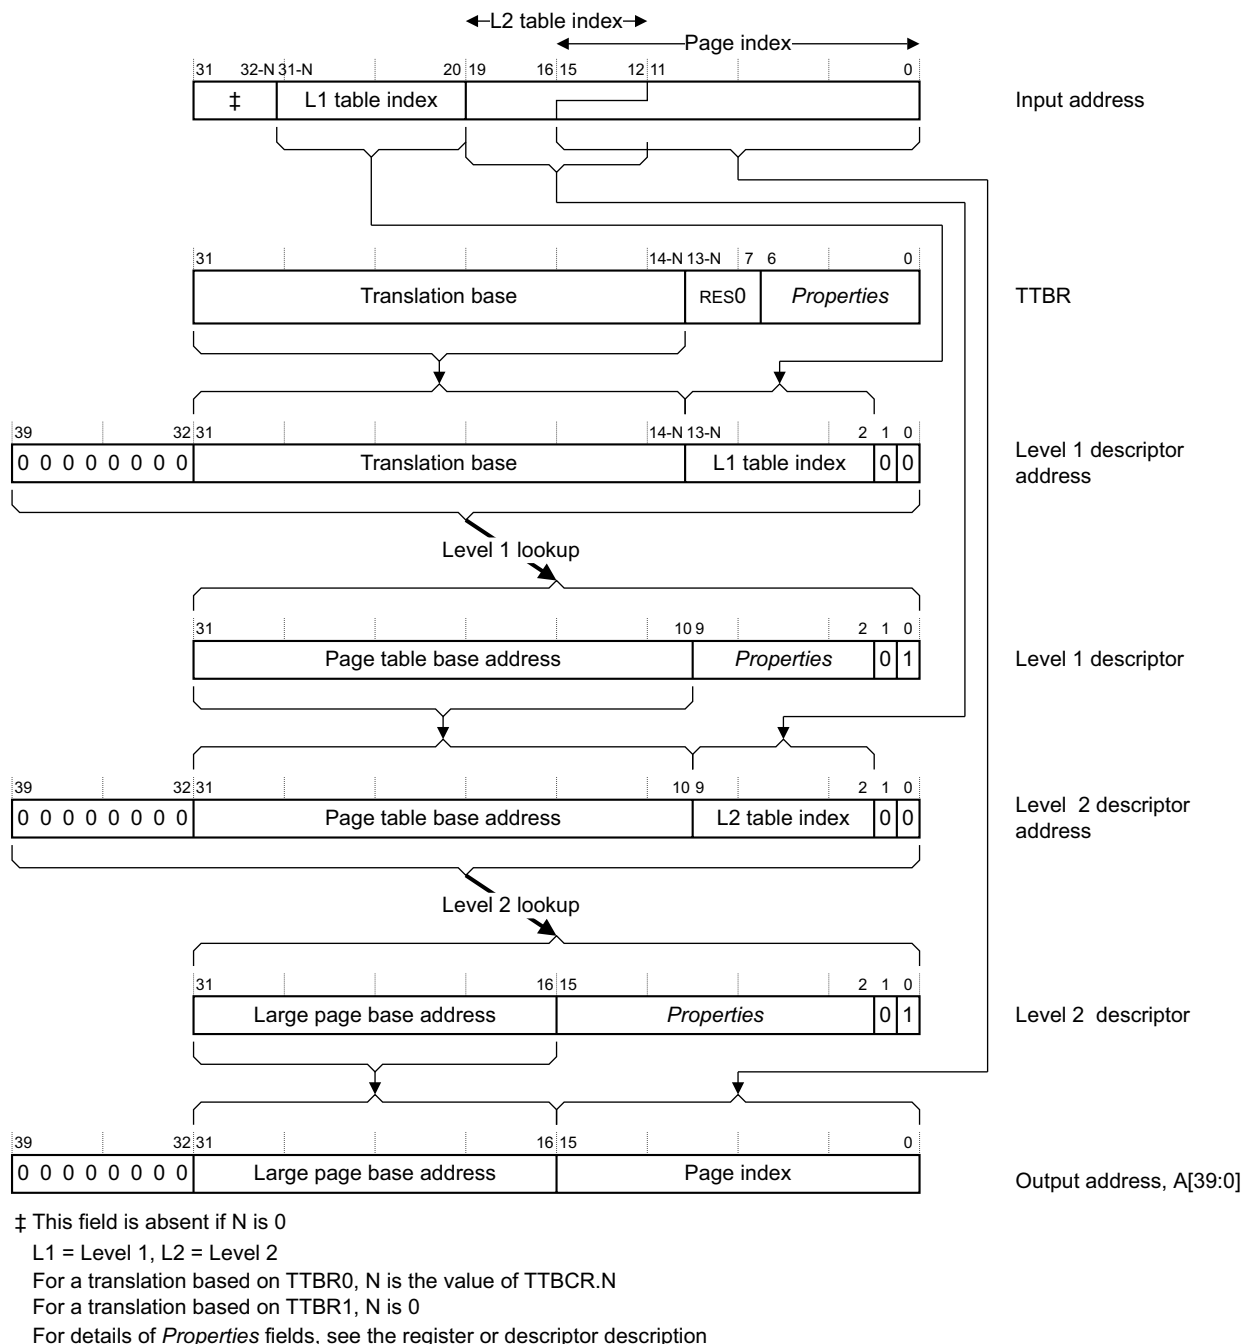

$\ddagger$  This field is absent if N is 0  
For a translation based on TTBR0, N is the value of TTBCR.N  
For a translation based on TTBR1, N is 0  
For details of *Properties* fields, see the register or descriptor description.

Figure K6-15 VMSAv8-32 Short-descriptor Section address translation

## Translation flow for a Large page

Figure K6-16 shows the complete translation flow for a Large page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows on page K6-6198*.

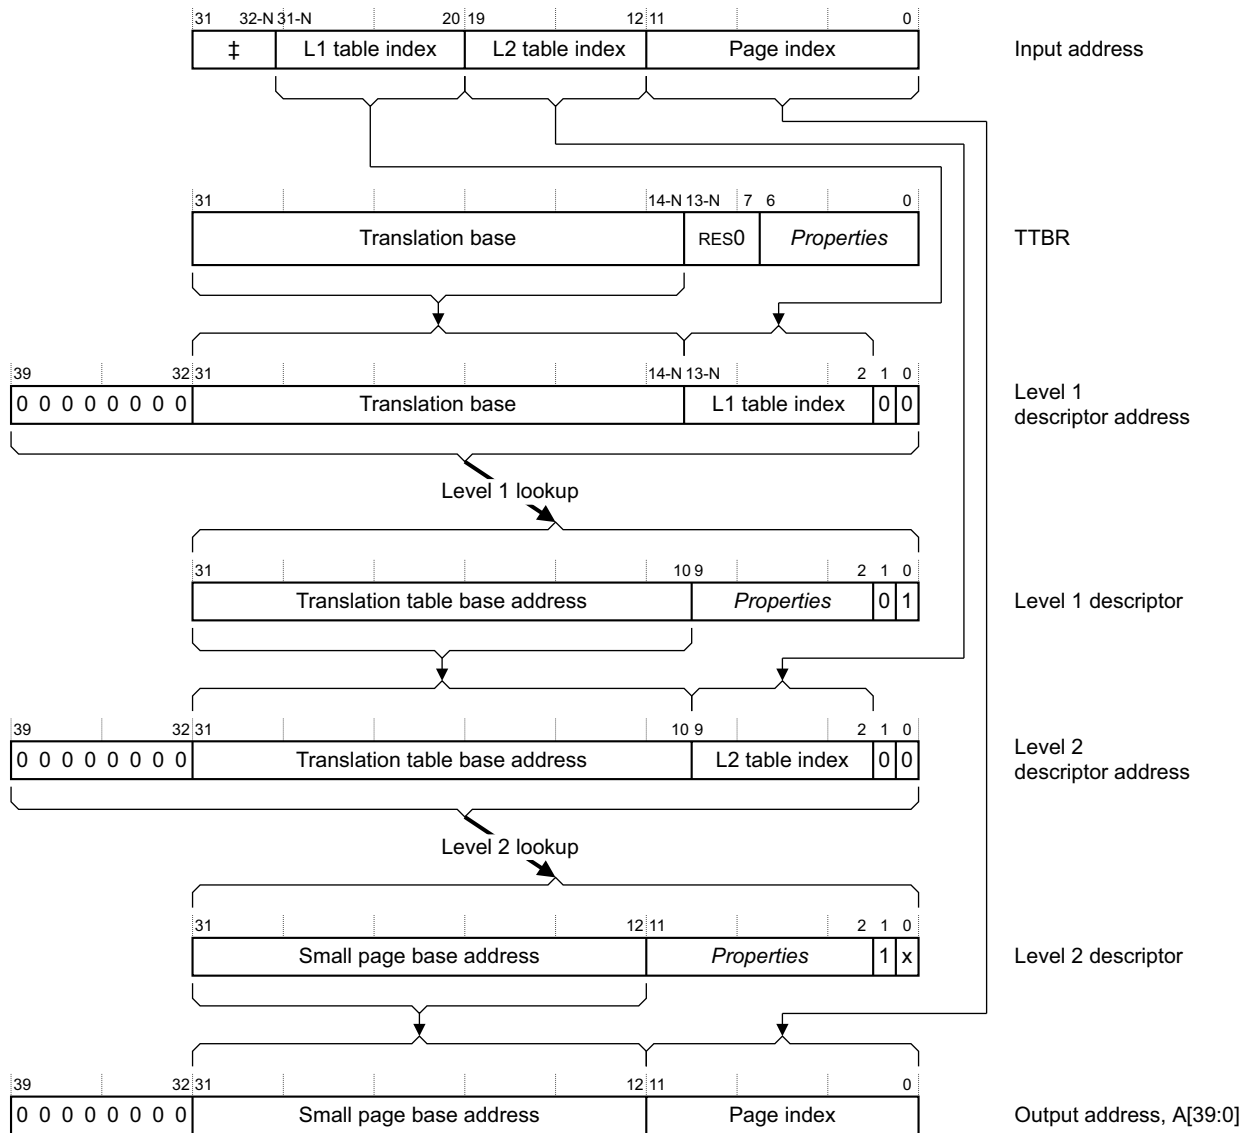

**Figure K6-16 VMSAv8-32 Short-descriptor Large page address translation**

### Note

Figure K6-16 shows how, when the input address, the VA, addresses a Large page, the top four bits of the *page index* bits of the address overlap the bottom four bits of the *level 1 table index* bits. For more information, see *Additional requirements for Short-descriptor format translation tables on page G4-4580*.

## Translation flow for a Small page

Figure K6-17 shows the complete translation flow for a Small page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows on page K6-6198*.

$\ddagger$  This field is absent if N is 0  
L1 = Level 1, L2 = Level 2  
For a translation based on TTBR0, N is the value of TTBCR.N  
For a translation based on TTBR1, N is 0  
For details of *Properties* fields, see the register or descriptor description.

**Figure K6-17 VMSAv8-32 Short-descriptor Small page address translation**

### The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation tables:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Information returned by a translation table lookup on page G4-4572](#), and the description of the register or translation table descriptor.

For translations using the Short-descriptor translation table format, [VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4577](#) describes the descriptors formats.

## K6.2.2 Address translation examples using the VMSAv8-32 Long descriptor translation table format

As described in [Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G4-4600](#), in a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

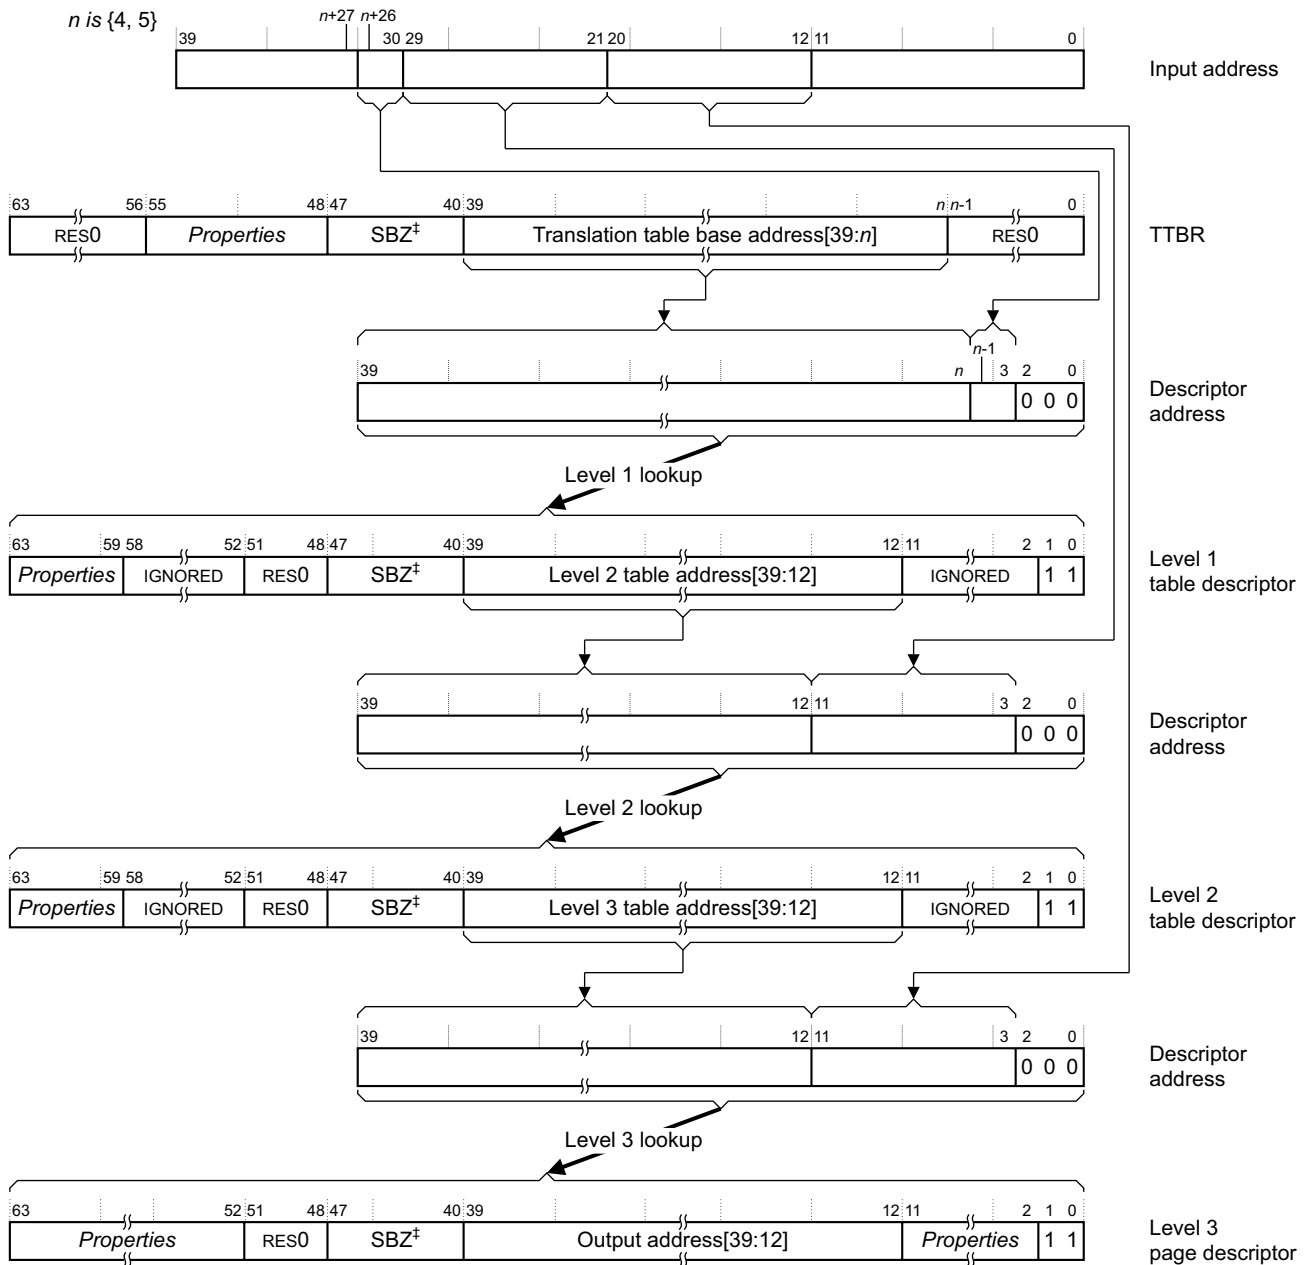

The following sections give examples of full VMSAv8-32 Long-descriptor format address translation flows, down to an entry for a 4KB page:

- [Full translation flow, starting at level 1 lookup on page K6-6199](#).
- [Full translation flow, starting at level 2 lookup on page K6-6200](#).

[The address and Properties fields shown in the translation flows](#) summarizes the information returned by the lookup.

## Full translation flow, starting at level 1 lookup

Figure K6-18 shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a level 1 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page K6-6198.

For details of *Properties* fields, see the register or descriptor description.

‡ See the lookup description for more information about bits[40:47] of the TTBR and descriptors

### Figure K6-18 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 1

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

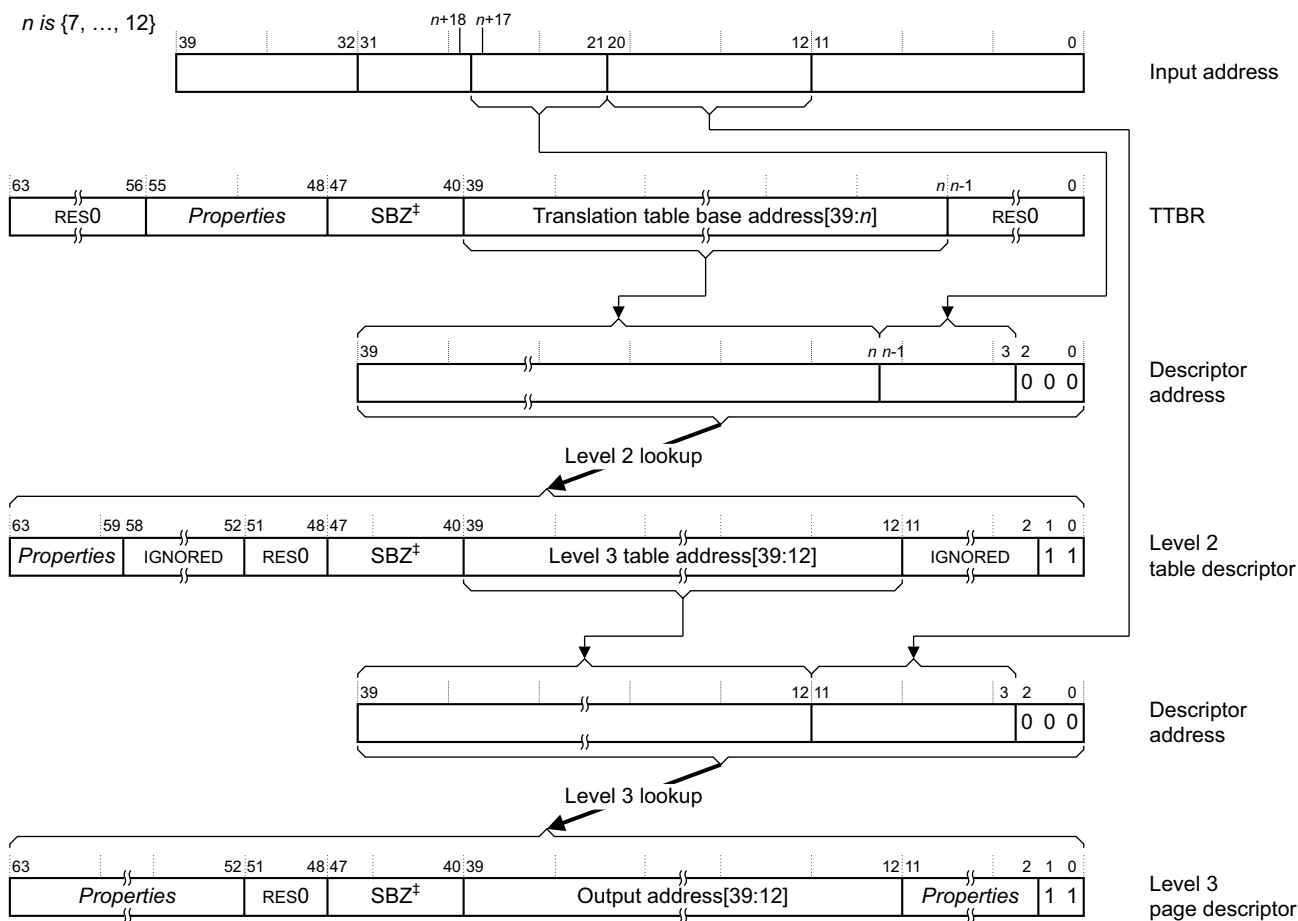

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see *Address size fault* on page G4-4658.

A stage 2 translation that starts at a level 1 lookup differs from the translation shown in [Figure K6-18 on page K6-6199](#) only as follows:

- The possible values of  $n$  are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.

### Full translation flow, starting at level 2 lookup

[Figure K6-19](#) shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a level 2 lookup. For more information about the fields shown in the figure see [The address and Properties fields shown in the translation flows on page K6-6198](#).

For details of *Properties* fields, see the register or descriptor description.

<sup>‡</sup> See the lookup description for more information about bits[40:47] of the TTBR and descriptors

### Figure K6-19 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 2

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the [TTBR](#) or the descriptor are not zero then the lookup will generate an Address size fault, see [Address size fault on page G4-4658](#).

A stage 2 translation that starts at a level 2 lookup differs from the translation shown in [Figure K6-19](#) only as follows:

- The possible values of  $n$  are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.

## The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Information returned by a translation table lookup on page G4-4572](#), and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, [VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4586](#) describes the descriptors formats.

## Appendix K7

# Example OS Save and Restore Sequences

This appendix provides possible OS Save and Restore sequences for a v8 Debug implementation. It contains the following sections:

- [Save Debug registers on page K7-6204.](#)
- [Restore Debug registers on page K7-6206.](#)

## K7.1 Save Debug registers

This section shows how to save the registers that are used by an external debugger.

; On entry, X0 points to a block to save the debug registers in.  
; Returns the pointer beyond the block and corrupts X1-X3

SaveDebugRegisters

```
; (1) Set OS lock.
MOV    X2,#1                ; Set the OS lock. In AArch64 state, the OS lock
MSR    OSLAR_EL1,X2         ; is writable via OSLAR.
ISB                                ; Context synchronization event
```

```
; (2) Walk through the registers, saving them
MRS    X1,OSDTRRX_EL1       ; Read DTRRX
MRS    X2,OSDTRTX_EL1       ; Read DTRTX
STP    W1,W2,[X0],#8        ; Save { DTRRX, DTRTX }
MRS    X1,OSECCR_EL1         ; Read ECCR
MRS    X2,MDSCR_EL1         ; Read DSCR
STP    W1,W2,[X0],#8        ; Save { ECCR, DSCR }
[ AARCH32_SUPPORTED
MRS    X1,DBGVCR32_EL2       ; Read DBGVCR
MRS    X2,DBGCLAIMCLR_EL1    ; Read CLAIM - note, have to read via CLAIMCLR
STP    W1,W2,[X0],#8        ; Save { VCR, CLAIM }
]
```

```
;; Macros for saving off a "register pair"
;; $WB      is W for watchpoint, B for breakpoint
;; $num      is the pair's number
;; X0 contains a pointer for the value words
;; X1 contains a pointer for the control words
;; W2 contains the max index
```

```
MACRO
SaveRP $WB,$num, $exit
MRS    X3,DBG$WB.VR$num._EL1 ; Read DBGxVRn
STR    X3,[X0],#8            ; Save { xVRn }
MRS    X3,DBG$WB.CR$num._EL1 ; Read DBGxCrN
STR    W3,[X0],#4            ; Save { xCRn }.
[ $num > 1 :LAND: $num < 15
CMP    W1,$num
BEQ    $exit
]
MEND
```

```
; (3) Breakpoints
MRS    X1,ID_AA64DFR0_EL1
UBFX    W1,W1,#12,#4        ; Extract BRPs field
MACRO
SaveBRP $num                ; Save a Breakpoint Register Pair
SaveRP B,$num,SaveDebugRegisters_Watchpoints
MEND
SaveBRP 0
SaveBRP 1
SaveBRP 2
;; and so on to ...
SaveBRP 15
```

SaveDebugRegisters\_Watchpoints

```
; (4) Watchpoints
MRS    X1,ID_AA64DFR0_EL1    ; Read DBGDIDR
UBFX    W1,W1,#20,#4        ; Extract WRPs field
MACRO
SaveWRP $num                ; Save a Watchpoint Register Pair
SaveRP W,$num,SaveDebugRegisters_Exit
MEND
SaveWRP 0
SaveWRP 1
SaveWRP 2
```

```
;; and so on to ...  
SaveWRP 15  
  
SaveDebugRegisters_Exit  
; (5) Return the pointer to first word not read. This pointer is already in X0, so  
; all that is needed is to return from this function. The OS double-lock (OSDLR_EL1.DLK) is  
; locked later, just before the final entry to WFI state.  
RET
```

## K7.2 Restore Debug registers

This section shows how to restore the registers that are used by an external debugger.

