STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #<+/->imm

### Pre-indexed variant

Applies when  $P == 1$  &  $W == 1$ .

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #<+/->imm]!

### Decode for all variants of this encoding

```
if P == '0' & W == '0' then SEE "Related encodings";
t = UInt(Rt); t2 = UInt(Rt2); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if wback & (n == t || n == t2) then UNPREDICTABLE;
if n == 15 || t == 15 || t2 == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### CONSTRAINED UNPREDICTABLE behavior

If  $t == 15$  ||  $t2 == 15$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Load/store dual, load/store exclusive, load-acquire/store-release, and table branch](#) on page F3-2913.

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<Rt>	For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14. For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.
<Rt2>	For encoding A1: is the second general-purpose register to be transferred. This register must be <R(t+1)>. For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Rn>	For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For encoding T1: is the general-purpose base register, encoded in the "Rn" field.
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: -           when U = 0 +           when U = 1
<imm>	For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For encoding T1: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 if omitted, and encoded in the "imm8" field as <imm>/4.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        bits(64) data;

```

```
if BigEndian() then
    data<63:32> = R[t];
    data<31:0> = R[t2];
else
    data<31:0> = R[t];
    data<63:32> = R[t2];
MemA[address,8] = data;
else
    MemA[address,4] = R[t];
    MemA[address+4,4] = R[t2];
if wback then R[n] = offset_addr;
```

## F5.1.229 STRD (register)

Store Register Dual (register) calculates an address from a base register value and a register offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#) on page F2-2854.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
!=1111	0	0	0	P	U	0	W	0	Rn	Rt	(0)	(0)	(0)	(0)	1	1	1	1	Rm				
cond																							

#### Offset variant

Applies when P == 1 && W == 0.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]

#### Post-indexed variant

Applies when P == 0 && W == 0.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], {+/-}<Rm>

#### Pre-indexed variant

Applies when P == 1 && W == 1.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]!

#### Decode for all variants of this encoding

```

if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt); t2 = t+1; n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if t2 == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;

```

#### CONSTRAINED UNPREDICTABLE behavior

If t == 15 || t2 == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If  $Rt<0> == '1'$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode:  $t<0> = '0'$ .
- The instruction executes with the additional decode:  $t2 = t$ .
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when  $Rt == '1111'$ .

If  $P == '0'$  &&  $W == '1'$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode:  $P = '1'$ ;  $W = '0'$ .
- The instruction executes with the additional decode:  $P = '1'$ ;  $W = '1'$ .
- The instruction executes with the additional decode:  $P = '0'$ ;  $W = '0'$ .

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rt>	Is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.
<Rt2>	Is the second general-purpose register to be transferred. This register must be <R(t+1)>.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.
+/-	Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when <math>U = 0</math></li> <li>+ when <math>U = 1</math></li> </ul>
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        bits(64) data;
        if BigEndian() then
            data<63:32> = R[t];
            data<31:0> = R[t2];

```

```
    else
        data<31:0> = R[t];
        data<63:32> = R[t2];
        MemA[address,8] = data;
    else
        MemA[address,4] = R[t];
        MemA[address+4,4] = R[t2];
    if wback then R[n] = offset_addr;
```

## F5.1.230 STREX

Store Register Exclusive calculates an address from a base register value and an immediate offset, stores a word from a register to the calculated address if the PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores on page E2-2795](#). For information about memory accesses see [Memory accesses on page F2-2854](#).

### A1

cond																							

### A1 variant

STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, {#}<imm>}]

### Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); n = UInt(Rn); imm32 = Zeros(32); // Zero offset
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If d == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If d == n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	8	7				0
1	1	1	0	1	0	0	0	0	0	1	0	0	Rn	Rt	Rd							imm8

### T1 variant

STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, #<imm>}]

### Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
```

### **CONSTRAINED UNPREDICTABLE behavior**

If  $d == t$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If  $d == n$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

### **Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### **Assembler symbols**

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<imm>	For encoding A1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted. For encoding T1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

### **Aborts and alignment**

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemA[address,4] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## F5.1.231 STREXB

Store Register Exclusive Byte derives an address from a base register value, stores a byte from a register to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores on page E2-2795](#). For information about memory accesses see [Memory accesses on page F2-2854](#).

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0

### A1 variant

STREXD{<C>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

### Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); t2 = t+1; n = UInt(Rn);
if d == 15 || Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If d == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If d == n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

If Rt<0> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: Rt<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If Rt == '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in [Using R15 on page K1-6097](#).

## T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	8	7	6	5	4	3	0

if d == 15 || t == 15 || t2 == 15 || n == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If  $d == t$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If  $d == n$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<C>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory. <Rd> must not be the same as <Rn>, <Rt>, or <Rt2>.
<Rt>	For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. <Rt> must be even-numbered and not R14. For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.
<Rt2>	For encoding A1: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>. For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

### Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non doubleword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
    if AArch32.ExclusiveMonitorsPass(address,8) then
        MemA[address,8] = value; R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## F5.1.233 STREXH

Store Register Exclusive Halfword derives an address from a base register value, stores a halfword from a register to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores on page E2-2795](#). For information about memory accesses see [Memory accesses on page F2-2854](#).

### Assembler symbols

<C>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .				
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .				
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: <table> <tr> <td>0</td><td>If the operation updates memory.</td></tr> <tr> <td>1</td><td>If the operation fails to update memory.</td></tr> </table>	0	If the operation updates memory.	1	If the operation fails to update memory.
0	If the operation updates memory.				
1	If the operation fails to update memory.				
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.				
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.				

### Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,2) then
        MemA[address,2] = R[t]<15:0>;
```

```
        R[d] = ZeroExtend('0');  
else  
        R[d] = ZeroExtend('1');
```

## F5.1.