; On entry, X0 points to a block of saved debug registers.  
; Returns the pointer beyond the block and corrupts R1-R3,R12.

```
RestoreDebugRegisters
; (1) Lock OS lock. The lock will already be set, but this write is included to ensure it
; is locked.
MOV    X2,#1                ; Lock the OS lock. In AArch64 state, the OS lock
MSR    OSLAR_EL1,X2         ; is writable via OSLAR.
ISB                                ; Context synchronization event

MSR    MDSCR_EL1, XZR        ; Initialize MDSCR_EL1

; (2) Walk through the registers, restoring them
LDP    W1,W2,[X0],#8         ; Read { DTRRX,DTRTX }
MSR    OSDTRRX_EL1,X1        ; Restore DTRRX
MSR    OSDTRTX_EL1,X2        ; Restore DTRTX
LDP    W1,W3,[X0],#8         ; Read { DSCR, ECCR }
MSR    OSECCR_EL1,X2         ; Restore ECCR
[ AARCH32_SUPPORTED
LDP    W1,W2,[X0],#8         ; Read { VCR,CLAIM }
MSR    DBGVCR32_EL2,X1       ; Restore DBGVCR
MSR    DBGCLAIMSET_EL1,X2    ; Restore CLAIM - note, writes CLAIMSET
]

;; Macro for restoring a "register pair"
MACRO
RestoreRP $WB,$num,$exit
LDR    X3,[X0],#8            ; Read { xVRn }
MSR    DBG$WB.VR$num._EL1,X3 ; Restore DBGxVRn
LDR    W3,[X0],#4            ; Read { xCRn }
MSR    DBG$WB.CR$num._EL1,X3 ; Restore DBGxCRn
[ $num >= 1 :LAND: $num < 15
CMP    W1,$num
BEQ    $exit
]
MEND

; (3) Breakpoints
MRS    X1,ID_AA64DFR0_EL1
UBFX   W1,W1,#12,#4          ; Extract BRPs field
MACRO
RestoreBRP $num                ; Restore a Breakpoint Register Pair
RestoreRP B,$num,RestoreDebugRegisters_Watchpoints
MEND
RestoreBRP 0
RestoreBRP 1
RestoreBRP 2
;; and so on until ...
RestoreBRP 15

RestoreDebugRegisters_Watchpoints
; (4) Watchpoints
MRS    X1,ID_AA64DFR0_EL1    ; Read DBGDIDR
UBFX   W1,W1,#20,#4          ; Extract WRPs field
MACRO

RestoreWRP 15
```

```
RestoreDebugRegisters_Exit
    MSR MDSCR_EL1, X3                ; Restore DSCR

    ; (5) Clear the OS lock.
    ISB
    MOV     X2, #0                    ; Clear the OS lock. In AArch64 state, the OS lock
    MSR     OSLAR_EL1, X2             ; is writable via OSLAR.

    ; (6) A final ISB guarantees the restored register values are visible to subsequent
    ; instructions.
    ISB

    ; (7) Return the pointer to first word not read. This pointer is already in X0, so
    ; all that is needed is to return from this function.
    RET
```

## Appendix K8

# Recommended Upload and Download Processes for External Debug

This appendix contains the following section:

- [Using memory access mode in AArch64 state on page K8-6210.](#)

---

### **Note**

---

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.

---

## K8.1 Using memory access mode in AArch64 state

Figure K8-1 and Figure K8-2 on page K8-6211 show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer  $n$  words of data:

- The download sequence needs  $n+6$  accesses by the external debug interface.
- The upload sequence needs  $n+8$  accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling `EDSCR` after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the `EDSCR.ERR` flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the `EDSCR.ERR` flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in `X0`. `EDSCR.ERR` might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

### Note

- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

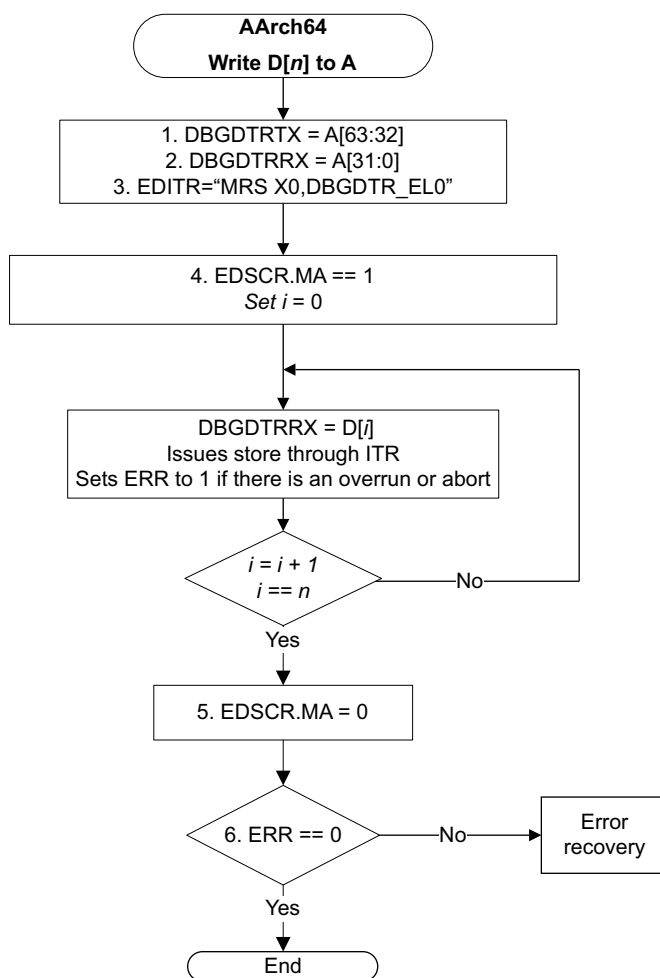

Figure K8-1 Fast code download in AArch64 state (external host to target)

In Figure K8-1 on page K8-6210, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
  - a. Write address [31:0] to `DBGDTRRX_EL0`.
  - b. Write address [63:32] to `DBGDTRTX_EL0`.
  - c. Write MRS `X0`, `DBGDTR_EL0` to `EDITR`. The PE executes this instruction.
  - d. Set `EDSCR.MA` to 1.
2. Loop  $n$  times. From the external debug interface:
  - a. Write to `DBGDTRRX_EL0`. The PE reads the word from `DTRRX` and stores it to memory. It increments `X0` by 4.
3. Epilogue. From the external debug interface:
  - a. Clear `EDSCR.MA` to 0.
  - b. Read `EDSCR` to check for overruns or Data Aborts during download.

Figure K8-2 Fast data upload in AArch64 state (target to external host)

In Figure K8-2 on page K8-6211, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
  - a. Write address [31:0] to `DBGDTRRX_EL0`.
  - b. Write address [63:32] to `DBGDTRTX_EL0`.
  - c. Write MRS `X0`, `DBGDTR_EL0` to `EDITR`.
  - d. Write MSR `DBGDTR_EL0`, `X0` to `EDITR`. This dummy operation ensures `EDSCR.TXfull == 1`.
  - e. Set `EDSCR.MA` to 1.
  - f. Read `DBGDTRTX_EL0` and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments `X0` by 4.
2. Loop  $n-1$  times. From the external debug interface:
  - a. Read `DBGDTRTX_EL0`. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments `X0` by 4.
3. Epilogue. From the external debug interface:
  - a. Clear `EDSCR.MA` to 0.
  - b. Read `DBGDTRTX_EL0` for the  $n^{\text{th}}$  value.
  - c. Read `EDSCR` to check for underruns, overruns or Data Aborts during upload.

## Appendix K9

# Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the ARMv8 architecture. It contains the following sections:

- [Introduction on page K9-6214.](#)
- [Load-Acquire, Store-Release and barriers on page K9-6217.](#)
- [Load-Acquire Exclusive, Store-Release Exclusive and barriers on page K9-6221.](#)
- [Using a mailbox to send an interrupt on page K9-6226.](#)
- [Cache and TLB maintenance instructions and barriers on page K9-6227.](#)
- [ARMv7 compatible approaches for ordering, using DMB and DSB barriers on page K9-6239.](#)

---

### **Note**

This information is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

---

## K9.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the ARMv8 architecture.

This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

### K9.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the *Sequential Execution Model* (SEM), and in this Manual it is described as *Simple sequential execution* of the program.

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as ARM, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the ARM architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to System registers.

In both these cases, the ISB instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate with memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of *memory consistency*. Processor architectures have adopted one or more *memory consistency models*, or *memory models*, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and ARM recommends the *Memory Consistency Models for Shared Memory-Multiprocessors* paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the ARM architecture from ARMv6. In particular, the examples show how the use of the DMB and DSB memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

### K9.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

**DMB** See [Data Memory Barrier \(DMB\)](#) on page B2-92.

**DSB** See [Data Synchronization Barrier \(DSB\)](#) on page B2-93.

**ISB** See [Instruction Synchronization Barrier \(ISB\)](#) on page B2-92.

#### Observer, Completion

See [Definition of the ARMv8 memory model](#) on page B2-86.

See [Completion and endpoint ordering](#) on page B2-91.

## Program order

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

### K9.1.3 Conventions

Many of the examples are written in a stylized extension to ARM assembler, to avoid confusing the examples with unnecessary code sequences.

#### AArch32

The construct `WAIT([Rx]==1)` describes the following sequence:

```
loop
    LDR R12, [Rx]
    CMP R12, #1
    BNE loop
```

Also, the construct `WAIT_ACQ([Rx]==1)` describes the following sequence:

```
loop
    LDA R12, [Rx]      ; load acquire ensures it is ordered before subsequent loads/stores
    CMP R12, #1
    BNE loop
```

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

#### AArch64

The construct `WAIT([Xx]==1)` describes the following sequence:

```
loop
    LDR W12, [Xx]
    CMP W12, #1
    B.NE loop
```

Also, the construct `WAIT_ACQ([Xx]==1)` and describes the following sequence:

```
loop
    LDAR W12, [Xx]      ; load acquire ensures it is ordered before subsequent loads/stores
    CMP W12, #1
    B.NE loop
```

For each example, a code sequence is preceded by an identifier of the observer running it:

- P0, P1...Px refer to caching coherent PEs that implement the ARMv8 architecture, and are in the same shareability domain.
- E0, E1...Ex refer to non-caching observers, that do not participate in the coherency protocol, but execute ARM instructions and have a weakly-ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system masters.

These observers are unsynchronized other than as required by the documented code sequence.

#### ————— Note —————

Throughout this appendix, *ARM instruction* and *instruction* refer to instructions from the A64, A32, or T32 instruction set, provided by ARMv8 implementations.

Results are expressed in terms of <agent>:<register>, such as P0:R5. The results can be described as:

<b>Permissible</b>	This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues.
<b>Not permissible</b>	Results that the architecture expressly forbids.
<b>Required</b>	Results that the architecture expressly requires.

The examples omit the required shareability domain arguments of DMB and DSB instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a DMB ST, that is a barrier to stores only, this is shown by the use of DMB [ST]. This indicates that the ST qualifier can be omitted without affecting the result of the test. In some implementations DMB ST is faster than DMB.

For AArch64 code, the shareability domain of the DMB or DSB must be included. This is shown in this manual using the notation DMB <domain> and DSB <domain> respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- R0 and W0 contain the value 1.
- R1 - R4 and W1 - W4 contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are shareable and:
  - The addresses held in R1 and R2 are in Write-Back Cacheable Normal memory.
  - The address held in R3 is in Write-Through Cacheable Normal memory.
  - The address held in R4 is in Non-cacheable Normal memory.
- R5 - R8 and W5 - W8 contain:
  - When used with an STR instruction, 0x55, 0x66, 0x77, and 0x88 respectively.
  - When used with an LDR instruction, the value 0.
- R11 and W11 contain a new instruction or new translation table entry, as appropriate, and R10 contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance instructions. The following tables describe the mnemonics:

- [Cache maintenance instructions, functional group on page G4-4734.](#)
- [TLB maintenance instructions, functional group on page G4-4735.](#)

## K9.2 Load-Acquire, Store-Release and barriers

The Load-Acquire and Store-Release instructions are described in [Load-Acquire, Store-Release](#) on page B2-94.

The following sections show that most of the examples in sections [Simple ordering and barrier cases](#) on page K9-6239 and [Load-Exclusive, Store-Exclusive and barriers](#) on page K9-6243 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

### K9.2.1 Message passing

The following sections describe:

- [Resolving weakly-ordered message passing by using Acquire and Release.](#)
- [Resolving message passing by the use of Store-Release and address dependency](#) on page K9-6218.

#### Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in [Weakly-ordered message passing problem](#) on page K9-6239 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

##### AArch32

P1

```
STR R5, [R1]      ; sets new data
STL R0, [R2]      ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([R2]==1) ; waits on flag
LDR R5, [R1]
```

##### AArch64

P1

```
STR W5, [X1]      ; sets new data
STLR W0, [X2]     ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([X2]==1) ; waits on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2:R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

##### AArch32

P3

```
WAIT_ACQ([R2]==1) ; waits on flag
LDR R5, [R1]
```

##### AArch64

P3

```
WAIT_ACQ([X2]==1) ; waits on flag
LDR W5, [X1]
```

## Resolving message passing by the use of Store-Release and address dependency

The lack of ordering of stores discussed in [Message passing with multiple observers on page K9-6241](#) can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

### AArch32

P1

```
STR R5, [R1]          ; sets new data
STL R0, [R2]          ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
                     : and so is ordered after the flag has been seen
```

### AArch64

P1

```
STR W5, [X1]          ; sets new data
STLR W0, [X2]         ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([X2]==1)
AND W12, W12, WZR     ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
                     : and so is ordered after the flag has been seen
```

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of 0x55.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

### AArch32

P3

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
                     : and so is ordered after the flag has been seen
```

### AArch64

P3

```
WAIT([X2]==1)
AND W12, W12, WZR     ; R12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
                     : and so is ordered after the flag has been seen
```

## K9.2.2 Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

### AArch32

P1

```
STR R5, [R1, #offset] ; sets new data in a field
STL R1, [R2]           ; updates base address
```

P2

```
LDR R1, [R2]           ; reads base address
CMP R1, #0             ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field
```

### AArch64

P1

```
STR W5, [X1, #offset] ; sets new data in a field
STLR X1, [X2]          ; updates base address
```

P2

```
LDR X1, [X2]           ; reads base address
CMP X1, #0             ; check if it is valid
B.EQ null_trap
LDR W5, [X1, #offset] ; uses base address to read field
```

It is required that  $P2:R5 \neq 0x55$  if the `null_trap` is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.

### K9.2.3 WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit DSB barrier instruction is required if it is necessary to ensure memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in [Posting a store before polling for acknowledgement on page K9-6242](#), or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

#### AArch32

```
P1
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

#### AArch64

```
P1
    STR W0, [X2]
    DSB <domain>
Loop
    WFI
    B Loop
```

This requirement is unchanged in ARMv8 by the presence of Load-Acquire or Store-Release.

## K9.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The ARMv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

- No Ordering semantics (using LDREX and STREX).
- Acquire only semantics (using LDAEX and STREX).
- Release only semantics (using LDREX and STLEX).
- Sequentially consistent semantics (using LDAEX and STLEX).

In addition, the ARMv8 specification requires that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of WFE, by removing the need for a DSB barrier and SEV instruction.

### K9.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

#### AArch32

Px

```

    PLDW[R1]          ; preload into cache in unique state
Loop
    LDAEX R5, [R1]     ; read lock with acquire
    CMP R5, #0         ; check if 0
    STREXEQ R5, R0, [R1] ; attempt to store new value
    CMPEQ R5, #0       ; test if store succeeded
    BNE Loop          ; retry if not

    ; loads and stores in the critical region can now be performed

```

#### AArch64

Px

```

    PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop
    LDAXR W5, [X1]       ; read lock with acquire
    CBNZ W5, Loop        ; check if 0
    STXR W5, W0, [X1]    ; attempt to store new value
    CBNZ W5, Loop        ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed

```

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.

## K9.3.2 Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

### AArch32

Px

```
; loads and stores in the critical region
MOV R0, #0
STL R0, [R1]          ; clear the lock with release semantics
```

### AArch64

Px

```
; loads and stores in the critical region
STLR WZR, [X1]        ; clear the lock with release semantics
```

## K9.3.3 Ticket locks

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

### ———— Note ————

The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.

This is shown in the implementation below:

### AArch32

Px

```
; R1 holds two 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

    PLDW[R1]          ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]    ; read current and next
    ADD R5, R5, #0x10000 ; increment the next number
    STREX R6, R5, [R1] ; and update the value
    CMP R6, #0        ; did the exclusive pass
    BNE Loop1         ; retry if not
    CMP R5, R5, ROR #16 ; is the current ticket ours
    BEQ block_start
Loop2
    LDAH R6, [R1]     ; read current value
    CMP R6, R5, LSR #16 ; compare it with our allocated ticket
    BNE Loop2         ; retry (spin) if it is not the same
block_start
```

## AArch64

Px

```

; X1 holds 2 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop1
LDAXR W5, [X1] ; read current and next
ADD W5, W5, #0x10000 ; increment the next number
STXR W6, W5, [X1] ; and update the value
CBNZ W6, Loop1 ; did the exclusive pass - retry if not

AND W6, W5, #0xFFFF
CMP W6, W5, LSR #16 ; is the current ticket ours
B.EQ block_start
Loop2
LDARH W6, [X1] ; read current value
CMP W6, W5, LSR #16 ; compare it with the our allocated ticket
B.NE Loop2 ; retry (spin) if it isn't the same
block_start

```

Releasing the ticket lock simply involves incrementing the current ticket number, that is still assumed to be in R3, and doing a Store-Release:

## AArch32

```

ADD R6, R6, #1
STLH R6, [R1]

```

## AArch64

```

ADD W6, W6, #1
STLRH W6, [X1]

```

### K9.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture can use the Wait For Event mechanism to minimise the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In ARMv8, the event can be generated as a result of clearing the global monitor, so removing the need for a DSB barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

#### Simple lock

The following is an example of lock acquire code using WFE:

## AArch32

Px

```

PLDW[R1] ; preload into cache in unique state
Loop
LDAEX R5, [R1] ; read lock with acquire
CMP R5, #0 ; check if 0
WFENE ; sleep if the lock is held
STREXEQ R5, R0, [R1] ; attempt to store new value
CMPEQ R5, #0 ; test if store succeeded
BNE Loop ; retry if not

```

#### AArch64

Px

```

    SEVL                ; invalidates the WFE on the first loop iteration
    PRFM PSTL1KEEP, [X1] ; allocate into cache in unique state
Loop
    WFE
    LDAXR W5, [X1]       ; read lock with acquire
    CBNZ W5, Loop        ; check if 0
    STXR W5, W0, [X1]    ; attempt to store new value
    CBNZ W5, Loop        ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed

```

And the following is an example of lock release code:

#### AArch32

Px

```

    ; loads and stores in the critical region
    MOV R0, #0
    STL R0, [R1]         ; clear the lock

```

#### AArch64

Px

```

    ; loads and stores in the critical region
    STLR WZR, [X1]       ; clear the lock

```

#### Ticket lock

In the Ticket lock case, the Load-Exclusive instruction can be used to move the monitor into the exclusive state for the express purpose of creating an event when the monitor changes state:

#### AArch32

Px

```

    ; R1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PLDW[R1]            ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]      ; read current and next
    ADD R5, R5, #0x10000 ; increment the next number
    STREX R6, R5, [R1]  ; and update the value
    CMP R6, #0          ; did the exclusive pass
    BNE Loop            ; retry if not
    CMP R5, R5, ROR #16 ; is the current ticket ours
    BEQ block_start
    SEVL
Loop2
    WFE                ; wait if there has not been a change to the count since last
                        ; read
    LDAEXH R6, [R1]     ; check the current count
    CMP R6, R5, LSR #16 ; check if it is equal
    BNE Loop2
block_start

```

## AArch64

Px

```
    ; X1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop1
    LDAXR W5, [X1]        ; read current and next
    ADD W5, W5, #0x10000  ; increment the next number
    STXR W6, W5, [X1]     ; and update the value
    CBNZ W6, Loop1        ; did the exclusive pass - retry if not

    AND W6, W5, 0xFFFF
    CMP W6, W5, LSR #16   ; is the current ticket ours
    B.EQ block_start
    SEVL
Loop2
    WFE
    LDAXRH W6, [X1]       ; read current value
    CMP W6, W5, LSR #16   ; compare it with our allocated ticket
    B.NE Loop2            ; retry (spin) if it is not the same
block_start
```

## K9.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

### AArch32

P1

```
STR R5, [R1]          ; message stored to shared memory location
DSB ST
STR R0, [R4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

### AArch64

P1

```
STR W5, [X1]          ; message stored to shared memory location
DSB ST
STR W0, [X4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR W5, [X1]
```

## K9.5 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- [Data cache maintenance instructions](#).
- [Instruction cache maintenance instructions](#) on page K9-6231.
- [TLB maintenance instructions and barriers](#) on page K9-6234.

### K9.5.1 Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- [Message passing to non-caching observers](#).
- [Multiprocessing message passing to non-caching observers](#) on page K9-6228.
- [Invalidating DMA buffers, non-functional example](#) on page K9-6229.
- [Invalidating DMA buffers, functional example with single PE](#) on page K9-6229.
- [Invalidating DMA buffers, functional example with multiple coherent PEs](#) on page K9-6230.

#### Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance instruction. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

##### AArch32

P1

```
STR R5, [R1]      ; updates data (assumed to be in P1 cache)
DCCMVAC R1        ; cleans cache to point of coherency
DMB              ; ensures effects of the clean will be observed before the
                  ; flag is set
STR R0, [R4]      ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([R4] == 1) ; waits for the flag (with order)
LDR R5, [R1]        ; reads the data
```

##### AArch64

P1

```
STR W5, [X1]      ; updates data (assumed to be in P1 cache)
DC CVAC, X1       ; cleans cache to point of coherency
DMB ISH          ; ensures effects of the clean will be observed before the
                  ; flag is set
STR W0, [X4]      ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([X4] == 1) ; waits for the flag (with order)
LDR W5, [X1]        ; reads the data
```

In this example, it is required that E1:R5==0x55.

## Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions combined with properties of barriers, means that the message passing principle for non-caching observers is:

### AArch32

P1

```
STR R5, [R1]      ; updates data (assumed to be in P1 cache)
STL R0, [R2]      ; sends a flag for P2 (ordered by the store release)
```

P2

```
WAIT ([R2] == 1)  ; waits for P1 flag
DMB               ; ensures cache clean is observed after P1 flag is observed
DCCMVA R1         ; cleans cache to point of coherency - will clean P1 cache
DMB               ; ensures effects of the clean will be observed before the
                  ; flag to E1 is set
STR R0, [R4]      ; sends flag to E1
```

E1

```
WAIT_ACQ ([R4] == 1) ; waits for P2 flag (ordered)
LDR R5, [R1]         ; reads data
```

### AArch64

P1

```
STR W5, [X1]      ; updates data (assumed to be in P1 cache)
STLR W0, [X2]     ; sends a flag for P2 (ordered)
```

P2

```
WAIT ([X2] == 1)  ; waits sfor P1 flag
DMB SY            ; ensure cache clean is observed after P1 flag is observed
DC CVAC, X1       ; cleans cache to point of coherency, will clean P1 cache
DMB SY            ; ensures effects of the clean will be observed before the
                  ; flag to E1 is set
STR W0, [X4]      ; sends flag to E1
```

E1

```
WAIT_ACQ ([X4] == 1) ; waits for P2 flag
LDR W5, [X1]         ; reads data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

### ————— Note —————

The cache maintenance instructions are not ordered by the Load-Acquire and Store-Release instructions.

## Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

### AArch32

P1

```
DCIMVAC R1      ; ensures cache is not dirty. A clean operation could be used
                ; but as the DMA will subsequently overwrite this region an
                ; invalidate operation is sufficient and usually more efficient
DMB             ; ensures cache invalidation is observed before the next store
                ; is observed
STR R0, [R3]    ; sends flag to external agent
WAIT_ACQ ([R4]==1) ; waits for a different flag from an external agent
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1) ; waits for flag
STR R5, [R1]     ; stores new data
STL R0, [R4]     ; sends a flag
```

### AArch64

P1

```
DC IVAC, X1     ; ensure cache is not dirty. A clean operation could be used
                ; but as the DMA will subsequently overwrite this region an
                ; invalidate operation is sufficient and usually more efficient
DMB SY         ; ensures cache invalidation is observed before the next store
                ; is observed
STR W0, [X3]    ; sends flag to external agent
WAIT_ACQ ([X4]==1) ; waits for a different flag from an external agent
LDR W5, [X1]
```

E1

```
WAIT ([X3] == 1) ; waits for flag
STR W5, [X1]     ; stores new data
STLR W0, [X4]    ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

## Invalidating DMA buffers, functional example with single PE

### AArch32

P1

```
DCIMVAC R1      ; ensures cache is not dirty. A clean operation could be used
                ; but as the DMA will subsequently overwrite this region an
                ; invalidate operation is sufficient and usually more efficient
DMB             ; ensures cache invalidation is observed before the next store
                ; is observed
STR R0, [R3]    ; sends flag to external agent
WAIT ([R4]==1) ; waits for a different flag from an external agent
DMB             ; ensures that cache invalidate is observed after the flag
                ; from external agent is observed
DCIMVAC R1      ; ensures cache discards stale copies before use
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1) ; waits for flag
```

```
STR R5, [R1]      ; stores new data
STL R0, [R4]      ; sends a flag
```

#### AArch64

P1

```
DC IVAC, X1      ; ensures cache is not dirty. A clean operation could be used
                  ; but as the DMA will subsequently overwrite this region an
                  ; invalidate operation is sufficient and usually more efficient
DMB SY           ; ensures cache invalidation is observed before the next store
                  ; is observed
STR W0, [X3]     ; sends flag to external agent
WAIT ([X4]==1)   ; waits for a different flag from an external agent
DMB SY           ; ensures that cache invalidate is observed after the flag
                  ; from external agent is observed
DC IVAC, X1      ; ensures cache discards stale copies before use
LDR W5, [X1]
```

E1

```
WAIT ([X3] == 1) ; waits for flag
STR W5, [X1]     ; stores new data
STLR W0, [X4]    ; sends a flag
```

In this example, the result  $P1:R5 == 0x55$  is required. Including a cache invalidation after the store by E1 to  $[R1]$  is observed ensures that the line is fetched from external memory after it has been updated.

### Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

#### AArch32

P0

```
(Use data from [R1], potentially using [R1] as scratch space)
STL R0, [R2]      ; signals release of [R1]
WAIT_ACQ ([R2] == 0) ; waits for new value from DMA
LDR R5, [R1]
```

P1

```
WAIT ([R2] == 1) ; waits for release of [R1] by P0
DCIMVAC R1       ; ensures caches are not dirty, an invalidate is sufficient
DMB
STR R0, [R3]     ; requests new data for [R1]
WAIT ([R4] == 1) ; waits for new data
DMB
DCIMVAC R1       ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]     ; signals availability of new [R1]
```

E1

```
WAIT ([R3] == 1) ; waits for new data request
STR R5, [R1]     ; sends new [R1]
DMB [ST]
STR R0, [R4]     ; indicates that new data is available to P1
```

#### AArch64

P0

```
(Use data from [X1], potentially using [X1] as scratch space)
STLR W0, [X2]    ; signals release of [X1]
```

```
WAIT_ACQ ([X2] == 0) ; waits for new value from DMA
LDR W5, [X1]
```

P1

```
WAIT ([X2] == 1) ; waits for release of [R1] by P0
DC IVAC, X1 ; ensures caches are not dirty, an invalidate is sufficient
DMB SY
STR W0, [X3] ; requests new data for [R1]
WAIT ([X4] == 1) ; waits for new data
DMB SY
DCIMVAC X1 ; ensures caches discard stale copies before use
DMB SY
STR WZR, [X2] ; signals availability of new [R1]
```

E1

```
WAIT ([X3] == 1) ; waits for new data request
STR W5, [X1] ; sends new [R1]
STR W0, [X4] ; indicates new data is available to P1
```

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

## K9.5.2 Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- [Ensuring the visibility of updates to instructions for a uniprocessor.](#)
- [Ensuring the visibility of updates to instructions for a multiprocessor on page K9-6232.](#)

### Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

#### AArch32

P1

```
STR R11, [R1] ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB
ICIMVAU R1 ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1
DSB ; ensures completion of the invalidation
ISB ; ensures instruction fetch path sees new instruction cache state
BX R1
```

In AArch64 state, the branch predictor maintenance is not required.

#### AArch64

P1

```
STR W11, [X1] ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1 ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH
IC IVAU, X1 ; ensures instruction cache/branch predictor discards stale data
```

```
DSB ISH          ; ensures completion of the invalidation
ISB              ; ensures instruction fetch path sees new instruction cache state
BR X1
```

#### **Note**

Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

### **Ensuring the visibility of updates to instructions for a multiprocessor**

The ARMv8 architecture requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

#### **AArch32**

P1

```
STR R11, [R1]    ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1       ; clean to PoU makes the new instruction visible to the instruction cache
DSB              ; ensures completion of the clean on all PEs
ICIMVAU R1       ; ensures instruction cache discards stale data
BPIMVA R         ; ensures branch predictor discards stale data
DSB              ; ensures completion of the instruction cache and branch predictor
                 ; invalidation on all PEs
STR R0, [R2]     ; sets flag to signal completion
ISB              ; synchronizes context on this PE
BX R1            ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1) ; waits for flag signalling completion
ISB              ; synchronizes context on this PE
BX R1            ; branches to new code
```

#### **AArch64**

P1

```
STR X11, [X1]    ; X11 contains a new instruction to be stored in program memory
DC CVAU, X1      ; clean to PoU makes the new instruction visible to the instruction cache
DSB ISH          ; ensures completion of the clean on all PEs
IC IVAU, X1      ; ensures instruction cache/branch predictor discards stale data
DSB ISH          ; ensures completion of the instruction cache/branch predictor
                 ; invalidation on all PEs
STR W0, [X2]     ; sets flag to signal completion
ISB              ; synchronizes context on this PE
BR R1            ; branches to new code
```

P2-Px

```
WAIT ([X2] == 1) ; waits for flag signalling completion
ISB              ; synchronizes context on this PE
BR X1            ; branches to new code
```

### Nonfunctional approach

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

#### AArch32

P1

```
STR R11, [R1]      ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1         ; clean to PoU makes the new instruction visible to the instruction cache
DSB               ; ensures completion of the clean on all PEs
ICIMVAU R1         ; ensures instruction cache discards stale data
BPIMVA R1          ; ensures branch predictor discards stale data
DMB               ; ensures ordering of the store after the invalidation
                  ; DOES NOT guarantee completion of instruction cache/branch
                  ; predictor on other PEs
STR R0, [R2]       ; sets flag to signal completion
DSB               ; ensures completion of the invalidation on all PEs
ISB               ; synchronizes context on this PE
BX R1              ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1)   ; waits for flag signalling completion
DSB                ; this DSB does not guarantee completion of P1
                  ; ICIMVAU/BPIMVA
ISB
BX R1
```

#### AArch64

P1

```
STR W11, [X1]      ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1        ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH           ; ensures completion of the clean on all PEs
IC IVAU, X1       ; ensures instruction cache/branch predictor discards stale data
DMB ISH           ; ensures ordering of the store after the invalidation
                  ; DOES NOT guarantee completion of instruction cache/branch
                  ; predictor on other PEs
STR W0, [X2]       ; sets flag to signal completion
DSB ISH           ; ensures completion of the invalidation on all PEs
ISB               ; synchronizes context on this PE
BR X1              ; branches to new code
```

P2-Px

```
WAIT ([X2] == 1)   ; waits for flag signalling completion
DSB ISH            ; this DSB does not guarantee completion of P1
                  ; ICIMVAU/BPIMVA
ISB
BR X1
```

In this example, P2...Px might not see the updated region of code at R1.

### K9.5.3 TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- [Ensuring the visibility of updates to translation tables for a uniprocessor.](#)
- [Ensuring the visibility of updates to translation tables for a multiprocessor on page K9-6235.](#)
- [Paging memory in and out on page K9-6235.](#)
- [Using break-before-make when updating translation table entries on page K9-6236.](#)

#### Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

The ARMv8 architecture requires that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

#### AArch32

P1

```
STR R11, [R1]      ; updates the translation table entry
DSB                ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                ; ensures completion of the BP and TLB invalidation
ISB                ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

#### AArch64

P1

```
STR X11, [X1]      ; updates the translation table entry
DSB ISH            ; ensures visibility of the update to translation table walks
TLBI VAE1, X10     ; assumes we are in the EL1
DSB ISH            ; ensures completion of the TLB invalidation
ISB                ; synchronise context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

## Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. The ARMv8 architecture requires a PE that executes a TLB maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

### AArch32

P1

```
STR R11, [R1]      ; updates the translation table entry
DSB                ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                ; ensures completion of the BP and TLB invalidation
ISB                ; Note ISB is not broadcast and must be executed locally
                  ; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed
```

### AArch64

P1

```
STR X11, [X1]      ; updates the translation table entry
DSB ISH            ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X10
DSB ISH            ; ensures completion of the TLB invalidation
ISB                ; Note ISB is not broadcast and must be executed locally
                  ; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

## Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

### AArch32

P1

```
STR R11, [R1]      ; updates the translation table for the region being paged out
DSB                ; ensures visibility of the update to translation table walks
TLBIMVAIS R10      ; invalidates the old entry
DSB                ; ensures completion of the invalidation on all PEs
```

```

ISB                ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                ; ensures completion of the memory transfer (this could be part of
                  ; LoadMemoryFromBackingStore)
ICIALLUIS          ; also invalidates the branch predictor
STR R9, [R1]       ; creates a new translation table entry with a new mapping
DSB                ; ensures completion of the instruction cache
                  ; and branch predictor invalidation
                  ; AND ensures visibility of the new translation table mapping
ISB                ; ensures synchronisation of this instruction stream

```

#### AArch64

P1

```

STR X11, [X1]      ; updates the translation table for the region being paged out
DSB ISH            ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X10   ; invalidates the old entry
DSB ISH            ; ensures completion of the invalidation on all PEs
ISB                ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ISH            ; ensures completion of the memory transfer (this could be part of
                  ; LoadMemoryFromBackingStore)
IC IALLUIS         ; also invalidates the branch predictor
STR X9, [X1]       ; creates a new translation table entry with a new mapping
DSB ISH            ; ensures completion of the instruction cache
                  ; and branch predictor invalidation
                  ; AND ensures visibility of the new translation table mapping
ISB                ; ensures synchronisation of this instruction stream

```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of `ICIALLUIS` in AArch32 state and `IC IALLUIS` in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` in AArch32 state and `IC IVAU` operations in AArch64 state. This invalidation must be done when the mapping used for the `ICIMVAU` and `IC IVAU` operations is valid but not executable.

### Using break-before-make when updating translation table entries

The ARM Architecture requires that reads to the same location are observed in order, and since application level software relies on this behavior, the operating system needs to maintain this illusion when it is changing a virtual to physical address mapping for a location, as is the case with copy on write or other memory management techniques. This illusion can be maintained provided that the software uses a break-before-make sequence when updating translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation entries involves any of:

- Changing the memory type.
- Changing the cacheability attributes
- Changing the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.

The architecture requires use of a break-before make sequence in these situations, see [Using break-before-make when updating translation table entries on page D4-2120](#) for more information. However, if software did not use a break-before-make approach, an implementation might give a result that would occur if the two reads to the same virtual address did not occur in program order. An example of such an occurrence would be an implementation of copy-on-write, where one PE is performing two reads to the same virtual address at the same time as a second PE,

running code associated with the operating system, is copying the data from one physical location that is mapped to by that virtual address, where the page was mapped as read-only, to a different physical location which will be mapped as read-write.

If the operating system changed the address mapping without going through an invalid entry, then it would be possible for a third PE to perform a write to the location that would be seen by the first load by the first PE, and not seen by the second load by the same PE.

The required break-before-make code sequence in this case is:

### AArch32

P1

```
; R1, R2 contain an invalid translation table entry (that is, one with bit[0] == 0)
; R3 contains the address of the translation table entry
; R4 contains the Virtual Address and ASID of the VA being remapped
; R5, R6 contain the new valid translation table entry
STRD R1, R2, [R3]      ; stores invalid entry
DSB ISH                ; ensures visibility of the update to translation table walks
TLBIMVAIS R4           ; invalidates the old entry
DSB ISH                ; ensures completion of the invalidation on all PEs
ICIAILLUIS             ; also invalidates the branch predictor
STRD R5, R6, [R3]      ; store new mapping
DSB ISH                ; ensures visibility of the update to translation table walks
ISB                    ; ensures synchronisation of this instruction stream
```

### ———— Note ————

This example shows an update to an entry in a translation table that is using the long-descriptor format.

### AArch64

P1

```
; X1 contains an invalid translation table entry (that is, one with bit[0] == 0)
; X2 contains the address of the translation table entry
; X3 contains the Virtual Address and ASID of the VA being remapped
; X4 contains the new valid translation table entry
STR X1, [X2]           ; stores invalid entry
DSB ISH                ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X3        ; invalidates the old entry
DSB ISH                ; ensures completion of the invalidation on all PEs
IC IALLUIS             ; also invalidates the branch predictor
STR X4, [X2]           ; store new mapping
DSB ISH                ; ensures visibility of the update to translation table walks
ISB                    ; ensures synchronisation of this instruction stream
```

If this sequence is correctly followed, then the architecture guarantees that the loads to a virtual address being remapped will be seen in the correct order.

The instruction cache maintenance is only required if the mapping from input address to output address has been changed as part of the change of the translation table entries, and the memory being moved is executable. In this example, the use of ICIAILLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state, and IC IVAU in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

## K9.5.4 Ordering of Memory-mapped device control with payloads

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

- When a processing element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.
- When a DMA peripheral has written to a buffer of data in memory, and the processing element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the processing element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped a to the DMA peripheral can be met by the insertion of a DSB <domain> instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. this is shown by the following code:

### AArch32

P1

```
STR R5, [R2]      ; data written to the data buffer
DSB
STR R0, [R4]      ; R4 contains the address of the DMA control register
```

### AArch64

P1

```
STR W5, [X2]      ; data written to the data buffer
DSB <domain>
STR W0, [X4]      ; X4 contains the address of the DMA control register
```

For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the processing element before the processing element reads the data buffer, the processing element must insert a DSB <domain> between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a slave, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

### AArch32

P1

```
WAIT ([R4] == 1)   ; R4 contains the address of the status register,
                   ; and the value '1' indicates completion of the DMA transfer
DSB
LDR R5, [R2]      ; reads data from the data buffer
```

### AArch64

P1

```
WAIT ([X4] == 1)   ; X4 contains the address of the status register,
                   ; and the value '1' indicates completion of the DMA transfer
DSB <domain>
LDR W5, [X2]      ; reads data from the data buffer
```

## K9.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

The following sections describe the ARMv7 compatible approaches for ordering, using DMB and DSB barriers:

- [Simple ordering and barrier cases.](#)
- [Load-Exclusive, Store-Exclusive and barriers on page K9-6243.](#)
- [Using a mailbox to send an interrupt on page K9-6245.](#)
- [Cache and TLB maintenance instructions and barriers on page K9-6245.](#)

### K9.6.1 Simple ordering and barrier cases

ARM implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

#### Simple weakly consistent ordering example

P1

```
STR R5, [R1]
LDR R6, [R2]
```

P2

```
STR R6, [R2]
LDR R5, [R1]
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

#### Message passing

The following sections describe:

- [Weakly-ordered message passing problem.](#)
- [Message passing with multiple observers on page K9-6241.](#)

#### Weakly-ordered message passing problem

P1

```
STR R5, [R1]          ; sets new data
STR R0, [R2]          ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)         ; waits on flag
LDR R5, [R1]          ; reads new data
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

#### Resolving by the addition of barriers

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2:R5==0x55 is guaranteed, as follows:

P1

```
STR R5, [R1]          ; sets new data
DMB [ST]              ; ensures all observers observe data before the flag
STR R0, [R2]          ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)          ; waits on flag
DMB                    ; ensures that the load of data is after the flag has been observed
LDR R5, [R1]
```

### Resolving by the use of barriers and address dependency

There is a rule within the ARM architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order.  
Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an *address dependency*. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.  
This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a *control dependency*.  
Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table K9-1 shows examples of address dependencies, control dependencies, and an address and control dependency.

Table K9-1 Dependency examples

Address dependency		Control dependency		Address and control dependency <sup>a</sup>
(a)	(b)	(c)	(d)	(e)
LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]
LDR r2, [r1]	AND r1, r1, #0	CMP r1, #55	CMP r1, #55	CMP r1, #0
	LDR r2, [r3, r1]	LDRNE r2, [r3]	MOVNE r4, #22	LDRNE r2, [r1]
			LDR r2, [r3, r4]	

a. The address dependency takes priority.

This means that the data transfer example of *Weakly-ordered message passing problem* on page K9-6239 can also be satisfied as shown in the following example:

P1

```
STR R5, [R1]           ; sets new data
DMB [ST]               ; ensures all observers observe data before the flag
STR R0, [R2]           ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load has an address dependency on R12
                        ; and so is ordered after the flag has been seen
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a DMB to ensure that P2 does not observe the write of [R2] before the write of [R1].

### Message passing with multiple observers

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:

```
P1
    STR R5, [R1]           ; sets new data
    STR R0, [R2]           ; sends flag indicating data ready

P2
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]      ; the load has an address dependency on R12
                           ; and so is ordered after the flag has been seen

P3
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]      ; the load is address dependent on R12
                           ; and so is ordered after the flag has been seen
```

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

### Resolving by the addition of barriers

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value 0x55:

```
P1
    STR R5, [R1]           ; sets new data
    DMB [ST]               ; ensures all observers observe data before the flag
    STR R0, [R2]           ; sends flag indicating data ready

P2
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is the destination of LDR in WAIT macro
    LDR R5, [R1, R12]      ; the load has an address dependency on R12
                           ; and so is ordered after the flag has been seen

P3
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is the destination of LDR in WAIT macro
    LDR R5, [R1, R12]      ; the load has an address dependency on R12
                           ; and so is ordered after the flag has been seen
```

### Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

```
P1
    STR R5, [R1, #offset]  ; sets new data in a field
    DMB [ST]               ; ensures all observers observe data before base address is updated
    STR R1, [R2]           ; updates base address

P2
    LDR R1, [R2]           ; reads for base address
    CMP R1, #0             ; checks if it is valid
    BEQ null_trap
```

```
LDR R5, [R1, #offset] ; uses base address to read field
```

If the null trap is not taken, it is required that  $P2:R5 == 0x55$ . This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.

P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

### Posting a store before polling for acknowledgement

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

P1

```
STR R0, [R2]
WAIT ([R3]==1)
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
```

In ARMv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For ARMv7 implementations with the Multiprocessing Extensions and for ARMv8, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a DMB instruction prevents this deadlock in ARMv7 implementations that do not include the Multiprocessing Extensions:

P1

```
STR R0, [R2]
DMB
WAIT ([R3]==1)
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
```

The DMB executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

P1

```
STR R0, [R2]
WAIT ([R2]==2)
```

P2

```
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

In this example, the same deadlock can occur in ARMv7 implementations that do not include the Multiprocessing Extensions, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a DMB instruction prevents this deadlock:

P1

```
STR R0, [R2]
DMB
WAIT ([R2]==2)
```

P2

```
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

### WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A DSB barrier instruction is required if it is necessary to ensure that memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in [Posting a store before polling for acknowledgement on page K9-6242](#), or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

P1

```
STR R0, [R2]
DSB
Loop
WFI
B Loop
```

However, if the example in [Posting a store before polling for acknowledgement on page K9-6242](#) is extended to include a WFE, there is no risk of a deadlock. The extended example is:

P1

```
STR R0, [R2]
DMB
Loop
LDR R12, [R3]
CMP R12, #1
WFENE
BNE Loop
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
DSB
SEV
```

In this example:

- The DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1.
- The dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see [Use of Wait For Event \(WFE\) and Send Event \(SEV\) with locks on page K9-6244](#).

## K9.6.2 Load-Exclusive, Store-Exclusive and barriers

The Load-Exclusive and Store-Exclusive instructions, described in [Synchronization and semaphores on page B2-121](#), are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

## Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

Px

```
Loop
LDREX R5, [R1]          ; reads lock
CMP R5, #0              ; checks if 0
STREXEQ R5, R0, [R1]    ; attempts to store new value
CMPEQ R5, #0            ; tests if store succeeded
BNE Loop                ; retries if not
DMB                     ; ensures that all subsequent accesses are observed after the
                        ; gaining of the lock is observed
                        ; loads and stores in the critical region can now be performed
```

## Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a DMB usually precedes the lock release, as the following example shows.

Px

```
                        ; loads and stores in the critical region
MOV R0, #0
DMB                     ; ensures all previous accesses are observed before the lock is cleared
STR R0, [R1]           ; clears the lock
```

## Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture includes Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or *spinlock*, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the SEV instruction, is seen by the suspended observer. An observer that holds the lock executes an SEV instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the SEV instruction is executed and the event is sent. This requires the use of DSB instruction, rather than DMB.

Therefore, the following is an example of lock acquire code using WFE:

Px

```
Loop
LDREX R5, [R1]          ; reads lock
CMP R5, #0              ; checks if 0
WFE                     ; sleeps if the lock is held
STREXEQ R5, R0, [R1]    ; attempts to store new value
CMPEQ R5, #0            ; tests if store succeeded
BNE Loop                ; retries if not
DMB                     ; ensures that all subsequent accesses are observed after the
                        ; gaining of the lock is observed
                        ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code using SEV:

Px

```
; loads and stores in the critical region
MOV R0, #0
DMB                ; ensures all previous accesses are observed before the lock is cleared
STR R0, [R1]       ; clears the lock
DSB                ; ensures completion of the store that cleared the lock before
                  ; sending the event
SEV
```

### K9.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

P1

```
STR R5, [R1]       ; message stored to shared memory location
DSB [ST]
STR R1, [R4]       ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

#### ————— **Note** —————

The DSB executed by P1 ensures global observation of the store to [R1]. The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

### K9.6.4 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- [Data cache maintenance instructions](#).
- [Instruction cache maintenance instructions](#) on page K9-6248.
- [TLB maintenance instructions and barriers](#) on page K9-6249.

#### Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- [Message passing to non-caching observers](#).
- [Multiprocessing message passing to non-caching observers](#) on page K9-6246.
- [Invalidating DMA buffers, non-functional example](#) on page K9-6246.
- [Invalidating DMA buffers, functional example with single PE](#) on page K9-6247.
- [Invalidating DMA buffers, functional example with multiple coherent PEs](#) on page K9-6247.

#### Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

P1

```

STR R5, [R1]          ; updates data (assumed to be in P1's cache)
DCCMVAC R1            ; cleans cache to point of coherency
DMB                  ; ensures effects of the clean will be observed before the flag is set
STR R0, [R4]          ; sends flag to external agent (Non-cacheable location)

```

E1

```

WAIT ([R4] == 1)      ; waits for the flag
DMB                  ; ensures that flag has been seen before reading data
LDR R5, [R1]          ; reads the data

```

In this example, it is required that E1:R5==0x55.

### **Multiprocessing message passing to non-caching observers**

The broadcast nature of the cache maintenance instructions in ARMv8, and in ARMv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

P1

```

STR R5, [R1]          ; updates data (assumed to be in P1's cache)
DMB [ST]              ; ensures new data is observed before the flag to P2 is set
STR R0, [R2]          ; sends flag to P2

```

P2

```

WAIT ([R2] == 1)      ; waits for flag from P1
DMB                  ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1           ; cleans cache to point of coherency - this cleans the cache of P1
DMB                  ; ensures effects of the clean are observed before the flag to E1 is set
STR R0, [R4]          ; sends flag to E1

```

E1

```

WAIT ([R4] == 1)      ; waits for flag from P2
DMB                  ; ensures that flag has been observed before reading the data
LDR R5, [R1]          ; reads the data

```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

### **Invalidating DMA buffers, non-functional example**

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

P1

```

DCIMVAC R1            ; ensures caches are not dirty. A clean operation could be
                      ; used but the DMA overwrites this region so an invalidate operation
                      ; is sufficient and usually more efficient
DMB                  ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3]          ; sends flag to external agent
WAIT ([R4]==1)        ; waits for a different flag from an external agent
DMB                  ; observes flag from external agent before reading new data. However [R1]
                      ; could have been brought into cache earlier
LDR R5, [R1]

```

E1

```

WAIT ([R3] == 1)      ; waits for flag
STR R5, [R1]          ; stores new data
DMB
STR R0, [R4]          ; sends a flag

```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

### **Invalidating DMA buffers, functional example with single PE**

P1

```
DCIMVAC R1          ; ensures cache is not dirty. A clean operation could be
                    ; used but the DMA overwrites this region so an invalidate operation
                    ; is sufficient and usually more efficient
DMB                 ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3]        ; sends flag to external agent
WAIT ([R4]==1)      ; waits for a different flag from an external agent
DMB                 ; ensures that cache invalidate is observed after the flag
                    ; from external agent is observed
DCIMVAC R1          ; ensures cache discards stale copies before use
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1)    ; waits for flag
STR R5, [R1]        ; stores new data
DMB [ST]
STR R0, [R4]        ; sends a flag
```

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

### **Invalidating DMA buffers, functional example with multiple coherent PEs**

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

P0

```
(Use data from [R1], potentially using [R1] as scratch space)
DMB
STR R0, [R2]        ; signals release of [R1]
WAIT ([R2] == 0)    ; waits for new value from DMA
DMB
LDR R5, [R1]
```

P1

```
WAIT ([R2] == 1)    ; waits for release of [R1] by P0
DCIMVAC R1          ; ensures caches are not dirty, invalidate is sufficient
DMB
STR R0, [R3]        ; requests new data for [R1]
WAIT ([R4] == 1)    ; waits for new data
DMB
DCIMVAC R1          ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]        ; signals availability of new [R1]
```

E1

```
WAIT ([R3] == 1)    ; waits for new data request
STR R5, [R1]        ; sends new [R1]
DMB [ST]
STR R0, [R4]        ; indicates new data available to P1
```

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

## Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- [Ensuring the visibility of updates to instructions for a uniprocessor.](#)
- [Ensuring the visibility of updates to instructions for a multiprocessor.](#)

### Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

P1

```
STR R11, [R1]          ; R11 contains a new instruction to store in program memory
DCCMVAU R1             ; clean to PoU makes new instructions visible to instruction cache
DSB                   ; ensures instruction cache and branch predictor discard stale data
ICIMVAU R1             ; ensures instruction cache and branch predictor discard stale data
BPIMVA R1              ; ensures instruction cache and branch predictor discard stale data
DSB                   ; ensures completion of the invalidation
ISB                   ; ensures instruction fetch path observes new instruction cache state
BX R1
```

### Ensuring the visibility of updates to instructions for a multiprocessor

ARMv8, and an ARMv7 implementation that includes the Multiprocessing Extensions, requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

P1

```
STR R11, [R1]          ; R11 contains a new instruction to store in program memory
DCCMVAU R1             ; clean to PoU makes new instructions visible to instruction cache
DSB                   ; ensures completion of the clean on all processors
ICIMVAU R1             ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1              ; ensures instruction cache/branch predictor discards stale data
DSB                   ; ensures completion of the instruction cache and branch predictor
                       ; invalidation on all PEs
STR R0, [R2]           ; sets flag to signal completion
ISB                   ; synchronizes context on this PE
BX R1                  ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1)       ; waits for flag signaling completion
ISB                   ; synchronizes context on this processor
BX R1                  ; branches to new code
```

### Nonfunctional approach

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

P1

```
STR R11, [R1]          ; R11 contains a new instruction to store in program memory
DCCMVAU R1             ; clean to PoU makes new instructions visible to instruction cache
```

```

DSB                                ; ensure completion of the clean on all PEs
ICIMVAU R1                        ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DMB                                ; ensure ordering of the store after the invalidation
                                ; DOES NOT guarantee completion of instruction cache/branch
                                ; predictor on other PEs
STR R0, [R2]                      ; sets flag to signal completion
DSB                                ; ensures completion of the invalidation on all PEs
ISB                                ; synchronizes context on this PE
BX R1                             ; branches to new code

```

P2-Px

```

WAIT ([R2] == 1)                 ; waits for flag signaling completion
DSB                                ; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
ISB
BX R1

```

In this example, P2...Px might not see the updated region of code at R1.

## TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- [Ensuring the visibility of updates to translation tables for a uniprocessor.](#)
- [Ensuring the visibility of updates to translation tables for a multiprocessor on page K9-6250.](#)
- [Paging memory in and out on page K9-6250.](#)

### Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

P1

```

STR R11, [R1]                    ; updates the translation table entry
DSB                                ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                                ; ensures completion of the BP and TLB invalidation
ISB                                ; synchronizes context on this PE
;
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using the old mapping have been completed

```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

### **Ensuring the visibility of updates to translation tables for a multiprocessor**

The same code sequence can be used in a multiprocessing system. In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, a PE that executes a TLB maintenance instruction must execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

P1

```
STR R11, [R1]          ; updates the translation table entry
DSB                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                    ; ensures completion of the BP and TLB invalidation
ISB                    ; Note ISB is not broadcast and must be executed locally on other PEs
;
; new translation table entry can be relied upon at this point and all accesses generated by any
; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

### **Paging memory in and out**

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

P1

```
STR R11, [R1]          ; updates the translation table for the region being paged out
DSB                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R10          ; invalidates the old entry
DSB                    ; ensures completion of the invalidation on all processors
ISB                    ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                    ; ensures completion of the memory transfer (this could be part of
; LoadMemoryFromBackingStore
ICIALUIS               ; also invalidates the branch predictor
STR R9, [R1]           ; creates a new translation table entry with a new mapping
DSB                    ; ensures completion of instruction cache and branch predictor invalidation
; and ensures visibility of the new translation table mapping
ISB                    ; ensures synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of SaveMemoryPageToBackingStore and LoadMemoryFromBackingStore. LoadMemoryFromBackingStore is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of `ICIALUIS` to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` operations. This invalidation must be done when the mapping used for the `ICIMVAU` operations is valid but not executable.

# Appendix K10

## ARM Pseudocode Definition

This appendix provides a definition of the pseudocode that is used in this manual, and defines some *helper* procedures and functions that are used by pseudocode. It contains the following sections:

- [About the ARM pseudocode on page K10-6254.](#)
- [Pseudocode for instruction descriptions on page K10-6255.](#)
- [Data types on page K10-6257.](#)
- [Operators on page K10-6262.](#)
- [Statements and control structures on page K10-6268.](#)
- [Built-in functions on page K10-6273.](#)
- [Miscellaneous helper procedures and functions on page K10-6276.](#)
- [ARM pseudocode definition index on page K10-6278.](#)

---

### **Note**

---

This appendix is not a formal language definition for the pseudocode. It is a guide to help understand the use of ARM pseudocode. This appendix is not complete. Changes are planned for future releases.

---

## K10.1 About the ARM pseudocode

The ARM pseudocode provides precise descriptions of some areas of the ARM architecture. This includes description of the decoding and operation of all valid instructions. [Pseudocode for instruction descriptions on page K11-6021](#) gives general information about this instruction pseudocode, including its limitations.

The following sections describe the ARM pseudocode in detail:

- [Data types on page K10-6257](#).
- [Operators on page K10-6262](#).
- [Statements and control structures on page K10-6268](#).

[Built-in functions on page K10-6273](#) and [Miscellaneous helper procedures and functions on page K10-6276](#) describe some built-in functions and pseudocode helper functions that are used by the pseudocode functions that are described elsewhere in this manual. [ARM pseudocode definition index on page K10-6278](#) contains the indexes to the pseudocode.

### K10.1.1 General limitations of ARM pseudocode

The pseudocode statements IMPLEMENTATION\_DEFINED, SEE, UNDEFINED, and UNPREDICTABLE indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

- Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
- No subsequent behavior indicated by the pseudocode occurs.

For more information, see [Special statements on page K10-6272](#).

## K10.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in [General limitations of ARM pseudocode on page K10-6254](#) and [Limitations of the instruction pseudocode on page K10-6256](#).

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. [Instruction encoding diagrams and instruction pseudocode](#) gives more information about the pseudocode provided for each instruction.

### K10.2.1 Instruction encoding diagrams and instruction pseudocode

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.
- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the `EncodingSpecificOperations()` function, either at its start or only after a condition code check performed by `if ConditionPassed()` then.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.
- A *should be* 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is CONSTRAINED UNPREDICTABLE. For more information, see [SBZ or SBO fields T32 and A32 in instructions on page K1-6100](#).
- A named single bit or a bit in a named multi-bit field. The cond field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.
- The encoding diagram is for an A32/T32 instruction that does not have a cond field in bits[31:28].
- The encoding diagram is for an A32/T32 instruction that has a cond field in bits[31:28], and bits[31:28] of the instruction are not 0b1111.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and UNDEFINED, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.
2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.
3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.

In a few cases, the encoding diagram contains more than one bit or field with same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the `Consistent()` function to specify what happens if they are not identical. `Consistent()` returns `TRUE` if all instruction bits or fields with the same name as its argument have the same value, and `FALSE` otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.

There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is `CONSTRAINED UNPREDICTABLE`. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the *should be* bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as `CONSTRAINED UNPREDICTABLE`, see [SBZ or SBO fields T32 and A32 in instructions on page K1-6100](#).
5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The `ConditionPassed()` call in the common pseudocode, if present, performs step 2, and the `EncodingSpecificOperations()` call performs steps 3 and 4.

## K10.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses see [Ordering constraints on page E2-2766](#).
- Pseudocode does not describe the exact rules when an `UNDEFINED` instruction fails its condition code check. In such cases, the `UNDEFINED` pseudocode statement lies inside the `if ConditionPassed() then ...` structure, either directly or in the `EncodingSpecificOperations()` function call, and so the pseudocode indicates that the instruction executes as a NOP. [Conditional execution of undefined instructions on page G1-4378](#) describes the exact rules.
- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. [Combinations of floating-point exceptions on page E1-2745](#) describes the exact rules.

### **Note**

There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as `Abort()`, or implicitly, for example if an interrupt is taken during execution of an LDM instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in [Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340](#).

## K10.3 Data types

This section describes:

- [General data type rules](#).
- [Bitstrings](#).
- [Integers](#) on page K10-6258.
- [Reals](#) on page K10-6258.
- [Booleans](#) on page K10-6258.
- [Enumerations](#) on page K10-6259.
- [Structures](#) on page K10-6259.
- [Tuples](#) on page K10-6260.
- [Arrays](#) on page K10-6261.

### K10.3.1 General data type rules

ARM architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- Tuple.
- Struct.
- Array.

The type of a literal is determined by its syntax. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables `x`, `y` and `z` to have types integer, bitstring of length 1, and Boolean, respectively.

```
x = 1;
y = '1';
z = TRUE;
```

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named `count` is an integer.

```
integer count;
```

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

### K10.3.2 Bitstrings

This section describes the bitstring data type.

#### Syntax

`bits(N)`      The type name of a bitstring of length `N`.  
`bit`            A synonym of `bits(1)`.

#### Description

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 0.

Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type bit are '0' and '1'. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right  $N-1$  to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit  $N-1$  is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard *little-endian* order. That is, the leftmost bit of a bitstring of length  $N$  is bit  $(N-1)$  and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

### K10.3.3 Integers

This section describes the data type for integer numbers.

#### Syntax

integer      The type name for the integer data type.

#### Description

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as 0, 15, -1234. They can also be written in C-style hexadecimal form, such as 0x55 or 0x80000000. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, 0x80000000 is the integer  $+2^{31}$ . If  $-2^{31}$  needs to be written in hexadecimal, it must be written as -0x80000000.

### K10.3.4 Reals

This section describes the data type for real numbers.

#### Syntax

real      The type name for the real data type.

#### Description

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as reals.

Real constant literals are written in decimal form with a decimal point. This means 0 is an integer constant literal, but 0.0 is a real constant literal.

### K10.3.5 Booleans

This section describes the Boolean data type.

## Syntax

`boolean`      The type name for the Boolean data type.

`TRUE`          The two values a Boolean variable can take.

## Description

A Boolean is a logical TRUE or FALSE value.

### ————— Note —————

This is not the same type as `bit`, which is a bitstring of length 1. A Boolean can only take on one of two values: TRUE or FALSE.

## K10.3.6 Enumerations

This section describes the enumeration data type.

### Syntax and examples

`enumeration`      Keyword to defined a new enumeration type.

`enumeration Example {Example_One, Example_Two, Example_Three};`  
                          A definition of a new enumeration called `Example`, which can take on the values `Example_One`, `Example_Two`, `Example_Three`.

## Description

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations.

Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its *type name*, or *type*, and the named values are its possible *values*.

## K10.3.7 Structures

This section describes the structure data type.

### Syntax and examples

`type`              The keyword used to declare the structure data type.

`type ShiftSpec is (bits(2) shift, integer amount)`  
                          An example definition for a new structure called `ShiftSpec` that contains an bitstring member called `shift` and a integer member named `amount`. Structure definitions must not be terminated with a semicolon.

`ShiftSpec abc;`  
                          A declaration of a variable named `abc` of type `ShiftSpec`.

`abc.shift`  
                          Syntax to refer to the individual members within the structure variable.

## Description

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.

In the syntax section, the example defines a structure called `ShiftSpec` with two members. The first is a bitstring of length 2 named `shift` and the second is an integer named `amount`. After declaring a variable of that type named `abc`, the members of this structure are referred to as `abc.shift` and `abc.amount`.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

```
type ShiftSpec1 is (bits(2) shift, integer amount)
type ShiftSpec2 is (bits(2) shift, integer amount)
```

`ShiftSpec1` and `ShiftSpec2` are two different types despite having identical definitions. This means that the value in a variable of type `ShiftSpec1` cannot be assigned to variable of type `ShiftSpec2`.

### K10.3.8 Tuples

This section describes the tuple data type.

## Examples

```
(bits(32) shifter_result, bit shifter_carry_out)
```

An example of the tuple syntax.

```
(shift_t, shift_n) = ('00', 0);
```

An example of assigning values to a tuple.

## Description

A tuple is an ordered set of data items, separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function `Shift_C()`, which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type `bits(32)` and the second of type `bit`.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type `(bits(32), bit)`. The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be a tuple of type `(bits(2), integer)`.

## K10.3.9 Arrays

This section describes the array data type.

### Syntax

array            The type name for the array data type.

```
array data_type array_name[A..B];
```

Declaration of an array of type `data_type`, which might be compound data type. It is named `array_name` and is indexed with an integer range from `A` to `B`.

### Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then `..`, then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0 to 30.

```
array bits(64) _R[0..30];
```

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

- Enumerations always contain at least one symbolic constant named value.
- Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as `R[i]`, `MemU[address, size]` or `Elem[vector, i, size]`. These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See [Function and procedure calls on page K10-6268](#).

## K10.4 Operators

This section describes:

- [Relational operators](#).
- [Boolean operators](#).
- [Bitstring operators](#) on page K10-6263.
- [Arithmetic operators](#) on page K10-6263.
- [The assignment operator](#) on page K10-6264.
- [Precedence rules](#) on page K10-6266.
- [Conditional expressions](#) on page K10-6266.
- [Operator polymorphism](#) on page K10-6266.

### K10.4.1 Relational operators

The following operations yield results of type `boolean`.

#### Equality and non-equality

If two variables `x` and `y` are of the same type, their values can be tested for equality by using the expression `x == y` and for non-equality by using the expression `x != y`. In both cases, the result is of type `boolean`.

Both `x` and `y` must be of type `bits(N)`, `real`, `enumeration`, `boolean`, or `integer`. Named values from an enumeration can only be compared if they are both from the same enumeration. An exception is that a bitstring can be tested for equality with an integer to allow a `d==15` test.

A special form of comparison is defined with a bitstring literal that can contain bit values `'0'`, `'1'`, and `'x'`. Any bit with value `'x'` is ignored in determining the result of the comparison. For example, if `opcode` is a 4-bit bitstring, the expression `opcode == '1x0x'` matches the values `'1000'`, `'1100'`, `'1001'`, and `'1101'`. This is known as a bitmask.

#### ————— Note —————

This special form is permitted in the implied equality comparisons in the `when` parts of `case ... of ...` structures.

#### Comparisons

If `x` and `y` are integers or reals, then `x < y`, `x <= y`, `x > y`, and `x >= y` are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results.

#### Set membership with IN

`<expression> IN {<set>}` produces `TRUE` if `<expression>` is a member of `<set>`. Otherwise, it is `FALSE`. `<set>` must be a list of expressions separated by commas.

### K10.4.2 Boolean operators

If `x` is a Boolean expression, then `!x` is its logical inverse.

If `x` and `y` are Boolean expressions, then `x && y` is the result of ANDing them together. As in the C language, if `x` is `FALSE`, the result is determined to be `FALSE` without evaluating `y`.

#### ————— Note —————

This is known as short circuit evaluation.

If `x` and `y` are booleans, then `x || y` is the result of ORing them together. As in the C language, if `x` is `TRUE`, the result is determined to be `TRUE` without evaluating `y`.

### Note

If  $x$  and  $y$  are booleans or Boolean expressions, then the result of  $x \neq y$  is the same as the result of exclusive-ORing  $x$  and  $y$  together. The operator EOR only accepts bitstring arguments.

## K10.4.3 Bitstring operators

The following operations can be applied only to bitstrings.

### Logical operations on bitstrings

If  $x$  is a bitstring, NOT( $x$ ) is the bitstring of the same length obtained by logically inverting every bit of  $x$ .

If  $x$  and  $y$  are bitstrings of the same length,  $x$  AND  $y$ ,  $x$  OR  $y$ , and  $x$  EOR  $y$  are the bitstrings of that same length obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of  $x$  and  $y$  together.

### Bitstring concatenation and slicing

If  $x$  and  $y$  are bitstrings of lengths  $N$  and  $M$  respectively, then  $x:y$  is the bitstring of length  $N+M$  constructed by concatenating  $x$  and  $y$  in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is  $x\langle\text{integer\_list}\rangle$ , where  $x$  is the integer or bitstring being sliced, and  $\langle\text{integer\_list}\rangle$  is a comma-separated list of integers enclosed in angle brackets. The length of the resulting bitstring is equal to the number of integers in  $\langle\text{integer\_list}\rangle$ . In  $x\langle\text{integer\_list}\rangle$ , each of the integers in  $\langle\text{integer\_list}\rangle$  must be:

- $\geq 0$ .
- $< \text{Len}(x)$  if  $x$  is a bitstring.

The definition of  $x\langle\text{integer\_list}\rangle$  depends on whether  $\text{integer\_list}$  contains more than one integer:

- If  $\text{integer\_list}$  contains more than one integer,  $x\langle i, j, k, \dots, n \rangle$  is defined to be the concatenation:  
 $x\langle i \rangle : x\langle j \rangle : x\langle k \rangle : \dots : x\langle n \rangle$ .
- If  $\text{integer\_list}$  consists of just one integer  $i$ ,  $x\langle i \rangle$  is defined to be:
  - If  $x$  is a bitstring, '0' if bit  $i$  of  $x$  is a zero and '1' if bit  $i$  of  $x$  is a one.
  - If  $x$  is an integer, and  $y$  is the unique integer in the range  $0$  to  $2^{i+1}-1$  that is congruent to  $x$  modulo  $2^{i+1}$ . Then  $x\langle i \rangle$  is '0' if  $y < 2^i$  and '1' if  $y \geq 2^i$ .  
Loosely, this definition treats an integer as equivalent to a sufficiently long two's complement representation of it as a bitstring.

The notation for a range expression is  $i:j$  with  $i \geq j$  is shorthand for the integers in order from  $i$  down to  $j$ , with both end values included. For example,  $\text{instr}\langle 31:28 \rangle$  represents  $\text{instr}\langle 31, 30, 29, 28 \rangle$ .

$x\langle\text{integer\_list}\rangle$  is assignable provided  $x$  is an assignable bitstring and no integer appears more than once in  $\langle\text{integer\_list}\rangle$ . In particular,  $x\langle i \rangle$  is assignable if  $x$  is an assignable bitstring and  $0 \leq i < \text{Len}(x)$ .

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit $\langle 31 \rangle$  as N. In such cases, the syntax APSR.N is used as a more readable synonym for APSR $\langle 31 \rangle$  as named bits can be referred to with the same syntax as referring to members of a struct. A comma-separated list of named bits enclosed in angle brackets following the register name allows multiple bits to be addressed simultaneously. For example, APSR. $\langle N, C, Q \rangle$  is synonymous with APSR  $\langle 31, 29, 27 \rangle$ .

## K10.4.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.

## Unary plus and minus

If  $x$  is an integer or real, then  $+x$  is  $x$  unchanged,  $-x$  is  $x$  with its sign reversed. Both are of the same type as  $x$ .

## Addition and subtraction

If  $x$  and  $y$  are integers or reals,  $x+y$  and  $x-y$  are their sum and difference. Both are of type integer if  $x$  and  $y$  are both of type integer, and real otherwise.

There are two cases where the types of  $x$  and  $y$  can be different. A bitstring and an integer can be added together to allow the operation  $PC + 4$ . An integer can be subtracted from a bitstring to allow the operation  $PC - 2$ .

If  $x$  and  $y$  are bitstrings of the same length  $N$ , so that  $N = \text{Len}(x) = \text{Len}(y)$ , then  $x+y$  and  $x-y$  are the least significant  $N$  bits of the results of converting  $x$  and  $y$  to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

$$\begin{aligned} x+y &= (\text{SInt}(x) + \text{SInt}(y))\langle N-1:0 \rangle \\ &= (\text{UInt}(x) + \text{UInt}(y))\langle N-1:0 \rangle \\ x-y &= (\text{SInt}(x) - \text{SInt}(y))\langle N-1:0 \rangle \\ &= (\text{UInt}(x) - \text{UInt}(y))\langle N-1:0 \rangle \end{aligned}$$

If  $x$  is a bitstring of length  $N$  and  $y$  is an integer,  $x+y$  and  $x-y$  are the bitstrings of length  $N$  defined by  $x+y = x + y\langle N-1:0 \rangle$  and  $x-y = x - y\langle N-1:0 \rangle$ . Similarly, if  $x$  is an integer and  $y$  is a bitstring of length  $M$ ,  $x+y$  and  $x-y$  are the bitstrings of length  $M$  defined by  $x+y = x\langle M-1:0 \rangle + y$  and  $x-y = x\langle M-1:0 \rangle - y$ .

## Multiplication

If  $x$  and  $y$  are integers or reals, then  $x * y$  is the product of  $x$  and  $y$ . It is of type integer if  $x$  and  $y$  are both of type integer, and real otherwise.

## Division and modulo

If  $x$  and  $y$  are reals, then  $x/y$  is the result of dividing  $x$  by  $y$ , and is always of type real.

If  $x$  and  $y$  are integers, then  $x \text{ DIV } y$  and  $x \text{ MOD } y$  are defined by:

$$\begin{aligned} x \text{ DIV } y &= \text{RoundDown}(x/y) \\ x \text{ MOD } y &= x - y * (x \text{ DIV } y) \end{aligned}$$

It is a pseudocode error to use any of  $x/y$ ,  $x \text{ MOD } y$ , or  $x \text{ DIV } y$  in any context where  $y$  can be zero.

## Scaling

If  $x$  and  $n$  are of type integer, then:

- $x \ll n = \text{RoundDown}(x * 2^n)$ .
- $x \gg n = \text{RoundDown}(x * 2^{-(n)})$ .

## Raising to a power

If  $x$  is an integer or a real and  $n$  is an integer then  $x^n$  is the result of raising  $x$  to the power of  $n$ , and:

- If  $x$  is of type integer then  $x^n$  is of type integer.
- If  $x$  is of type real then  $x^n$  is of type real.

### K10.4.5 The assignment operator

The assignment operator is the  $=$  character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

`<assignable_expression> = <expression>;`

This following subsection defines valid expression syntax.

## General expression syntax

An expression is one of the following:

- A literal.
- A variable, optionally preceded by a data type name to declare its type.
- The word UNKNOWN preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register defined in an ARM architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as '0' and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

### ———— Note ————

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

- Variables.
- The results of applying some operators to other expressions.  
The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

### ———— Note ————

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as `-` to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```
(x, y) = (function_1(), function_2());
```

Every expression has a data type.

- For a literal, this data type is determined by the syntax of the literal.
- For a variable, there are the following possible sources for the data type
  - An optional preceding data type name.
  - A data type the variable was given earlier in the pseudocode by recursive application of this rule.

- A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

#### K10.4.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables and function invocations are evaluated with higher priority than any operators using their results, but see [Boolean operators on page K10-6262](#).
2. Operators on integers follow the normal operator precedence rules of *exponentiation before multiply/divide before add/subtract*, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if *i*, *j* and *k* are integer variables, *i* > 0 && *j* > 0 && *k* > 0 is acceptable, but *i* > 0 && *j* > 0 || *k* > 0 is not.

#### K10.4.7 Conditional expressions

If *x* and *y* are two values of the same type and *t* is a value of type `boolean`, then `if t then x else y` is an expression of the same type as *x* and *y* that produces *x* if *t* is `TRUE` and *y* if *t* is `FALSE`.

#### K10.4.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator `+` has forms that act on various combinations of integers, reals and bitstrings.

[Table K10-1](#) summarizes the operand types valid for each unary operator and the result type. [Table K10-2](#) summarizes the operand types valid for each binary operator and the result type.

**Table K10-1 Result and operand types permitted for unary operators**

Operator	Operand Type	Result Type
-	integer	integer
	real	real
NOT	bits(N)	bits(N)
!	boolean	boolean

**Table K10-2 Result and operand types permitted for binary operators**

Operator	First operand type	Second operand type	Result type
==	bits(N)	integer	boolean
		bits(N)	
	integer	integer	
	real	real	
	enumeration	enumeration	
	boolean	boolean	

**Table K10-2 Result and operand types permitted for binary operators (continued)**

Operator	First operand type	Second operand type	Result type
!=	bits(N)	bits(N)	boolean
	integer	integer	
	real	real	
<, >	integer	integer	boolean
<=, >=	real	real	
+, -	integer	integer	integer
	real	real	real
	bits(N)	bits(N) integer	bits(N)
<<, >>	integer	integer	integer
*	integer	integer	integer
	real	real	real
	bits(N)	bits(N)	bits(N)
/	real	real	real
DIV	integer	integer	integer
MOD	integer	integer	integer
	bits(N)	integer	
&&,	boolean	boolean	boolean
AND, OR, EOR	bits(N)	bits(N)	bits(N)
^	integer	integer	integer
	real	integer	real

## K10.5 Statements and control structures

This section describes the statements and program structures available in the pseudocode:

- [Statements and Indentation](#).
- [Function and procedure calls](#).
- [Conditional control structures](#) on page K10-6270.
- [Loop control structures](#) on page K10-6271.
- [Special statements](#) on page K10-6272.
- [Comments](#) on page K10-6272.

### K10.5.1 Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements contained in structures such as if ... then ... else ... or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

### K10.5.2 Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.

## Procedure and function definitions

A procedure definition has the form:

```
<procedure name>(<argument prototypes>)
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
```

where <argument prototypes> consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

---

### Note

---

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

---

A function definition is similar, but also declares the return type of the function:

```
<return type> <function name>(<argument prototypes>)
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
```

---

### Note

---

A function or procedure name can include a ".". This is a convention used for functions that have similar but different behaviors in AArch32 and AArch64 states.

---

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

```
<return type> <function name>[<argument prototypes>]
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
```

Its related function definition with no return type is equivalent to writing to an array. For example:

```
<function name>[<argument prototypes>] = <value prototype>
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
```

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

## Procedure calls

A procedure call has the form:

```
<procedure_name>(<arguments>);
```

## Return statements

A procedure return has the form:

```
return;
```

A function return has the form:

```
return <expression>;
```

where <expression> is of the type declared in the function prototype line.

### K10.5.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

#### if ... then ... else ...

In addition to being a ternary operator, a multi-line if ... then ... else ... structure can act as a control structure and has the form:

```
if <boolean_expression> then
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;

elsif <boolean_expression> then
    <statement a>;
    <statement b>;
    ...
    <statement z>;
else
    <statement A>;
    <statement B>;
    ...
    <statement Z>;
```

The block of lines consisting of `elsif` and its indented statements is optional, and multiple `elsif` blocks can be used.

The block of lines consisting of `else` and its indented statements is optional.

Abbreviated one-line forms can be used when the `then` part, and in the `else` part if it is present, contain only simple statements such as:

```
if <boolean_expression> then <statement 1>;
if <boolean_expression> then <statement 1>; else <statement A>;
if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>;
```

#### ————— Note —————

In these forms, <statement 1>, <statement 2> and <statement A> must be terminated by semicolons. This and the fact that the `else` part is optional distinguish its use as a control structure from its use as a ternary operator.

#### case ... of ...

A case ... of ... structure has the form:

```
case <expression> of
    when <literal values1>
        <statement 1>;
        <statement 2>;
        ...
        <statement n>;

    when <literal values2>
        <statement 1>;
        <statement 2>;
        ...
        <statement n>;

    ... more "when" groups if required ...
```

```
otherwise
    <statement A>;
    <statement B>;
    ...
    <statement Z>;
```

In this structure, <literal values1> and <literal values2> consist of literal values of the same type as <expression>, separated by commas. There can be additional when groups in the structure. Abbreviated one line forms of when and otherwise parts can be used when they contain only simple statements.

If <expression> has a bitstring type, the literal values can also include bitstring literals containing 'x' bits, known as bitmasks. For details see [Equality and non-equality on page K10-6262](#).

## K10.5.4 Loop control structures

This section describes the three loop control structures used in the pseudocode.

### repeat ... until ...

A repeat ... until ... structure has the form:

```
repeat
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
until <boolean_expression>;
```

It executes the statement block at least once, and the loop repeats until <boolean expression> evaluates to TRUE. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

### while ... do

A while ... do structure has the form:

```
while <boolean_expression> do
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
```

It begins executing the statement block only if the Boolean expression is true. The loop then runs until the expression is false.

### for ...

A for ... structure has the form:

```
for <assignable_expression> = <integer_expr1> to <integer_expr2>
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
```

The <assignable\_expression> is initialized to <integer\_expr1> and compared to <integer\_expr2>. If <integer\_expr1> is less than <integer\_expr2>, the loop body is executed and the <assignable\_expression> incremented by one. This repeats until <assignable expression> is more than or equal to <integer\_expr2>.

There is an alternate form:

```
for <assignable_expression> = <integer_expr1> downto <integer_expr2>
```

where <integer\_expr1> is decremented after the loop body executes and continues until <assignable expression> is less than or equal than <integer\_expr2>.

## K10.5.5 Special statements

This section describes statements with particular architecturally-defined behaviors.

### UNDEFINED

This subsection describes the statement:

UNDEFINED;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

### UNPREDICTABLE

This subsection describes the statement:

UNPREDICTABLE;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

### SEE...

This subsection describes the statement:

SEE <reference>;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The <reference> indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

### IMPLEMENTATION\_DEFINED

This subsection describes the statement:

IMPLEMENTATION\_DEFINED {"<text>"};

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION\_DEFINED. An optional <text> field can give more information.

## K10.5.6 Comments

The pseudocode supports two styles of comments:

- // starts a comment that is terminated by the end of the line.
- /\* starts a comment that is terminated by \*/.

/\*\*/ statements might not be nested, and the first \*/ ends the comment.

### ————— Note —————

Comment lines do not require a terminating semicolon.

## K10.6 Built-in functions

This section describes:

- [Bitstring manipulation functions.](#)
- [Arithmetic functions on page K10-6274.](#)

### K10.6.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

#### Bitstring length and most significant bit

If  $x$  is a bitstring:

- The bitstring length function  $\text{Len}(x)$  returns the length of  $x$  as an integer.

#### Bitstring concatenation and replication

If  $x$  is a bitstring and  $n$  is an integer with  $n \geq 0$ :

- $\text{Replicate}(x, n)$  is the bitstring of length  $n \cdot \text{Len}(x)$  consisting of  $n$  copies of  $x$  concatenated together.
- $\text{Zeros}(n) = \text{Replicate}('0', n)$ .
- $\text{Ones}(n) = \text{Replicate}('1', n)$ .

#### Bitstring count

If  $x$  is a bitstring,  $\text{BitCount}(x)$  is an integer result equal to the number of bits of  $x$  that are ones.

## Testing a bitstring for being all zero or all ones

If  $x$  is a bitstring:

- $\text{IsZero}(x)$  produces TRUE if all of the bits of  $x$  are zeros and FALSE if any of them are ones
- $\text{IsZeroBit}(x)$  produces '1' if all of the bits of  $x$  are zeros and '0' if any of them are ones.

$\text{IsOnes}(x)$  and  $\text{IsOnesBit}(x)$  work in the corresponding ways. This means:

```
IsZero(x)    = (BitCount(x) == 0)
IsOnes(x)    = (BitCount(x) == Len(x))
IsZeroBit(x) = if IsZero(x) then '1' else '0'
IsOnesBit(x) = if IsOnes(x) then '1' else '0'
```

## Lowest and highest set bits of a bitstring

If  $x$  is a bitstring, and  $N = \text{Len}(x)$ :

- $\text{LowestSetBit}(x)$  is the minimum bit number of any of the bits of  $x$  that are ones. If all of its bits are zeros,  $\text{LowestSetBit}(x) = N$ .
- $\text{HighestSetBit}(x)$  is the maximum bit number of any of the bits of  $x$  that are ones. If all of its bits are zeros,  $\text{HighestSetBit}(x) = -1$ .
- $\text{CountLeadingZeroBits}(x)$  is the number of zero bits at the left end of  $x$ , in the range 0 to  $N$ . This means:  
 $\text{CountLeadingZeroBits}(x) = N - 1 - \text{HighestSetBit}(x)$ .
- $\text{CountLeadingSignBits}(x)$  is the number of copies of the sign bit of  $x$  at the left end of  $x$ , excluding the sign bit itself, and is in the range 0 to  $N-1$ . This means:  
 $\text{CountLeadingSignBits}(x) = \text{CountLeadingZeroBits}(x \ll N-1:1 \gg \text{EOR } x \ll N-2:0 \gg)$ .

## Zero-extension and sign-extension of bitstrings

If  $x$  is a bitstring and  $i$  is an integer, then  $\text{ZeroExtend}(x, i)$  is  $x$  extended to a length of  $i$  bits, by adding sufficient zero bits to its left. That is, if  $i = \text{Len}(x)$ , then  $\text{ZeroExtend}(x, i) = x$ , and if  $i > \text{Len}(x)$ , then:

```
ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x
```

If  $x$  is a bitstring and  $i$  is an integer, then  $\text{SignExtend}(x, i)$  is  $x$  extended to a length of  $i$  bits, by adding sufficient copies of its leftmost bit to its left. That is, if  $i = \text{Len}(x)$ , then  $\text{SignExtend}(x, i) = x$ , and if  $i > \text{Len}(x)$ , then:

```
SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x
```

It is a pseudocode error to use either  $\text{ZeroExtend}(x, i)$  or  $\text{SignExtend}(x, i)$  in a context where it is possible that  $i < \text{Len}(x)$ .

## Converting bitstrings to integers

If  $x$  is a bitstring,  $\text{SInt}()$  is the integer whose two's complement representation is  $x$ .

$\text{UInt}()$  is the integer whose unsigned representation is  $x$ .

$\text{Int}(x, \text{unsigned})$  returns either  $\text{SInt}(x)$  or  $\text{UInt}(x)$  depending on the value of its second argument.

### K10.6.2 Arithmetic functions

This section defines built-in arithmetic functions.

#### Absolute value

If  $x$  is either of type real or integer,  $\text{Abs}(x)$  returns the absolute value of  $x$ . The result is the same type as  $x$ .

## Rounding and aligning

If  $x$  is a real:

- $\text{RoundDown}(x)$  produces the largest integer  $n$  such that  $n \leq x$ .
- $\text{RoundUp}(x)$  produces the smallest integer  $n$  such that  $n \geq x$ .
- $\text{RoundTowardsZero}(x)$  produces:
  - $\text{RoundDown}(x)$  if  $x > 0.0$ .
  - $0$  if  $x == 0.0$ .
  - $\text{RoundUp}(x)$  if  $x < 0.0$ .

If  $x$  and  $y$  are both of type integer,  $\text{Align}(x, y) = y * (x \text{ DIV } y)$ , and is of type integer.

If  $x$  is of type bitstring and  $y$  is of type integer,  $\text{Align}(x, y) = (\text{Align}(\text{UInt}(x), y)) < \text{Len}(x) - 1 : 0 >$ , and is a bitstring of the same length as  $x$ .

It is a pseudocode error to use either form of  $\text{Align}(x, y)$  in any context where  $y$  can be 0. In practice,  $\text{Align}(x, y)$  is only used with  $y$  a constant power of two, and the bitstring form used with  $y = 2^n$  has the effect of producing its argument with its  $n$  low-order bits forced to zero.

## Maximum and minimum

If  $x$  and  $y$  are integers or reals, then  $\text{Max}(x, y)$  and  $\text{Min}(x, y)$  are their maximum and minimum respectively.  $x$  and  $y$  must both be of type integer or of type real. The function returns a value of the same type as its operands.

## K10.7 Miscellaneous helper procedures and functions

This section lists the prototypes of miscellaneous *helper* procedures and functions used by the pseudocode, together with a brief description of the effect of the procedure or function. The pseudocode does not define the operation of these helper procedures and functions.

---

**Note**

[Chapter J1 ARMv8 Pseudocode](#) also has an entry for each of these functions, but currently these entries do not say anything about the effect of the function. When this information is added in [Chapter J1](#) this section will be removed from the manual.

---

### K10.7.1 EndOfInstruction()

This procedure terminates processing of the current instruction.

```
EndOfInstruction();
```

### K10.7.2 Hint\_Debug()

This procedure supplies a hint to the debug system.

```
Hint_Debug(bits(4) option);
```

### K10.7.3 Hint\_PreloadData()

This procedure performs a *preload data* hint.

```
Hint_PreloadData(bits(32) address);
```

### K10.7.4 Hint\_PreloadDataForWrite()

This procedure performs a *preload data* hint with a probability that the use will be for a write.

```
Hint_PreloadDataForWrite(bits(32) address);
```

### K10.7.5 Hint\_PreloadInstr()

This procedure performs a *preload instructions* hint.

```
Hint_PreloadInstr(bits(32) address);
```

### K10.7.6 Hint\_Yield()

This procedure performs a *Yield* hint.

```
Hint_Yield();
```

### K10.7.7 IsExternalAbort()

This function returns TRUE if the abort currently being processed is an external abort and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsExternalAbort(Fault type)  
    assert type != Fault_None;
```

```
boolean IsExternalAbort(FaultRecord fault);
```

### K10.7.8 IsAsyncAbort()

This function returns TRUE if the abort currently being processed is an asynchronous abort, and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsAsyncAbort(Fault type)
    assert type != Fault_None;

boolean IsAsyncAbort(FaultRecord fault);
```

### K10.7.9 LSInstructionSyndrome()

This function returns the extended syndrome information for a fault reported in the [HSR](#).

```
bits(11) LSInstructionSyndrome();
```

### K10.7.10 ProcessorID()

This function returns an integer that uniquely identifies the executing PE in the system.

```
integer ProcessorID();
```

### K10.7.11 RemapRegsHaveResetValues()

This function returns TRUE if the remap registers PRRR and NMRR have their IMPLEMENTATION DEFINED reset values, and FALSE otherwise.

```
boolean RemapRegsHaveResetValues();
```

### K10.7.12 ResetControlRegisters()

This function resets the System registers and memory-mapped control registers that have architecturally-defined reset values to those values. For more information about the affected registers see:

- [PE state on reset to AArch64 state on page D1-1796.](#)
- [PE state on reset into AArch32 state on page G1-4400.](#)

```
AArch64.ResetControlRegisters(boolean ResetIsCold)
AArch32.ResetControlRegisters(boolean ResetIsCold)
```

### K10.7.13 ThisInstr()

This function returns the bitstring encoding of the currently-executing instruction.

```
bits(32) ThisInstr();
```

———— **Note** ————

Currently, this function is used only on 32-bit instruction encodings.

### K10.7.14 ThisInstrLength()

This function returns the length, in bits, of the current instruction. This means it returns 32 or 16:

```
integer ThisInstrLength();
```

## K10.8 ARM pseudocode definition index

This section contains the following tables:

- [Table K10-3](#) which contains the pseudocode data types.
- [Table K10-4](#) which contains the pseudocode operators.
- [Table K10-5 on page K10-6279](#) which contains the pseudocode keywords and control structures.
- [Table K10-6 on page K10-6280](#) which contains the statements with special behaviors.

**Table K10-3 Index of pseudocode data types**

Keyword	Meaning
array	Type name for the array type
bit	Keyword equivalent to bits(1)
bits(N)	Type name for the bitstring of length N data type
boolean	Type name for the Boolean data type
enumeration	Keyword to define a new enumeration type
integer	Type name for the integer data type
real	Type name for the real data type
type	Keyword to define a new structure

**Table K10-4 Index of pseudocode operators**

Operator	Meaning
-	Unary minus on integers or reals
	Subtraction of integers, reals and bitstrings
	Used in the left-hand side of an assignment or a tuple to discard the result
+	Unary plus on integers or reals
	Addition of integers, reals and bitstrings
.	Extract named member from a list
	Extract named bit or field from a register
:	Bitstring concatenation
	Integer range in bitstring extraction operator
!	Boolean NOT
!=	Comparison for inequality
(...)	Around arguments of procedure or function
[...]	Around array index
	Around arguments of array-like function
*	Multiplication of integers, reals, and bitstrings
/	Division of reals

**Table K10-4 Index of pseudocode operators (continued)**

Operator	Meaning
&&	Boolean AND
<	<i>Less than</i> comparison of integers and reals
<...>	Slicing of specified bits of bitstring or integer
<<	Multiply integer by power of 2
<=	<i>Less than or equal</i> comparison of integers and reals
=	Assignment operator
==	Comparison for equality
>	<i>Greater than</i> comparison of integers and reals
>=	<i>Greater than or equal</i> comparison of integers and reals
>>	Divide integer by power of 2
	Boolean OR
^	Exponential operator
AND	Bitwise AND of bitstrings
DIV	Quotient from integer division
EOR	Bitwise EOR of bitstrings
IN	Tests membership of a certain expression in a set of values
MOD	Remainder from integer division
NOT	Bitwise inversion of bitstrings
OR	Bitwise OR of bitstrings

**Table K10-5 Index of pseudocode keywords and control structures**

Operator	Meaning
/*...*/	Comment delimiters
//	Introduces comment terminated by end of line
case ... of ...	Control structure for the
FALSE	One of two values a Boolean can take (other than TRUE)
for ... = ...to ...	Loop control structure, counting up from the initial value to the upper limit
for ... = ... downto ...	Loop control structure, counting down from the initial value to the lower limit
if ... then ... else ...	Condition expression selecting between two values
if ... then ... else ...	Conditional control structure
otherwise	Introduces default case in case ... of ... control structure

**Table K10-5 Index of pseudocode keywords and control structures (continued)**

Operator	Meaning
repeat ... until ...	Loop control structure that runs at least once until the termination condition is satisfied
return	Procedure or function return
TRUE	One of two values a Boolean can take (other than FALSE)
when	Introduces specific case in case ... of ... control structure
while ... do ...	Loop control structure that runs until the termination condition is satisfied

**Table K10-6 Index of special statements**

Keyword	Meaning
IMPLEMENTATION_DEFINED	Describes IMPLEMENTATION_DEFINED behavior
SEE	Points to other pseudocode to use instead
UNDEFINED	Cause Undefined Instruction exception
UNKNOWN	Unspecified value
UNPREDICTABLE	Unspecified behavior

# Appendix K11

## Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

- *Introduction and register disambiguation on page K11-6282.*
- *Alphabetical index of AArch64 registers and system instructions on page K11-6287.*
- *Functional index of AArch64 registers and system instructions on page K11-6296.*
- *Alphabetical index of AArch32 registers and system instructions on page K11-6306.*
- *Functional index of AArch32 registers and system instructions on page K11-6314.*
- *Alphabetical index of memory-mapped registers on page K11-6324.*
- *Functional index of memory-mapped registers on page K11-6329.*

## K11.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a *general name*, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 System registers or AArch64 System registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception. level suffix, \_EL0, \_EL1, \_EL2, or \_EL3.

The following sections disambiguate the general register names:

- [Register name disambiguation by Execution state.](#)
- [Register name disambiguation by Exception level on page K11-6285.](#)

### K11.1.1 Register name disambiguation by Execution state

[Table K11-1](#) disambiguates the general names of the registers by Execution state.

**Table K11-1 Disambiguation of general names of registers by Execution state**

General name	Short description	AArch64 register	AArch32 register
CONTEXTIDR	Context ID	CONTEXTIDR_EL1	CONTEXTIDR
DBGBCR	Debug Breakpoint Control Registers	DBGBCR<n>_EL1	DBGBCR<n>
DBGBVR	Debug Breakpoint Value Registers	DBGBVR<n>_EL1	DBGBVR<n> DBGXVR<n>
DBGCLAIMCLR	Debug CLAIM Tag Clear register	DBGCLAIMCLR_EL1	DBGCLAIMCLR
DBGCLAIMSET	Debug CLAIM Tag Set register	DBGCLAIMSET_EL1	DBGCLAIMSET
DBGDTRRX	Debug Data Transfer Register, Receive	DBGDTRRX_EL0	DBGDTRRXint
DBGDTRTX	Debug Data Transfer Register, Transmit	DBGDTRTX_EL0	DBGDTRTXint
DBGPRCR	Debug Power Control Register	DBGPRCR_EL1	DBGPRCR
DBGVCR	Debug Vector Catch Register	DBGVCR32_EL2	DBGVCR
DBGWCR	Debug Watchpoint Control Registers	DBGWCR<n>_EL1	DBGWCR<n>
DBGWVR	Debug Watchpoint Value Registers	DBGWVR<n>_EL1	DBGWVR<n>
DCCINT	Debug Comms Channel Interrupt Enable Register	MDCCINT_EL1	DBGDCCINT
DCCSR	Debug Comms Channel Status Register	MDCCSR_EL0	DBGDSCRint
DBGAUTHSTATUS	Debug Authentication Status	DBGAUTHSTATUS_EL1	DBGAUTHSTATUS
DLR	Debug Link Register	DLR_EL0[31:0]	DLR
DSCR	Debug System Control Register	MDSCR_EL1	DBGDSCRext
DSPSR	Debug Saved PE State Register	DSPSR_EL0	DSPSR
FAR	Fault Address Register	FAR_EL1 FAR_EL2 FAR_EL3 HPFAR_EL2	DFAR, IFAR HDFAR, HIFAR FAR_EL3 HPFAR

**Table K11-1 Disambiguation of general names of registers by Execution state (continued)**

General name	Short description	AArch64 register	AArch32 register
HCR	Hypervisor Configuration Register	HCR_EL2	HCR HCR2
HDCR	Hyp or EL2 Debug Control Register	MDCR_EL2	HDCR
HSCTLR	Hypervisor System Control Register	SCTLR_EL2	HSCTLR
HTTBR	EL2 Translation Table Base Register	TTBR0_EL2	HTTBR
ISR	Interrupt Status Register	ISR_EL1	ISR
MPIDR	Multiprocessor Affinity Register	MPIDR_EL1	MPIDR
OSDLR	OS Double-Lock Register	OSDLR_EL1	DBGOSDLR
OSDTRRX	OS Lock Data Transfer Register, Receive	OSDTRRX_EL1	DBGDTRRXext
OSDTRTX	OS Lock Data Transfer Register, Transmit	OSDTRTX_EL1	DBGDTRTXext
OSECCR	OS Lock Exception Catch Control Register	OSECCR_EL1	DBGOSECCR
OSLAR	OS Lock Access Register	OSLAR_EL1	DBGOSLAR
OSLSR	OS Lock Status Register	OSLSR_EL1	DBGOSLSR
SCR	Secure Configuration Register	SCR_EL3	SCR
SCTLR	System Control Register	SCTLR_EL1 SCTLR_EL2 SCTLR_EL3	SCTLR (NS) HSCTLR SCTLR (S)
SDCR	Secure or EL3 Debug Configuration Register	MDCR_EL3	SDCR
SDER	Secure Debug Enable Register	SDER32_EL3	SDER
SPSR	Saved Program Status Register	SPSR_EL1 SPSR_EL2 SPSR_EL3	SPSR (general description) SPSR_abt SPSR_fiq SPSR_hyp SPSR_irq SPSR_mon SPSR_svc SPSR_und
TCR	Translation Control Register	TCR_EL1 TCR_EL2 TCR_EL3 VTCR_EL2	TTBCR(NS) HTCR TTBCR(S) VTCR
TTBR	Translation Table Base Register	TTBR0_EL1 TTBR0_EL2 TTBR0_EL3 TTBR1_EL1 VTTBR_EL2	TTBR0 TTBR1 HTTBR VTTBR

**Table K11-1 Disambiguation of general names of registers by Execution state (continued)**

General name	Short description	AArch64 register	AArch32 register
VCR	PL1&0 stage 2 Translation Control Register	<a href="#">VTCR_EL2</a>	<a href="#">VTCR</a>
VBAR	Vector Base Address Register	<a href="#">VBAR_EL1</a> <a href="#">VBAR_EL2</a> <a href="#">VBAR_EL3</a>	<a href="#">VBAR</a> <a href="#">HVBAR</a> <a href="#">MVBAR</a>
VTTBR	PL1&0 stage 2 Translation Table Base Register	<a href="#">VTTBR_EL2</a>	<a href="#">VTTBR</a>

[Table K11-2](#) disambiguates the general names of the System registers that provide access to the Performance Monitors by Execution state.

**Table K11-2 Disambiguation of general names of the Performance Monitors System registers by Execution state**

General name	Short description	AArch64 register	AArch32 register
PMCCFILTR	Cycle Count Filter Register	<a href="#">PMCCFILTR_EL0</a>	<a href="#">PMCCFILTR</a>
PMCCNTR	Cycle Count Register	<a href="#">PMCCNTR_EL0</a>	<a href="#">PMCCNTR</a>
PMCEID0	Performance Monitors Cycle Count Filter Register 0	<a href="#">PMCEID0_EL0</a>	<a href="#">PMCEID0</a>
PMCEID1	Performance Monitors Cycle Count Filter Register 1	<a href="#">PMCEID1_EL0</a>	<a href="#">PMCEID1</a>
PMCNTENCLR	Performance Monitors Count Enable Clear register	<a href="#">PMCNTENCLR_EL0</a>	<a href="#">PMINTENCLR</a>
PMCNTENSET	Performance Monitors Count Enable Set register	<a href="#">PMCNTENSET_EL0</a>	<a href="#">PMCNTENSET</a>
PMCR	Performance Monitors Control Register	<a href="#">PMCR_EL0</a>	<a href="#">PMCR</a>
PMEVCNTR<n>	Performance Monitors Event Count Registers, n = 0-30	<a href="#">PMEVCNTR&lt;n&gt;_EL0</a>	<a href="#">PMEVCNTR&lt;n&gt;</a>
PMEVTYPER<n>	Performance Monitors Event Type Registers, n = 0-30	<a href="#">PMEVTYPER&lt;n&gt;_EL0</a>	<a href="#">PMEVTYPER&lt;n&gt;</a>
PMINTENCLR	Performance Monitors Interrupt Enable Clear register	<a href="#">PMINTENCLR_EL1</a>	<a href="#">PMINTENCLR</a>
PMINTENSET	Performance Monitors Interrupt Enable Set register	<a href="#">PMINTENSET_EL1</a>	<a href="#">PMINTENSET</a>
PMOVSCLR	Performance Monitors Overflow Flag Status Register	<a href="#">PMOVSCLR_EL0</a>	<a href="#">PMOVSR</a>
PMOVSSET	Performance Monitors Overflow Flag Status Set register	<a href="#">PMOVSSET_EL0</a>	<a href="#">PMOVSSET</a>
PMSELR	Performance Monitors Event Counter Selection Register	<a href="#">PMSELR_EL0</a>	<a href="#">PMSELR</a>
PMSWINC	Performance Monitors Software Increment register	<a href="#">PMSWINC_EL0</a>	<a href="#">PMSWINC</a>
PMUSERENR	Performance Monitors User Enable Register	<a href="#">PMUSERENR_EL0</a>	<a href="#">PMUSERENR</a>
PMXEVCNTR	Performance Monitors Selected Event Count Register	<a href="#">PMXEVCNTR_EL0</a>	<a href="#">PMXEVCNTR</a>
PMXEVTYPER	Performance Monitors Selected Event Type Register	<a href="#">PMXEVTYPER_EL0</a>	<a href="#">PMXEVTYPER</a>

Table K11-3 disambiguates the general names of the System registers that provide access to the Performance Monitors by Execution state.

**Table K11-3 Disambiguation of general names of the Generic Timer System registers by Execution state**

General name	Short description	AArch64 register	AArch32 register
CNTFRQ	Counter-timer Frequency register	CNTFRQ_EL0	CNTFRQ
CNTHCTL	Counter-timer Hypervisor Control register	CNTHCTL_EL2	CNTHCTL
CNTHP_CTL	Counter-timer Hypervisor Physical Timer Control register	CNTHP_CTL_EL2	CNTHP_CTL
CNTHP_CVAL	Counter-timer Hypervisor Physical Timer CompareValue register	CNTHP_CVAL_EL2	CNTHP_CVAL
CNTHP_TVAL	Counter-timer Hypervisor Physical Timer TimerValue register	CNTHP_TVAL_EL2	CNTHP_TVAL
CNTKCTL	Counter-timer Kernel Control register	CNTKCTL_EL1	CNTKCTL
CNTP_CTL	Counter-timer Physical Timer Control register	CNTP_CTL_EL0	CNTP_CTL
CNTP_CVAL	Counter-timer Physical Timer CompareValue register	CNTP_CVAL_EL0	CNTP_CVAL
CNTP_TVAL	Counter-timer Physical Timer TimerValue register	CNTP_TVAL_EL0	CNTP_TVAL
CNTPCT	Counter-timer Physical Count register	CNTPCT_EL0	CNTPCT
CNTPS_CTL	Counter-timer Physical Secure Timer Control register	CNTPS_CTL_EL1	-
CNTPS_CVAL	Counter-timer Physical Secure Timer CompareValue register	CNTPS_CVAL_EL1	-
CNTPS_TVAL	Counter-timer Physical Secure Timer TimerValue register	CNTPS_TVAL_EL1	-
CNTV_CTL	Counter-timer Virtual Timer Control register	CNTV_CTL_EL0	CNTV_CTL
CNTV_CVAL	Counter-timer Virtual Timer CompareValue register	CNTV_CVAL_EL0	CNTV_CVAL
CNTV_TVAL	Counter-timer Virtual Timer TimerValue register	CNTV_TVAL_EL0	CNTV_TVAL
CNTVCT	Counter-timer Virtual Count register	CNTVCT_EL0	CNTVCT
CNTVOFF	Counter-timer Virtual Offset register	CNTVOFF_EL2	CNTVOFF

## K11.1.2 Register name disambiguation by Exception level

Table K11-4 disambiguates the general names of the AArch64 System registers by Exception level.

**Table K11-4 Disambiguation of AArch64 System registers by Exception level**

General form	EL0	EL1	EL2	EL3
AFSR0_ELx	-	AFSR0_EL1	AFSR0_EL2	AFSR0_EL3
AFSR1_ELx	-	AFSR1_EL1	AFSR1_EL2	AFSR1_EL3
CONTEXTIDR_ELx	-	CONTEXTIDR_EL1	-	-
CPTR_ELx	-	-	CPTR_EL2	CPTR_EL3
ELR_ELx	-	ELR_EL1	ELR_EL2	ELR_EL3
ESR_ELx	-	ESR_EL1	ESR_EL2	ESR_EL3
FAR_ELx	-	FAR_EL1	FAR_EL2	FAR_EL3

**Table K11-4 Disambiguation of AArch64 System registers by Exception level (continued)**

General form	EL0	EL1	EL2	EL3

## K11.3 Functional index of AArch64 registers and system instructions

This section is an index of the AArch64 registers and system instructions, divided by functional group.

### K11.3.1 Special-purpose registers

This section is an index to the registers in the Special-purpose registers functional group.

**Table K11-6 Special-purpose registers**

Register	Description, see
DLR_EL0	<a href="#">DLR_EL0</a>
DSPSR_EL0	<a href="#">DSPSR_EL0</a>
ELR_EL1	<a href="#">ELR_EL1</a>
ELR_EL2	<a href="#">ELR_EL2</a>
ELR_EL3	<a href="#">ELR_EL3</a>
FPCR	<a href="#">FPCR</a>
FPSR	<a href="#">FPSR</a>
SP_EL0	<a href="#">SP_EL0</a>
SP_EL1	<a href="#">SP_EL1</a>
SP_EL2	<a href="#">SP_EL2</a>
SP_EL3	<a href="#">SP_EL3</a>
SPSR_abt	<a href="#">SPSR_abt</a>
SPSR_EL1	<a href="#">SPSR_EL1</a>
SPSR_EL2	<a href="#">SPSR_EL2</a>
SPSR_EL3	<a href="#">SPSR_EL3</a>
SPSR_fiq	<a href="#">SPSR_fiq</a>
SPSR_irq	<a href="#">SPSR_irq</a>
SPSR_und	<a href="#">SPSR_und</a>

### K11.3.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

**Table K11-7 VMSA-specific registers**

Register	Description, see
AMAIR_EL1	<a href="#">AMAIR_EL1</a>
AMAIR_EL2	<a href="#">AMAIR_EL2</a>
AMAIR_EL3	<a href="#">AMAIR_EL3</a>
CONTEXTIDR_EL1	<a href="#">CONTEXTIDR_EL1</a>

**Table K11-7 VMSA-specific registers (continued)**

Register	Description, see
CONTEXTIDR_EL2	<a href="#">CONTEXTIDR_EL2</a>
DACR32_EL2	<a href="#">DACR32_EL2</a>
LORC_EL1	<a href="#">LORC_EL1</a>
LOREA_EL1	<a href="#">LOREA_EL1</a>
LORID_EL1	<a href="#">LORID_EL1</a>
LORN_EL1	<a href="#">LORN_EL1</a>
LORSA_EL1	<a href="#">LORSA_EL1</a>
MAIR_EL1	<a href="#">MAIR_EL1</a>
MAIR_EL2	<a href="#">MAIR_EL2</a>
MAIR_EL3	<a href="#">MAIR_EL3</a>
TCR_EL1	<a href="#">TCR_EL1</a>
TCR_EL2	<a href="#">TCR_EL2</a>
TCR_EL3	<a href="#">TCR_EL3</a>
TTBR0_EL1	<a href="#">TTBR0_EL1</a>
TTBR0_EL2	<a href="#">TTBR0_EL2</a>
TTBR0_EL3	<a href="#">TTBR0_EL3</a>
TTBR1_EL1	<a href="#">TTBR1_EL1</a>
TTBR1_EL2	<a href="#">TTBR1_EL2</a>
VTCR_EL2	<a href="#">VTCR_EL2</a>
VTTBR_EL2	<a href="#">VTTBR_EL2</a>

### K11.3.3 ID registers

This section is an index to the registers in the Identification registers functional group.

**Table K11-8 ID registers**

Register	Description, see
AIDR_EL1	<a href="#">AIDR_EL1</a>
CCSIDR_EL1	<a href="#">CCSIDR_EL1</a>
CLIDR_EL1	<a href="#">CLIDR_EL1</a>
CSSELR_EL1	<a href="#">CSSELR_EL1</a>
CTR_EL0	<a href="#">CTR_EL0</a>
DCZID_EL0	<a href="#">DCZID_EL0</a>
ID_AA64AFR0_EL1	<a href="#">ID_AA64AFR0_EL1</a>

VPIDR_EL2	<a href="#">VPIDR_EL2</a>

#### K11.3.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

**Table K11-9 Performance monitors registers**

Register	Description, see
PMCCFILTR_EL0	<a href="#">PMCCFILTR_EL0</a>
PMCCNTR_EL0	<a href="#">PMCCNTR_EL0</a>
PMCEID0_EL0	<a href="#">PMCEID0_EL0</a>
PMCEID1_EL0	<a href="#">PMCEID1_EL0</a>
PMCNTENCLR_EL0	<a href="#">PMCNTENCLR_EL0</a>
PMCNTENSET_EL0	<a href="#">PMCNTENSET_EL0</a>
PMCR_EL0	<a href="#">PMCR_EL0</a>
PMEVCNTR<n>_EL0	<a href="#">PMEVCNTR&lt;n&gt;_EL0</a>
PMEVTYPER<n>_EL0	<a href="#">PMEVTYPER&lt;n&gt;_EL0</a>
PMINTENCLR_EL1	<a href="#">PMINTENCLR_EL1</a>
PMINTENSET_EL1	<a href="#">PMINTENSET_EL1</a>
PMOVSCLR_EL0	<a href="#">PMOVSCLR_EL0</a>
PMOVSSET_EL0	<a href="#">PMOVSSET_EL0</a>
PMSELR_EL0	<a href="#">PMSELR_EL0</a>
PMSWINC_EL0	<a href="#">PMSWINC_EL0</a>
PMUSERENR_EL0	<a href="#">PMUSERENR_EL0</a>
PMXEVCNTR_EL0	<a href="#">PMXEVCNTR_EL0</a>
PMXEVTYPER_EL0	<a href="#">PMXEVTYPER_EL0</a>

### K11.3.5 Debug registers

This section is an index to the registers in the Debug registers functional group.

**Table K11-10 Debug registers**

Register	Description, see
DBGAUTHSTATUS_EL1	<a href="#">DBGAUTHSTATUS_EL1</a>
DBGBCR<n>_EL1	<a href="#">DBGBCR&lt;n&gt;_EL1</a>
DBGBVR<n>_EL1	<a href="#">DBGBVR&lt;n&gt;_EL1</a>
DBGCLAIMCLR_EL1	<a href="#">DBGCLAIMCLR_EL1</a>
DBGCLAIMSET_EL1	<a href="#">DBGCLAIMSET_EL1</a>
DBGDTR_EL0	<a href="#">DBGDTR_EL0</a>
DBGDTRRX_EL0	<a href="#">DBGDTRRX_EL0</a>
DBGDTRTX_EL0	<a href="#">DBGDTRTX_EL0</a>
DBGPRCR_EL1	<a href="#">DBGPRCR_EL1</a>
DBGVCR32_EL2	<a href="#">DBGVCR32_EL2</a>
DBGWCR<n>_EL1	<a href="#">DBGWCR&lt;n&gt;_EL1</a>
DBGWVR<n>_EL1	<a href="#">DBGWVR&lt;n&gt;_EL1</a>
DLR_EL0	<a href="#">DLR_EL0</a>
DSPSR_EL0	<a href="#">DSPSR_EL0</a>
MDCCINT_EL1	<a href="#">MDCCINT_EL1</a>
MDCCSR_EL0	<a href="#">MDCCSR_EL0</a>
MDCR_EL2	<a href="#">MDCR_EL2</a>
MDCR_EL3	<a href="#">MDCR_EL3</a>
MDRAR_EL1	<a href="#">MDRAR_EL1</a>
MDSCR_EL1	<a href="#">MDSCR_EL1</a>
OSDLR_EL1	<a href="#">OSDLR_EL1</a>
OSDTRRX_EL1	<a href="#">OSDTRRX_EL1</a>
OSDTRTX_EL1	<a href="#">OSDTRTX_EL1</a>
OSECCR_EL1	<a href="#">OSECCR_EL1</a>
OSLAR_EL1	<a href="#">OSLAR_EL1</a>
OSLSR_EL1	<a href="#">OSLSR_EL1</a>
SDER32_EL3	<a href="#">SDER32_EL3</a>

### K11.3.6 Generic timer registers

This section is an index to the registers in the Generic Timer registers functional group.

**Table K11-11 Generic timer registers**

Register	Description, see
CNTFRQ_EL0	<a href="#">CNTFRQ_EL0</a>
CNTHCTL_EL2	<a href="#">CNTHCTL_EL2</a>
CNTHP_CTL_EL2	<a href="#">CNTHP_CTL_EL2</a>
CNTHP_CVAL_EL2	<a href="#">CNTHP_CVAL_EL2</a>
CNTHP_TVAL_EL2	<a href="#">CNTHP_TVAL_EL2</a>
CNTHV_CTL_EL2	<a href="#">CNTHV_CTL_EL2</a>
CNTHV_CVAL_EL2	<a href="#">CNTHV_CVAL_EL2</a>
CNTHV_TVAL_EL2	<a href="#">CNTHV_TVAL_EL2</a>
CNTKCTL_EL1	<a href="#">CNTKCTL_EL1</a>
CNTP_CTL_EL0	<a href="#">CNTP_CTL_EL0</a>
CNTP_CVAL_EL0	<a href="#">CNTP_CVAL_EL0</a>
CNTP_TVAL_EL0	<a href="#">CNTP_TVAL_EL0</a>
CNTPCT_EL0	<a href="#">CNTPCT_EL0</a>
CNTPS_CTL_EL1	<a href="#">CNTPS_CTL_EL1</a>
CNTPS_CVAL_EL1	<a href="#">CNTPS_CVAL_EL1</a>
CNTPS_TVAL_EL1	<a href="#">CNTPS_TVAL_EL1</a>
CNTV_CTL_EL0	<a href="#">CNTV_CTL_EL0</a>
CNTV_CVAL_EL0	<a href="#">CNTV_CVAL_EL0</a>
CNTV_TVAL_EL0	<a href="#">CNTV_TVAL_EL0</a>
CNTVCT_EL0	<a href="#">CNTVCT_EL0</a>
CNTVOFF_EL2	<a href="#">CNTVOFF_EL2</a>

### K11.3.7 Cache maintenance system instructions

This section is an index to the registers in the Cache maintenance instructions functional group.

**Table K11-12 Cache maintenance system instructions**

Register	Description, see
DC C1SW	<a href="#">DC C1SW</a>
DC C1VAC	<a href="#">DC C1VAC</a>
DC C2SW	<a href="#">DC C2SW</a>
DC C2VAC	<a href="#">DC C2VAC</a>

**Table K11-12 Cache maintenance system instructions (continued)**

Register	Description, see
DC CVAP	<a href="#">DC CVAP</a>
DC CVAU	<a href="#">DC CVAU</a>
DC ISW	<a href="#">DC ISW</a>
DC IVAC	<a href="#">DC IVAC</a>
DC ZVA	<a href="#">DC ZVA</a>
IC IALLU	<a href="#">IC IALLU</a>
IC IALLUIS	<a href="#">IC IALLUIS</a>
IC IVAU	<a href="#">IC IVAU</a>

### K11.3.8 Address translation system instructions

This section is an index to the registers in the Address translation instructions functional group.

**Table K11-13 Address translation system instructions**

Register	Description, see
AT S12E0R	<a href="#">AT S12E0R</a>
AT S12E0W	<a href="#">AT S12E0W</a>
AT S12E1R	<a href="#">AT S12E1R</a>
AT S12E1W	<a href="#">AT S12E1W</a>
AT S1E0R	<a href="#">AT S1E0R</a>
AT S1E0W	<a href="#">AT S1E0W</a>
AT S1E1R	<a href="#">AT S1E1R</a>
AT S1E1RP	<a href="#">AT S1E1RP</a>
AT S1E1W	<a href="#">AT S1E1W</a>
AT S1E1WP	<a href="#">AT S1E1WP</a>
AT S1E2R	<a href="#">AT S1E2R</a>
AT S1E2W	<a href="#">AT S1E2W</a>
AT S1E3R	<a href="#">AT S1E3R</a>
AT S1E3W	<a href="#">AT S1E3W</a>

### K11.3.9 TLB maintenance system instructions

This section is an index to the registers in the TLB maintenance instructions functional group.

**Table K11-14 TLB maintenance system instructions**

Register	Description, see
TLBI ALLE1	<a href="#">TLBI ALLE1</a>
TLBI ALLE1IS	<a href="#">TLBI ALLE1IS</a>
TLBI ALLE2	<a href="#">TLBI ALLE2</a>
TLBI ALLE2IS	<a href="#">TLBI ALLE2IS</a>
TLBI ALLE3	<a href="#">TLBI ALLE3</a>

## K11.4 Alphabetical index of AArch32 registers and system instructions

This section is an index of AArch32 registers and system instructions in alphabetical order.

**Table K11-16 Alphabetical index of AArch32 Registers**

Register	Description, see
ACTLR	<a href="#">ACTLR, Auxiliary Control Register on page G6-4775</a>
ACTLR2	<a href="#">ACTLR2, Auxiliary Control Register 2 on page G6-4777</a>
ADFSR	<a href="#">ADFSR, Auxiliary Data Fault Status Register on page G6-4779</a>
AIDR	<a href="#">AIDR, Auxiliary ID Register on page G6-4781</a>
AIFSR	<a href="#">AIFSR, Auxiliary Instruction Fault Status Register on page G6-4783</a>
AMAIR0	<a href="#">AMAIR0, Auxiliary Memory Attribute Indirection Register 0 on page G6-4785</a>
AMAIR1	<a href="#">AMAIR1, Auxiliary Memory Attribute Indirection Register 1 on page G6-4787</a>
APSR	<a href="#">APSR, Application Program Status Register on page G6-4789</a>
ATS12NSOPR	<a href="#">ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read on page G6-4791</a>
ATS12NSOPW	<a href="#">ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write on page G6-4793</a>
ATS12NSOUR	<a href="#">ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read on page G6-4795</a>
ATS12NSOUW	<a href="#">ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write on page G6-4797</a>
ATS1CPR	<a href="#">ATS1CPR, Address Translate Stage 1 Current state PL1 Read on page G6-4799</a>
ATS1CPRP	<a href="#">ATS1CPRP, Address Translate Stage 1 Current state PL1 Read PAN on page G6-4801</a>
ATS1CPW	<a href="#">ATS1CPW, Address Translate Stage 1 Current state PL1 Write on page G6-4803</a>
ATS1CPWP	<a href="#">ATS1CPWP, Address Translate Stage 1 Current state PL1 Write PAN on page G6-4805</a>
ATS1CUR	<a href="#">ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read on page G6-4807</a>
ATS1CUW	<a href="#">ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write on page G6-4809</a>
ATS1HR	<a href="#">ATS1HR, Address Translate Stage 1 Hyp mode Read on page G6-4811</a>
ATS1HW	<a href="#">ATS1HW, Address Translate Stage 1 Hyp mode Write on page G6-4813</a>
BPIALL	<a href="#">BPIALL, Branch Predictor Invalidate All on page G6-4815</a>
BPIALLIS	<a href="#">BPIALLIS, Branch Predictor Invalidate All, Inner Shareable on page G6-4817</a>
BPIMVA	<a href="#">BPIMVA, Branch Predictor Invalidate by VA on page G6-4819</a>
CCSIDR	<a href="#">CCSIDR, Current Cache Size ID Register on page G6-4821</a>
CLIDR	<a href="#">CLIDR, Cache Level ID Register on page G6-4823</a>
CNTFRQ	<a href="#">CNTFRQ, Counter-timer Frequency register on page G6-5384</a>
CNTHCTL	<a href="#">CNTHCTL, Counter-timer Hyp Control register on page G6-5386</a>
CNTHP_CTL	<a href="#">CNTHP_CTL, Counter-timer Hyp Physical Timer Control register on page G6-5388</a>
CNTHP_CVAL	<a href="#">CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register on page G6-5391</a>

**Table K11-16 Alphabetical index of AArch32 Registers (continued)**

Register	Description, see
CNTHP_TVAL	<i>CNTHP_TVAL</i> , Counter-timer Hyp Physical Timer TimerValue register on page G6-5393
CNTHV_CTL	<i>CNTHV_CTL</i> , Counter-timer Virtual Timer Control register (EL2) on page G6-5395
CNTHV_CVAL	<i>CNTHV_CVAL</i> , Counter-timer Virtual Timer CompareValue register (EL2) on page G6-5398
CNTHV_TVAL	<i>CNTHV_TVAL</i> , Counter-timer Virtual Timer TimerValue register (EL2) on page G6-5400
CNTKCTL	<i>CNTKCTL</i> , Counter-timer Kernel Control register on page G6-5402
CNTP_CTL	<i>CNTP_CTL</i> , Counter-timer Physical Timer Control register on page G6-5404
CNTP_CVAL	<i>CNTP_CVAL</i> , Counter-timer Physical Timer CompareValue register on page G6-5407
CNTP_TVAL	<i>CNTP_TVAL</i> , Counter-timer Physical Timer TimerValue register on page G6-5410
CNTPCT	<i>CNTPCT</i> , Counter-timer Physical Count register on page G6-5413
CNTV_CTL	<i>CNTV_CTL</i> , Counter-timer Virtual Timer Control register on page G6-5415
CNTV_CVAL	<i>CNTV_CVAL</i> , Counter-timer Virtual Timer CompareValue register on page G6-5418
CNTV_TVAL	<i>CNTV_TVAL</i> , Counter-timer Virtual Timer TimerValue register on page G6-5420
CNTVCT	<i>CNTVCT</i> , Counter-timer Virtual Count register on page G6-5422
CNTVOFF	<i>CNTVOFF</i> , Counter-timer Virtual Offset register on page G6-5424
CONTEXTIDR	<i>CONTEXTIDR</i> , Context ID Register on page G6-4825
CP15DMB	<i>CP15DMB</i> , Data Memory Barrier System instruction on page G6-4828
CP15DSB	<i>CP15DSB</i> , Data Synchronization Barrier System instruction on page G6-4830
CP15ISB	<i>CP15ISB</i> , Instruction Synchronization Barrier System instruction on page G6-4832
CPACR	<i>CPACR</i> , Architectural Feature Access Control Register on page G6-4834
CPSR	<i>CPSR</i> , Current Program Status Register on page G6-4838
CSSELR	<i>CSSELR</i> , Cache Size Selection Register on page G6-4841
CTR	<i>CTR</i> , Cache Type Register on page G6-4843
DACR	<i>DACR</i> , Domain Access Control Register on page G6-4846
DBGAUTHSTATUS	<i>DBGAUTHSTATUS</i> , Debug Authentication Status register on page G6-5240
DBGBCR<n>	<i>DBGBCR&lt;n&gt;</i> , Debug Breakpoint Control Registers, $n = 0 - 15$ on page G6-5242
DBGBVR<n>	<i>DBGBVR&lt;n&gt;</i> , Debug Breakpoint Value Registers, $n = 0 - 15$ on page G6-5247
DBGBXVR<n>	<i>DBGBXVR&lt;n&gt;</i> , Debug Breakpoint Extended Value Registers, $n = 0 - 15$ on page G6-5250
DBGCLAIMCLR	<i>DBGCLAIMCLR</i> , Debug Claim Tag Clear register on page G6-5253
DBGCLAIMSET	<i>DBGCLAIMSET</i> , Debug Claim Tag Set register on page G6-5255
DBGDCCINT	<i>DBGDCCINT</i> , DCC Interrupt Enable Register on page G6-5257
DBGDEVID	<i>DBGDEVID</i> , Debug Device ID register 0 on page G6-5259
DBGDEVID1	<i>DBGDEVID1</i> , Debug Device ID register 1 on page G6-5262

**Table K11-16 Alphabetical index of AArch32 Registers (continued)**

VTTBR	<a href="#">VTTBR, Virtualization Translation Table Base Register on page G6-5236</a>

## K11.5 Functional index of AArch32 registers and system instructions

This section is an index of the AArch32 registers and system instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- [Special-purpose registers](#).
- [VMSA-specific registers](#) on page K11-6315.
- [ID registers](#) on page K11-6315.
- [Performance monitors registers](#) on page K11-6317.
- [Debug registers](#) on page K11-6317.
- [Generic timer registers](#) on page K11-6319.
- [Cache maintenance system instructions](#) on page K11-6319.
- [Address translation system instructions](#) on page K11-6320.
- [TLB maintenance system instructions](#) on page K11-6320.
- [Legacy feature registers and system instructions](#) on page K11-6322.
- [Base system registers](#) on page K11-6322.

### K11.5.1 Special-purpose registers

This section is an index to the registers in the Processor state registers functional group.

**Table K11-17 Special-purpose registers**

Register	Description, see
DLR	<a href="#">DLR</a>
DSPSR	<a href="#">DSPSR</a>
ELR_hyp	<a href="#">ELR_hyp</a>
FPSCR	<a href="#">FPSCR</a>
SPSR	<a href="#">SPSR</a>
SPSR_abt	<a href="#">SPSR_abt</a>
SPSR_fiq	<a href="#">SPSR_fiq</a>
SPSR_hyp	<a href="#">SPSR_hyp</a>
SPSR_irq	<a href="#">SPSR_irq</a>
SPSR_mon	<a href="#">SPSR_mon</a>
SPSR_svc	<a href="#">SPSR_svc</a>
SPSR_und	<a href="#">SPSR_und</a>

## K11.5.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

**Table K11-18 VMSA-specific registers**

Register	Description, see
AMAIRO	<a href="#">AMAIRO</a>
AMAIR1	<a href="#">AMAIR1</a>
CONTEXTIDR	<a href="#">CONTEXTIDR</a>
DACR	<a href="#">DACR</a>
HAMAIRO	<a href="#">HAMAIRO</a>
HMAIR1	<a href="#">HMAIR1</a>
HMAIRO	<a href="#">HMAIRO</a>
HMAIR1	<a href="#">HMAIR1</a>
HTCR	<a href="#">HTCR</a>
HTTBR	<a href="#">HTTBR</a>
MAIRO	<a href="#">MAIRO</a>
MAIR1	<a href="#">MAIR1</a>
NMRR	<a href="#">NMRR</a>
PRRR	<a href="#">PRRR</a>
TTBCR	<a href="#">TTBCR</a>
TTBCR2	<a href="#">TTBCR2</a>
TTBR0	<a href="#">TTBR0</a>
TTBR1	<a href="#">TTBR1</a>
VTCT	<a href="#">VTCT</a>
VTTBR	<a href="#">VTTBR</a>

## K11.5.3 ID registers

This section is an index to the registers in the Identification registers functional group.

**Table K11-19 ID registers**

Register	Description, see
AIDR	<a href="#">AIDR</a>
CCSIDR	<a href="#">CCSIDR</a>
CLIDR	<a href="#">CLIDR</a>
CSSELR	<a href="#">CSSELR</a>
CTR	<a href="#">CTR</a>

**Table K11-19 ID registers (continued)**

Register	Description, see
FPSID	<a href="#">FPSID</a>
ID_AFR0	<a href="#">ID_AFR0</a>
ID_DFR0	<a href="#">ID_DFR0</a>
ID_ISAR0	<a href="#">ID_ISAR0</a>
ID_ISAR1	<a href="#">ID_ISAR1</a>
ID_ISAR2	<a href="#">ID_ISAR2</a>
ID_ISAR3	<a href="#">ID_ISAR3</a>
ID_ISAR4	<a href="#">ID_ISAR4</a>
ID_ISAR5	<a href="#">ID_ISAR5</a>
ID_MMFR0	<a href="#">ID_MMFR0</a>
ID_MMFR1	<a href="#">ID_MMFR1</a>
ID_MMFR2	<a href="#">ID_MMFR2</a>
ID_MMFR3	<a href="#">ID_MMFR3</a>
ID_MMFR4	<a href="#">ID_MMFR4</a>
ID_PFR0	<a href="#">ID_PFR0</a>
ID_PFR1	<a href="#">ID_PFR1</a>
MIDR	<a href="#">MIDR</a>
MPIDR	<a href="#">MPIDR</a>
MVFR0	<a href="#">MVFR0</a>
MVFR1	<a href="#">MVFR1</a>
MVFR2	<a href="#">MVFR2</a>
REVIDR	<a href="#">REVIDR</a>
TCMTR	<a href="#">TCMTR</a>
TLBTR	<a href="#">TLBTR</a>
VMPIDR	<a href="#">VMPIDR</a>
VPIDR	<a href="#">VPIDR</a>

## K11.5.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

**Table K11-20 Performance monitors registers**

Register	Description, see
PMCCFILTR	<a href="#">PMCCFILTR</a>
PMCCNTR	<a href="#">PMCCNTR</a>
PMCEID0	<a href="#">PMCEID0</a>
PMCEID1	<a href="#">PMCEID1</a>
PMCEID2	<a href="#">PMCEID2</a>
PMCEID3	<a href="#">PMCEID3</a>

## K11.6 Alphabetical index of memory-mapped registers

This section is an index of memory-mapped registers in alphabetical order.

**Table K11-28 Alphabetical index of Memory-Mapped Registers**

Register	Description, see
ASICCTL	<i>ASICCTL</i> , CTI External Multiplexer Control register on page H9-5678
CNTACR<n>	<i>CNTACR&lt;n&gt;</i> , Counter-timer Access Control Registers, $n = 0 - 7$ on page I3-5817
CNTCR	<i>CNTCR</i> , Counter Control Register on page I3-5819
CNTCV	<i>CNTCV</i> , Counter Count Value register on page I3-5821
CNTEL0ACR	<i>CNTEL0ACR</i> , Counter-timer EL0 Access Control Register on page I3-5823
CNTFID0	<i>CNTFID0</i> , Counter Frequency ID on page I3-5825
CNTFID<n>	<i>CNTFID&lt;n&gt;</i> , Counter Frequency IDs, $n > 0$ on page I3-5827
CNTFRQ	<i>CNTFRQ</i> , Counter-timer Frequency on page I3-5829
CNTNSAR	<i>CNTNSAR</i> , Counter-timer Non-secure Access Register on page I3-5831
CNTP_CTL	<i>CNTP_CTL</i> , Counter-timer Physical Timer Control on page I3-5833
CNTP_CVAL	<i>CNTP_CVAL</i> , Counter-timer Physical Timer CompareValue on page I3-5835
CNTP_TVAL	<i>CNTP_TVAL</i> , Counter-timer Physical Timer TimerValue on page I3-5837
CNTPCT	<i>CNTPCT</i> , Counter-timer Physical Count on page I3-5839
CNTSR	<i>CNTSR</i> , Counter Status Register on page I3-5841
CNTTIDR	<i>CNTTIDR</i> , Counter-timer Timer ID Register on page I3-5843
CNTV_CTL	<i>CNTV_CTL</i> , Counter-timer Virtual Timer Control on page I3-5845
CNTV_CVAL	<i>CNTV_CVAL</i> , Counter-timer Virtual Timer CompareValue on page I3-5847
CNTV_TVAL	<i>CNTV_TVAL</i> , Counter-timer Virtual Timer TimerValue on page I3-5849
CNTVCT	<i>CNTVCT</i> , Counter-timer Virtual Count on page I3-5851
CNTVOFF	<i>CNTVOFF</i> {<n>}, Counter-timer Virtual Offset on page I3-5853
CNTVOFF<n>	<i>CNTVOFF</i> {<n>}, Counter-timer Virtual Offset on page I3-5853
CounterID<n>	<i>CounterID</i> <n>, Counter ID registers, $n = 0 - 11$ on page I3-5855
CTIAPPCLEAR	<i>CTIAPPCLEAR</i> , CTI Application Trigger Clear register on page H9-5679
CTIAPPPULSE	<i>CTIAPPPULSE</i> , CTI Application Pulse register on page H9-5680
CTIAPPSET	<i>CTIAPPSET</i> , CTI Application Trigger Set register on page H9-5681
CTIAUTHSTATUS	<i>CTIAUTHSTATUS</i> , CTI Authentication Status register on page H9-5682
CTICHINSTATUS	<i>CTICHINSTATUS</i> , CTI Channel In Status register on page H9-5684
CTICHOUTSTATUS	<i>CTICHOUTSTATUS</i> , CTI Channel Out Status register on page H9-5685
CTICIDR0	<i>CTICIDR0</i> , CTI Component Identification Register 0 on page H9-5686
CTICIDR1	<i>CTICIDR1</i> , CTI Component Identification Register 1 on page H9-5687

**Table K11-28 Alphabetical index of Memory-Mapped Registers (continued)**

<b>Register</b>	<b>Description, see</b>
CTICIDR2	<i>CTICIDR2, CTI Component Identification Register 2 on page H9-5688</i>
CTICIDR3	<i>CTICIDR3, CTI Component Identification Register 3 on page H9-5689</i>
CTICLAIMCLR	<i>CTICLAIMCLR, CTI Claim Tag Clear register on page H9-5690</i>
CTICLAIMSET	<i>CTICLAIMSET, CTI Claim Tag Set register on page H9-5691</i>
CTICONTROL	<i>CTICONTROL, CTI Control register on page H9-5692</i>
CTIDEVAFF0	<i>CTIDEVAFF0, CTI Device Affinity register 0 on page H9-5694</i>
CTIDEVAFF1	<i>CTIDEVAFF1, CTI Device Affinity register 1 on page H9-5695</i>
CTIDEVARCH	<i>CTIDEVARCH, CTI Device Architecture register on page H9-5696</i>
CTIDEVID	<i>CTIDEVID, CTI Device ID register 0 on page H9-5698</i>
CTIDEVID1	<i>CTIDEVID1, CTI Device ID register 1 on page H9-5700</i>
CTIDEVID2	<i>CTIDEVID2, CTI Device ID register 2 on page H9-5701</i>
CTIDEVTYPE	<i>CTIDEVTYPE, CTI Device Type register on page H9-5702</i>
CTIGATE	<i>CTIGATE, CTI Channel Gate Enable register on page H9-5703</i>
CTIINEN<n>	<i>CTIINEN&lt;n&gt;, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31 on page H9-5704</i>
CTIINTACK	<i>CTIINTACK, CTI Output Trigger Acknowledge register on page H9-5705</i>
CTIITCTRL	<i>CTIITCTRL, CTI Integration mode Control register on page H9-5707</i>
CTILAR	<i>CTILAR, CTI Lock Access Register on page H9-5709</i>
CTILSR	<i>CTILSR, CTI Lock Status Register on page H9-5710</i>
CTIOUTEN<n>	<i>CTIOUTEN&lt;n&gt;, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31 on page H9-5712</i>
CTIPIDR0	<i>CTIPIDR0, CTI Peripheral Identification Register 0 on page H9-5713</i>
CTIPIDR1	<i>CTIPIDR1, CTI Peripheral Identification Register 1 on page H9-5714</i>
CTIPIDR2	<i>CTIPIDR2, CTI Peripheral Identification Register 2 on page H9-5715</i>
CTIPIDR3	<i>CTIPIDR3, CTI Peripheral Identification Register 3 on page H9-5716</i>
CTIPIDR4	<i>CTIPIDR4, CTI Peripheral Identification Register 4 on page H9-5717</i>
CTITRIGINSTATUS	<i>CTITRIGINSTATUS, CTI Trigger In Status register on page H9-5718</i>
CTITRIGOUTSTATUS	<i>CTITRIGOUTSTATUS, CTI Trigger Out Status register on page H9-5719</i>
DBGAUTHSTATUS_EL1	<i>DBGAUTHSTATUS_EL1, Debug Authentication Status register on page H9-5578</i>
DBGBCR<n>_EL1	<i>DBGBCR&lt;n&gt;_EL1, Debug Breakpoint Control Registers, n = 0 - 15 on page H9-5580</i>
DBGBVR<n>_EL1	<i>DBGBVR&lt;n&gt;_EL1, Debug Breakpoint Value Registers, n = 0 - 15 on page H9-5584</i>
DBGCLAIMCLR_EL1	<i>DBGCLAIMCLR_EL1, Debug Claim Tag Clear register on page H9-5589</i>
DBGCLAIMSET_EL1	<i>DBGCLAIMSET_EL1, Debug Claim Tag Set register on page H9-5591</i>
DBGDTRRX_EL0	<i>DBGDTRRX_EL0, Debug Data Transfer Register; Receive on page H9-5593</i>

**Table K11-28 Alphabetical index of Memory-Mapped Registers (continued)**

<b>Register</b>	<b>Description, see</b>
DBGDTRTX_EL0	<i>DBGDTRTX_EL0, Debug Data Transfer Register, Transmit</i> on page H9-5595
DBGWCR<n>_EL1	<i>DBGWCR&lt;n&gt;_EL1, Debug Watchpoint Control Registers, n = 0 - 15</i> on page H9-5597
DBGWVR<n>_EL1	<i>DBGWVR&lt;n&gt;_EL1, Debug Watchpoint Value Registers, n = 0 - 15</i> on page H9-5600
EDAA32PFR	<i>EDAA32PFR, External Debug AArch32 Processor Feature Register</i> on page H9-5602
EDACR	<i>EDACR, External Debug Auxiliary Control Register</i> on page H9-5604
EDCIDR0	<i>EDCIDR0, External Debug Component Identification Register 0</i> on page H9-5605
EDCIDR1	<i>EDCIDR1, External Debug Component Identification Register 1</i> on page H9-5606
EDCIDR2	<i>EDCIDR2, External Debug Component Identification Register 2</i> on page H9-5607
EDCIDR3	<i>EDCIDR3, External Debug Component Identification Register 3</i> on page H9-5608
EDCIDSr	<i>EDCIDSr, External Debug Context ID Sample Register</i> on page H9-5609
EDDEVAFF0	<i>EDDEVAFF0, External Debug Device Affinity register 0</i> on page H9-5611
EDDEVAFF1	<i>EDDEVAFF1, External Debug Device Affinity register 1</i> on page H9-5612
EDDEVARCH	<i>EDDEVARCH, External Debug Device Architecture register</i> on page H9-5613
EDDEVID	<i>EDDEVID, External Debug Device ID register 0</i> on page H9-5615
EDDEVID1	<i>EDDEVID1, External Debug Device ID register 1</i> on page H9-5617
EDDEVID2	<i>EDDEVID2, External Debug Device ID register 2</i> on page H9-5618
EDDEVTYPE	<i>EDDEVTYPE, External Debug Device Type register</i> on page H9-5619
EDDFR	<i>EDDFR, External Debug Feature Register</i> on page H9-5620
EDECCR	<i>EDECCR, External Debug Exception Catch Control Register</i> on page H9-5622
EDECR	<i>EDECR, External Debug Execution Control Register</i> on page H9-5626
EDESR	<i>EDESR, External Debug Event Status Register</i> on page H9-5628
EDITCTRL	<i>EDITCTRL, External Debug Integration mode Control register</i> on page H9-5630
EDITR	<i>EDITR, External Debug Instruction Transfer Register</i> on page H9-5632
EDLAR	<i>EDLAR, External Debug Lock Access Register</i> on page H9-5634
EDLSR	<i>EDLSR, External Debug Lock Status Register</i> on page H9-5635
EDPCSR	<i>EDPCSR, External Debug Program Counter Sample Register</i> on page H9-5637
EDPFR	<i>EDPFR, External Debug Processor Feature Register</i> on page H9-5641
EDPIDR0	<i>EDPIDR0, External Debug Peripheral Identification Register 0</i> on page H9-5644
EDPIDR1	<i>EDPIDR1, External Debug Peripheral Identification Register 1</i> on page H9-5645
EDPIDR2	<i>EDPIDR2, External Debug Peripheral Identification Register 2</i> on page H9-5646
EDPIDR3	<i>EDPIDR3, External Debug Peripheral Identification Register 3</i> on page H9-5647
EDPIDR4	<i>EDPIDR4, External Debug Peripheral Identification Register 4</i> on page H9-5648

**Table K11-28 Alphabetical index of Memory-Mapped Registers (continued)**

<b>Register</b>	<b>Description, see</b>
EDPRCR	<i>EDPRCR, External Debug Power/Reset Control Register on page H9-5649</i>
EDPRSR	<i>EDPRSR, External Debug Processor Status Register on page H9-5652</i>
EDRCR	<i>EDRCR, External Debug Reserve Control Register on page H9-5660</i>
EDSCR	<i>EDSCR, External Debug Status and Control Register on page H9-5662</i>
EDVIDSR	<i>EDVIDSR, External Debug Virtual Context Sample Register on page H9-5667</i>
EDWAR	<i>EDWAR, External Debug Watchpoint Address Register on page H9-5671</i>
MIDR_EL1	<i>MIDR_EL1, Main ID Register on page H9-5673</i>
OSLAR_EL1	<i>OSLAR_EL1, OS Lock Access Register on page H9-5675</i>
PMAUTHSTATUS	<i>PMAUTHSTATUS, Performance Monitors Authentication Status register on page I3-5750</i>
PMCCFILTR_EL0	<i>PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register on page I3-5752</i>
PMCCNTR_EL0	<i>PMCCNTR_EL0, Performance Monitors Cycle Counter on page I3-5754</i>
PMCEID0	<i>PMCEID0, Performance Monitors Common Event Identification register 0 on page I3-5756</i>
PMCEID1	<i>PMCEID1, Performance Monitors Common Event Identification register 1 on page I3-5758</i>
PMCEID2	<i>PMCEID2, Performance Monitors Common Event Identification register 2 on page I3-5760</i>
PMCEID3	<i>PMCEID3, Performance Monitors Common Event Identification register 3 on page I3-5762</i>
PMCFGR	<i>PMCFGR, Performance Monitors Configuration Register on page I3-5764</i>
PMCID1SR	<i>PMCID1SR, CONTEXTIDR_EL1 Sample Register on page I3-5770</i>
PMCID2SR	<i>PMCID2SR, CONTEXTIDR_EL2 Sample Register on page I3-5772</i>
PMCIDR0	<i>PMCIDR0, Performance Monitors Component Identification Register 0 on page I3-5766</i>
PMCIDR1	<i>PMCIDR1, Performance Monitors Component Identification Register 1 on page I3-5767</i>
PMCIDR2	<i>PMCIDR2, Performance Monitors Component Identification Register 2 on page I3-5768</i>
PMCIDR3	<i>PMCIDR3, Performance Monitors Component Identification Register 3 on page I3-5769</i>
PMCNTENCLR_EL0	<i>PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register on page I3-5774</i>
PMCNTENSET_EL0	<i>PMCNTENSET_EL0, Performance Monitors Count Enable Set register on page I3-5776</i>
PMCR_EL0	<i>PMCR_EL0, Performance Monitors Control Register on page I3-5778</i>
PMDEVAFF0	<i>PMDEVAFF0, Performance Monitors Device Affinity register 0 on page I3-5781</i>
PMDEVAFF1	<i>PMDEVAFF1, Performance Monitors Device Affinity register 1 on page I3-5782</i>
PMDEVARCH	<i>PMDEVARCH, Performance Monitors Device Architecture register on page I3-5783</i>
PMDEVID	<i>PMDEVID, Performance Monitors Device ID register on page I3-5785</i>
PMDEVTYPE	<i>PMDEVTYPE, Performance Monitors Device Type register on page I3-5786</i>
PMEVCNTR<n>_EL0	<i>PMEVCNTR&lt;n&gt;_EL0, Performance Monitors Event Count Registers, n = 0 - 30 on page I3-5787</i>
PMEVTYPEPER<n>_EL0	<i>PMEVTYPEPER&lt;n&gt;_EL0, Performance Monitors Event Type Registers, n = 0 - 30 on page I3-5788</i>

**Table K11-28 Alphabetical index of Memory-Mapped Registers (continued)**

<b>Register</b>	<b>Description, see</b>
PMINTENCLR_EL1	<i>PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register on page I3-5791</i>
PMINTENSET_EL1	<i>PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register on page I3-5793</i>
PMITCTRL	<i>PMITCTRL, Performance Monitors Integration mode Control register on page I3-5795</i>
PMLAR	<i>PMLAR, Performance Monitors Lock Access Register on page I3-5797</i>
PMLSR	<i>PMLSR, Performance Monitors Lock Status Register on page I3-5798</i>
PMOVSCLR_EL0	<i>PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register on page I3-5800</i>
PMOVSSET_EL0	<i>PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register on page I3-5802</i>
PMPCSR	<i>PMPCSR, Program Counter Sample Register on page I3-5804</i>
PMPIDR0	<i>PMPIDR0, Performance Monitors Peripheral Identification Register 0 on page I3-5806</i>
PMPIDR1	<i>PMPIDR1, Performance Monitors Peripheral Identification Register 1 on page I3-5807</i>
PMPIDR2	<i>PMPIDR2, Performance Monitors Peripheral Identification Register 2 on page I3-5808</i>
PMPIDR3	<i>PMPIDR3, Performance Monitors Peripheral Identification Register 3 on page I3-5809</i>
PMPIDR4	<i>PMPIDR4, Performance Monitors Peripheral Identification Register 4 on page I3-5810</i>
PMSWINC_EL0	<i>PMSWINC_EL0, Performance Monitors Software Increment register on page I3-5811</i>
PMVIDSR	<i>PMVIDSR, VMID Sample Register on page I3-5813</i>

## K11.7 Functional index of memory-mapped registers

This section is an index of the memory-mapped registers, divided by functional group.

### K11.7.1 ID registers

This section is an index to the registers in the Identification registers functional group.

**Table K11-29 ID registers**

Register	Description, see
EDAA32PFR	<a href="#">EDAA32PFR</a>
EDDFR	<a href="#">EDDFR</a>
EDPFR	<a href="#">EDPFR</a>
MIDR_EL1	<a href="#">MIDR_EL1</a>

### K11.7.2 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

**Table K11-30 Performance monitors registers**

Register	Description, see
PMAUTHSTATUS	<a href="#">PMAUTHSTATUS</a>
PMCCFILTR_EL0	<a href="#">PMCCFILTR_EL0</a>
PMCCNTR_EL0	<a href="#">PMCCNTR_EL0</a>
PMCEID0	<a href="#">PMCEID0</a>
PMCEID1	<a href="#">PMCEID1</a>
PMCEID2	<a href="#">PMCEID2</a>
PMCEID3	<a href="#">PMCEID3</a>
PMCFGR	<a href="#">PMCFGR</a>
PMCID1SR	<a href="#">PMCID1SR</a>
PMCID2SR	<a href="#">PMCID2SR</a>
PMCIDR0	<a href="#">PMCIDR0</a>
PMCIDR1	<a href="#">PMCIDR1</a>
PMCIDR2	<a href="#">PMCIDR2</a>
PMCIDR3	<a href="#">PMCIDR3</a>
PMCNTENCLR_EL0	<a href="#">PMCNTENCLR_EL0</a>
PMCNTENSET_EL0	<a href="#">PMCNTENSET_EL0</a>
PMCR_EL0	<a href="#">PMCR_EL0</a>
PMDEVAFF0	<a href="#">PMDEVAFF0</a>

**Table K11-30 Performance monitors registers (continued)**

Register	Description, see

CTITRIGOUTSTATUS	<a href="#">CTITRIGOUTSTATUS</a>

# Glossary

<b>A32 instruction</b>	<p>A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.</p> <p>A32 instructions were previously called ARM instructions.</p> <p><i>See also</i> <a href="#">A32 state</a>, <a href="#">A64 instruction</a>, <a href="#">T32 instruction</a>.</p>
<b>A32 state</b>	<p>The AArch32 Instruction set state in which the PE executes A32 instructions.</p> <p>A32 state was previously called ARM state.</p> <p><i>See also</i> <a href="#">T32 instruction</a>, <a href="#">T32 state</a>.</p>
<b>A64 instruction</b>	<p>A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.</p> <p><i>See also</i> <a href="#">A32 instruction</a>, <a href="#">T32 instruction</a>.</p>
<b>AArch32</b>	<p>The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets</p> <p><i>See also</i> <a href="#">AArch64</a>, <a href="#">A32 instruction</a>, <a href="#">T32 instruction</a>.</p>
<b>AArch64</b>	<p>The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.</p> <p><i>See also</i> <a href="#">AArch32</a>, <a href="#">A64 instruction</a>.</p>
<b>Abort</b>	<p>An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.</p>
<b>Addressing mode</b>	<p>Means a method for generating the memory address used by a load/store instruction.</p>
<b>Advanced SIMD</b>	<p>A feature of the ARM architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.</p>

<b>Aligned</b>	<p>A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.</p> <p>An aligned access is one where the address of the access is aligned to the size of each element of the access.</p>
<b>Architecturally executed</b>	<p>An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been <i>architecturally executed</i>. Any instruction that, in a simple sequential execution of a program, is treated as a NOP because it fails its condition code check, is an architecturally executed instruction.</p> <p>In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.</p> <p>See also <a href="#">Condition code check</a>, <a href="#">Simple sequential execution</a>.</p>
<b>Architecturally mapped</b>	<p>Where this manual describes a register as being <i>architecturally mapped</i> to another register, this indicates that, in an implementation that supports both of the registers, the two registers access the same state.</p>
<b>Architecturally UNKNOWN</b>	<p>An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of <a href="#">UNKNOWN</a>. Implementations can define the value of the field, but are not required to do so.</p> <p>See also <a href="#">IMPLEMENTATION DEFINED</a>.</p>
<b>ARM core registers</b>	<p>Some older documentation uses <i>ARM core registers</i> to refer to the following set of registers for execution in AArch32 state:</p> <ul style="list-style-type: none"> <li>• The 13 general-purpose registers, R0-R12, that software can use for processing.</li> <li>• SP, the <i>stack pointer</i>, that can also be referred to as R13.</li> <li>• LR, the <i>link register</i>, that can also be referred to as R14.</li> <li>• PC, the <i>program counter</i>, that can also be referred to as R15.</li> </ul> <p>See also <a href="#">General-purpose registers</a>.</p>
<b>ARM instruction</b>	<p>See <a href="#">A32 instruction</a>.</p>
<b>Associativity</b>	<p>See <a href="#">Cache associativity</a>.</p>
<b>Atomicity</b>	<p>Describes either single-copy atomicity or multi-copy atomicity. <a href="#">Atomicity in the ARM architecture on page B2-82</a> defines these forms of atomicity for the ARM architecture.</p> <p>See also <a href="#">Multi-copy atomicity</a>, <a href="#">Single-copy atomicity</a>.</p>
<b>Banked register</b>	<p>A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.</p>
<b>Base register</b>	<p>A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.</p>
<b>Base register writeback</b>	<p>Describes writing back a modified value to the base register used in an address calculation.</p>
<b>Behaves as if</b>	<p>Where this manual indicates that a PE <i>behaves as if</i> a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.</p>

**Big-endian memory**

Means that, for example:

- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.

See also [Endianness](#), [Little-endian memory](#).

**Blocking**

Describes an operation that does not permit following instructions to be executed before the operation completes.

A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

**Branch prediction**

Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.

See also [Prefetching](#).

**Breakpoint**

A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

**Byte**

An 8-bit data item.

**Cache associativity**

The number of locations in a cache set to which an address can be assigned. Each location is identified by its *way* value.

**Cache level**

The position of a cache in the cache hierarchy. In the ARM architecture, the lower numbered levels are those closest to the PE. For more information, see [Terms used in describing the cache maintenance instructions on page D3-1981](#).

**Cache line**

The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A *memory cache line* is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

**Cache lockdown**

Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

**Cache miss**

A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

**Cache sets**

Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

**Cache way**

A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way *n* consists of the cache line with index *n* from each cache set.

**Coherence order**

See [Coherent](#).

**Coherent**

Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all writes to that memory location is the *coherence order* for that byte in memory.

**Condition code check**

The process of determining whether a conditional instruction executes normally or is treated as a NOP. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of [PSTATE.IT](#) determines whether the instruction is executed normally.

See also [Condition code field](#), [Condition flags](#), [Conditional execution](#).

**Condition code field**

A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also [Condition code check](#).

**Condition flags**

The N, Z, C, and V bits of PSTATE, an SPSR, or FPSCR. See the register descriptions for more information.

See also [Condition code check](#), [PSTATE](#).

**Conditional execution**

When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a NOP.

See also [Condition code check](#).

**CONSTRAINED UNPREDICTABLE**

Where an instruction can result in UNPREDICTABLE behavior, the ARMv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Execution at Non-secure EL1 or EL0 of an instruction that is CONSTRAINED UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term CONSTRAINED UNPREDICTABLE is shown in SMALL CAPITALS.

See also [UNPREDICTABLE](#).

**Context switch**

The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

**Context synchronization event**

One of:

- Performing an ISB operation. An ISB operation is performed when an ISB instruction is executed and does not fail its condition code check.
- Taking an exception.
- Returning from an exception.
- Exit from Debug state.
- Executing a DCP5 instruction.
- Executing a DRPS instruction.

The effects of a Context synchronization event are:

- All unmasked interrupts that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- If halting is allowed, all Halting debug events that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- No instructions appearing in program order after an instruction that causes a Context synchronization event will have performed any part of their functionality until the Context synchronization event has occurred.
- All direct and indirect writes to System registers that are made before the Context synchronization event affect any instruction, including a direct read, that appears in program order after the instruction causing the Context synchronization event.
- All invalidations of TLBs, instruction caches, and, in AArch32 state, branch predictors, that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.
- In AArch32 state, all Non-cacheable writes that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.

- Changes to the Debug external authentication interfaces that are made before the Context synchronization event affect any instruction that appears in program order after the instruction causing the Context synchronization event.

---

**Note**

---

The architecture requires that instructions that generate Context synchronization events do not appear to be executed speculatively, except that it is permissible that the performance counters can reveal such speculation.

---

---

**Note**

---

*Context synchronization events* were previously described as *context synchronization operations*.

---

**Debugger**

In most of this manual, *debugger* refers to any agent that is performing debug. However, some chapters or parts of this manual require a more rigorous definition, and define debugger locally. See:

- [Definition of a debugger in the context of self-hosted debug on page D2-1906](#).
- [Definition of a debugger in the context of self-hosted debug on page G2-4454](#).
- [Definition of a debugger in the context of external debug on page H1-5430](#).

**Deprecated**

Something that is present in the ARM architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the ARM architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the ARM architecture.

See also [OPTIONAL](#).

**Digital signal processing (DSP)**

Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

**Direct Memory Access (DMA)**

An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.

**Direct read**

A direct read of a System register is a read performed by a System register access instruction.

For more information, see [Direct read on page D7-2193](#).

See also [Direct write](#), [Indirect read](#), [Indirect write](#).

**Direct write**

A direct write of a System register is a write performed by a System register access instruction.

For more information, see [Direct write on page D7-2193](#).

See also [Direct read](#), [Indirect read](#), [Indirect write](#).

**DMA**

See [Direct Memory Access \(DMA\)](#).

**DNM**

See [Do-Not-Modify \(DNM\)](#).

**Domain**

In the ARM architecture, *domain* is used in the following contexts.

**Shareability domain** Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.

**Power domain** Defines a block of logic with a single, common, power supply.

**Memory regions domain**

When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the *Domain Access Control Register (DACR)*. ARM deprecates any use of memory regions domains.

**Do-Not-Modify (DNM)**

Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

**Double-precision value**

Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

**Doubleword**

A 64-bit data item. Doublewords are normally at least word-aligned in ARM systems.

**Doubleword-aligned**

Means that the address is divisible by 8.

**DSP**

See [Digital signal processing \(DSP\)](#).

**Effective value**

A register control field, meaning a field in a register that controls some aspect of the behavior, can be described as having an Effective value:

- In some cases, the description of a control *a* specifies that when control *a* is active it causes a register control field *b* to be treated as having a fixed value for all purposes other than direct reads, or direct reads and direct writes, of the register containing control field *b*. When control *a* is active that fixed value is described as the *Effective value* of register control field *b*. For example, when the value of HCR.DC is 1, the *Effective value* of HCR.VM is 1, regardless of its actual value.

In other cases, in some contexts a register control field *b* is not implemented or is not accessible, but behavior of the PE is as if control field *b* was implemented and accessible, and had a particular value. In this case, that value is the *Effective value* of register control field *b*.

———— **Note** ————

Where a register control field is introduced in a particular version of the architecture, and is not implemented in an earlier version of the architecture, typically it will have an Effective value in that earlier version of the architecture.

- Otherwise, the *Effective value* of a register control field is the value of that field.

**Endianness**

An aspect of the system memory mapping.

See also [Big-endian memory](#) and [Little-endian memory](#).

**Exception**

Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

**Exception vector**

A fixed address that contains the address of the first instruction of the corresponding exception handler.

**Execution stream**

The stream of instructions that would have been executed by sequential execution of the program.

**Explicit access**

A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses are not explicit accesses.

**External abort**

An abort that is generated by the external memory system.

**Fast Context Switch Extension (FCSE)**

Modifies the behavior of an ARM memory system to enable multiple programs running on the ARM PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. From ARMv6, ARM deprecates any use of the FCSE. The FCSE is:

- Optional in an ARMv7 implementation that does not include the Multiprocessing Extensions.
- Obsolete from the introduction of the Multiprocessing Extensions.

**FCSE**

See [Fast Context Switch Extension \(FCSE\)](#).

**Flat address mapping**

Is where the physical address for every access is equal to its virtual address.

**Flush-to-zero mode**

A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.

**General-purpose registers**

The registers that the base instructions use for processing:

- In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.

———— **Note** ————

Older documentation defines the AArch32 general-purpose registers as R0-R12, and the ARM core registers as R0-R12, SP, LR, and PC.

- In AArch64 state the general-purpose registers are:
  - W0-W30 when accessed as 32-bit registers.
  - X0-X30 when accessed as 64-bit registers.

See also [High registers](#), [Low registers](#).

**Halfword**

A 16-bit data item. Halfwords are normally halfword-aligned in ARM systems.

**Halfword-aligned**

Means that the address is divisible by 2.

**High registers**

In AArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

———— **Note** ————

In some contexts, *high registers* refers to R8-R15, meaning R8-R14 and the PC.

See also [General-purpose registers](#), [Low registers](#).

**High vectors**

An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

**IGNORED**

Indicates that the architecture guarantees that the bit or field is not interpreted or modified by hardware.

In body text, the term IGNORED is shown in SMALL CAPITALS.

**Immediate and offset fields**

Are unsigned unless otherwise stated.

**Immediate value**

A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.

**IMP**

An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

**IMPLEMENTATION DEFINED**

Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

**Index register**

A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

**Indirect read**

When an instruction uses a System register value to establish operating conditions, that use of the System register is an indirect read of the System register.

For more information, including additional examples of indirect reads, see [Indirect read on page D7-2194](#).

See also [Direct read](#), [Direct write](#), [Indirect write](#).

<b>Indirect write</b>	<p>An indirect write of a System register occurs when the contents of a register are updated by some mechanism other than a <i>Direct write</i> to that register. For example, an indirect write to a register might occur as a side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation performed by an external agent.</p> <p>For more information, see <a href="#">Indirect write on page D7-2194</a>.</p> <p>See also <a href="#">Direct read</a>, <a href="#">Direct write</a>, <a href="#">Indirect read</a>.</p>
<b>Inline literals</b>	<p>These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.</p>
<b>Intermediate physical address (IPA)</b>	<p>An implementation of virtualization, the address to which a Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.</p> <p>See also <a href="#">Physical address (PA)</a>, <a href="#">Virtual address (VA)</a>.</p>
<b>Interworking</b>	<p>A method of working that permits branches between software using the A32 and T32 instruction sets.</p>
<b>IPA</b>	<p>See <a href="#">Intermediate physical address (IPA)</a>.</p>
<b>Level</b>	<p>See <a href="#">Cache level</a>.</p>
<b>Level of Coherence (LoC)</b>	<p>The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information, see <a href="#">Terms used in describing the cache maintenance instructions on page D3-1981</a>.</p> <p>See also <a href="#">Cache level</a>, <a href="#">Point of coherency (PoC)</a>.</p>
<b>Level of Unification, Inner Shareable (LoUIS)</b>	<p>The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information, see <a href="#">Terms used in describing the cache maintenance instructions on page D3-1981</a>.</p> <p>See also <a href="#">Cache level</a>, <a href="#">Point of unification (PoU)</a>.</p>
<b>Level of Unification, uniprocessor (LoUU)</b>	<p>For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information, see <a href="#">Terms used in describing the cache maintenance instructions on page D3-1981</a>.</p> <p>See also <a href="#">Cache level</a>, <a href="#">Point of unification (PoU)</a>.</p>
<b>Line</b>	<p>See <a href="#">Cache line</a>.</p>
<b>Little-endian memory</b>	<p>Means that, for example:</p> <ul style="list-style-type: none"> <li>• A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.</li> <li>• A byte at a halfword-aligned address is the least significant byte in the halfword at that address.</li> </ul> <p>See also <a href="#">Big-endian memory</a>, <a href="#">Endianness</a>.</p>
<b>Load/Store architecture</b>	<p>An architecture where data-processing operations only operate on register contents, not directly on memory contents.</p>
<b>LoC</b>	<p>See <a href="#">Level of Coherence (LoC)</a>.</p>
<b>LoUIS</b>	<p>See <a href="#">Level of Unification, Inner Shareable (LoUIS)</a>.</p>
<b>LoUU</b>	<p>See <a href="#">Level of Unification, uniprocessor (LoUU)</a>.</p>
<b>Lockdown</b>	<p>See <a href="#">Cache lockdown</a>.</p>

<b>Low registers</b>	In AArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.  <i>See also</i> <a href="#">General-purpose registers</a> , <a href="#">High registers</a> .
<b>Memory barrier</b>	<i>See</i> <a href="#">Memory barriers on page B2-92</a> .
<b>Memory coherency</b>	The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.
<b>Memory Management Unit (MMU)</b>	Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.
<b>Memory Protection Unit (MPU)</b>	A hardware unit whose registers provide simple control of a limited number of protection regions in memory.
<b>Miss</b>	<i>See</i> <a href="#">Cache miss</a> .
<b>MMU</b>	<i>See</i> <a href="#">Memory Management Unit (MMU)</a> .
<b>MPU</b>	<i>See</i> <a href="#">Memory Protection Unit (MPU)</a> .
<b>Multi-copy atomicity</b>	The form of atomicity described in <a href="#">Requirements for multi-copy atomicity on page B2-83</a> .  <i>See also</i> <a href="#">Atomicity</a> , <a href="#">Single-copy atomicity</a> .
<b>NaN</b>	Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a <i>quiet</i> NaN, that propagate through most floating-point operations, or a <i>signaling</i> NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the <i>IEEE Standard for Floating-point Arithmetic</i> .  <i>See also</i> <a href="#">Quiet NaN</a> , <a href="#">Signaling NaN</a> .
<b>Natural eviction</b>	A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as the execution of a cache maintenance instruction. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.
<b>Observer</b>	A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.
<b>Obsolete</b>	Obsolete indicates something that is no longer supported by ARM. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.
<b>Offset addressing</b>	Means that the memory address is formed by adding or subtracting an offset to or from the base register value.
<b>OPTIONAL</b>	When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the ARM architecture: <ul style="list-style-type: none"> <li>If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. ARM expects such a features to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature. A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.</li> <li>A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the ARM architecture after the initial release of that version of the architecture. ARM recommends that such features are included in all new implementations of the architecture.</li> </ul> <p>In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.</p>

---

**Note**

---

Do not confuse these ARM-specific uses of **OPTIONAL** with other uses of *optional*, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
  - Behavior determined by an implementation choice, for example the optional byte order reversal in an ARMv7-R implementation, where the [SCTLR.IE](#) bit indicates the implemented option.
- 

See also [Deprecated](#).

**PA** See [Physical address \(PA\)](#).

**PE** See [Processing element \(PE\)](#).

**Physical address (PA)**

An address that identifies a location in the physical memory map.

See also [Intermediate physical address \(IPA\)](#), [Virtual address \(VA\)](#).

**PoC** See [Point of coherency \(PoC\)](#).

**PoU** See [Point of unification \(PoU\)](#).

**Point of coherency (PoC)**

For a particular VA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information, see [Terms used in describing the cache maintenance instructions on page D3-1981](#).

**Point of unification (PoU)**

For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information, see [Terms used in describing the cache maintenance instructions on page D3-1981](#).

**Post-indexed addressing**

Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

**Prefetching**

Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

---

**Note**

---

The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

---

See also [Simple sequential execution](#).

**Pre-indexed addressing**

Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

**Processing element (PE)**

The abstract machine defined in the ARM architecture, as documented in an ARM Architecture Reference Manual. A PE implementation compliant with the ARM architecture must conform with the behaviors described in the corresponding ARM Architecture Reference Manual.

**Protection region**

A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

**Protection Unit**    *See* [Memory Protection Unit \(MPU\)](#).

**Pseudo-instruction**

UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV <Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL <Rd>, <Rm>, #<n>`.

**PSTATE**    An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

*See also* [Condition flags](#).

**Quadword**    A 128-bit data item. Quadwords are normally at least word-aligned in ARM systems.

**Quadword-aligned**

Means that the address is divisible by 16.

**Quiet NaN**    A NaN that propagates unchanged through most floating-point operations.

*See also* [NaN](#), [Signaling NaN](#).

**RAO**    *See* [Read-As-One \(RAO\)](#).

**RAZ**    *See* [Read-As-Zero \(RAZ\)](#).

**RAO/SBOP**    In versions of the ARM architecture before ARMv8, Read-As-One, Should-Be-One-or-Preserved on writes. In ARMv8, RES1 replaces this description.

*See also* [UNK/SBOP](#), [Read-As-One \(RAO\)](#), [RES1](#), [Should-Be-One-or-Preserved \(SBOP\)](#).

**RAO/WI**    Read-As-One, Writes Ignored.

Hardware must implement the field as Read-as-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

*See also* [Read-As-One \(RAO\)](#).

**RAZ/SBZP**    In versions of the ARM architecture before ARMv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes. In ARMv8, RES0 replaces this description.

*See also* [UNK/SBZP](#), [Read-As-Zero \(RAZ\)](#), [RES0](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#).

**RAZ/WI**    Read-As-Zero, Writes Ignored.

Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.

Software can rely on the field reading as all 0s, and on writes being ignored.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

*See also* [Read-As-Zero \(RAZ\)](#).

**Read-allocate cache**

A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

**Read-As-One (RAO)**

Hardware must implement the field as reading as all 1s.

Software:

- Can rely on the field reading as all 1s.
- Must use a [SBOP](#) policy to write to the field.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

*See also* [RAO/SBOP](#), [RAO/WI](#), [RES1](#).

**Read-As-Zero (RAZ)**

Hardware must implement the field as reading as all 0s.

Software:

- Can rely on the field reading as all 0s
- Must use a [SBZP](#) policy to write to the field.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also [RAZ/SBZP](#), [RAZ/WI](#), [RES0](#).

**Read, modify, write**

In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

**RES0**

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES0 in some defined architectural context.
- Has different defined behavior in a different architectural context.

---

**Note**

---

- RES0 is not used in descriptions of instruction encodings.
  - Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES0 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.
- 

This means the definition of RES0 for fields in read/write registers is:

**If a bit is RES0 in all contexts**

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 0. In this case:
  - Reads of the bit always return 0.
  - Writes to the bit are ignored.
2. The bit can be written. In this case:
  - An indirect write to the register sets the bit to 0.
  - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.  
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
  - A direct write to the bit must update a storage location associated with the bit.
  - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

**If a bit is RES0 only in some contexts**

For a bit in a read/write register, when the bit is described as RES0:

- An indirect write to the register sets the bit to 0.
- A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.  
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as [SBZ](#).

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 0.
- Must use an [SBZP](#) policy to write to the bit.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.

In body text, the term RES0 is shown in SMALL CAPITALS.

See also [Read-As-Zero \(RAZ\)](#), [RES1](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), [UNKNOWN](#).

## RES1

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

### ———— Note ————

- RES1 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES1 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES1 for fields in read/write registers is:

### If a bit is RES1 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
  - Reads of the bit always return 1.
  - Writes to the bit are ignored.
2. The bit can be written. In this case:
  - An indirect write to the register sets the bit to 1.
  - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.  
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
  - A direct write to the bit must update a storage location associated with the bit.
  - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

#### If a bit is RES1 only in some contexts

For a bit in a read/write register, when the bit is described as RES1:

- An indirect write to the register sets the bit to 1.
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

#### Note

As indicated in this list, this value might be written by an indirect write to the register.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES1 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as SBO.

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 1.
- Must use an SBOP policy to write to the bit.

This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALL CAPITALS.

See also [Read-As-One \(RAO\)](#), [RES0](#), [Should-Be-One-or-Preserved \(SBOP\)](#), [UNKNOWN](#).

## Reserved

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- Bit positions described as reserved are:
  - In an RW or WO register, RES0.
  - In an RO register, UNK.

See also [CONSTRAINED UNPREDICTABLE](#), [RES0](#), [RES1](#), [UNDEFINED](#), [UNK](#), [UNPREDICTABLE](#).

## RISC

Reduced Instruction Set Computer.

## Rounding error

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

## Rounding mode

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the *IEEE Standard for Floating-point Arithmetic*, see [Floating-point standards, and terminology on page A1-49](#).

**Saturated arithmetic**

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in ARM processors, in which overflowing results wrap around from  $+2^{31}-1$  to  $-2^{31}$  or vice versa.

**SBO**

See [Should-Be-One \(SBO\)](#).

**SBOP**

See [Should-Be-One-or-Preserved \(SBOP\)](#).

**SBZ**

See [Should-Be-Zero \(SBZ\)](#).

**SBZP**

See [Should-Be-Zero-or-Preserved \(SBZP\)](#).

**Security hole**

A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The ARM architecture forbids security holes.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

**Self-modifying code**

Code that writes one or more instructions to memory and then executes them. When using self-modifying code, you must use cache maintenance and barrier instructions to ensure synchronization. For more information, see [Caches and memory hierarchy on page B2-97](#).

**Set**

See [Cache sets](#).

**Should-Be-One (SBO)**

Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

**Should-Be-One-or-Preserved (SBOP)**

From the introduction of the ARMv8 architecture, the description *Should-Be-One-or-Preserved (SBOP)* is superseded by [RESI](#).

---

**Note**

---

The ARMv7 Large Physical Address Extension modified the definition of SBOP for register bits that are SBOP in some but not all contexts. The behavior of these bits is covered by the [RESI](#) definition, but not by the generic definition of SBOP given here.

---

Hardware must ignore writes to the field.

When writing this field, software must either write all 1s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is UNPREDICTABLE.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

**Should-Be-Zero (SBZ)**

Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

**Should-Be-Zero-or-Preserved (SBZP)**

From the introduction of the ARMv8 architecture, the description *Should-Be-Zero-or-Preserved (SBZP)* is superseded by [RES0](#).

---

**Note**

---

The ARMv7 Large Physical Address Extension modified the definition of SBZP for register bits that are SBZP in some but not all contexts. The behavior of these bits is covered by the [RES0](#) definition, but not by the generic definition of SBZP given here.

---

Hardware must ignore writes to the field.

When writing this field, software must either write all 0s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is UNPREDICTABLE.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

**Signaling NaN**

An Invalid Operation floating-point exception occurs whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

See also [NaN](#), [Quiet NaN](#).

**Signed immediate and offset fields**

Are encoded in two's complement notation unless otherwise stated.

**SIMD**

Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in [Parallel addition and subtraction instructions on page F1-2818](#).
- The Advanced SIMD instructions summarized in [Advanced SIMD and floating-point instructions on page E1-2740](#), when operating on vectors.

---

**Note**

---

In ARMv7, some VFP instructions can operate on vectors. However, ARM deprecates those instruction uses, and strongly recommends that Advanced SIMD instructions are always used for vector operations.

---

**Simple sequential execution**

The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and ARM does not expect this model to correspond to a realistic implementation of the architecture.

**Single-copy atomicity**

The form of atomicity described in [Properties of single-copy atomic accesses on page B2-83](#).

See also [Atomicity](#), [Multi-copy atomicity](#).

**Single-precision value**

A 32-bit word that is interpreted as a basic single-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

**Spatial locality**

The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

**Speculative**

Speculative operations are:

- Operations that are generated by instructions that appear in the Execution stream after a branch that is not architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.
- Operations that are generated by conditional instructions for which the conditions for the instruction have not been architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after the point at which a precise asynchronous exception will be taken.
- Reads or writes generated by load or store instructions for which the data being written or the address being accessed comes from a register that has not been architecturally resolved.
- Operations generated by the hardware that are not directly generated by any instructions appearing in the Execution stream.

See also [Execution stream](#).

**Special-purpose register**

One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization:

- [Special-purpose registers on page C5-336](#) specifies the AArch64 Special-purpose registers.
- [AArch32 Special-purpose registers on page G1-4328](#) lists the AArch32 Special-purpose registers.

**T32 instruction**

One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 instructions were previously called Thumb instructions.

See also [A32 instruction](#), [A64 instruction](#), [T32 state](#).

**T32 state**

The AArch32 Instruction set state in which the PE executes T32 instructions.

T32 state was previously called Thumb state.

See also [A32 state](#), [T32 instruction](#).

**Taken locally**

An exception that is taken locally means an exception that is taken to the default Exception level, and is not routed to another Exception level.

**Temporal locality**

The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

**Thumb instruction**

See [T32 instruction](#).

**TLB**

See [Translation Lookaside Buffer \(TLB\)](#).

**TLB lockdown**

A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.

**Translation Lookaside Buffer (TLB)**

A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the ARM implementation.

**Translation table**

A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

**Translation table walk**

The process of doing a full translation table lookup. It is performed automatically by hardware.

**Trap enable bits**

In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

**Unaligned**

An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

**Unaligned memory accesses**

Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

**Unallocated**

Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#), [UNPREDICTABLE](#).

**UNDEFINED**

Indicates cases where an attempt to execute a particular encoding bit pattern generates an exception, that is taken to the current Exception level, or to the default Exception level for taking exceptions if the UNDEFINED encoding was executed at EL0. This applies to:

- Any encoding that is not allocated to any instruction.
- Any encoding that is defined as never accessible at the current Exception level.
- Some cases where an enable, disable, or trap control means an encoding is not accessible at the current Exception level.

If the generated exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.

———— **Note** ————

On reset, the default Exception level for taking exceptions from EL0 is EL1. However, an implementation might include controls that can change this, effectively making EL1 inactive. See the description of the Exception model for more information

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also [Undefined Instruction exception on page G1-4376](#).

**Unified cache**

Is a cache used for both processing instruction fetches and processing data loads and stores.

**Unindexed addressing**

Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

In ARMv7 and earlier versions of the ARM architecture, and in the M-profile, the LDC, LDC2, STC, and STC2 instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

**UNK**

An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also [UNKNOWN](#).

**UNK/SBOP**

Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

*See also* [Read-As-One \(RAO\)](#), [Should-Be-One-or-Preserved \(SBOP\)](#), [UNKNOWN](#).

## UNK/SBZP

Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

*See also* [Read-As-Zero \(RAZ\)](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), [UNKNOWN](#).

## UNKNOWN

An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

*See also* [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#), [UNK](#), [UNPREDICTABLE](#).

## UNPREDICTABLE

Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Execution at Non-secure EL1 or EL0 of an instruction that is UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

*See also* [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#).

## VA

*See* [Virtual address \(VA\)](#).

## VFP

In ARMv7, an extension to the ARM architecture, that provides single-precision and double-precision floating-point arithmetic.

## Virtual address (VA)

An address generated by an ARM PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.

*See also* [Intermediate physical address \(IPA\)](#), [Physical address \(PA\)](#).

## Watchpoint

A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

## Way

*See* [Cache way](#).

## WI

Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

*See also* [RAO/WI](#), [RAZ/WI](#), [RES0](#), [RES1](#).

## Word

A 32-bit data item. Words are normally word-aligned in ARM systems.

## Word-aligned

Means that the address is divisible by 4.

**Write-allocate cache**

A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

**Write-back cache**

A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a *copy-back cache*.

**Write-through cache**

A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

**Write buffer**

A block of high-speed memory that optimizes stores to main memory.
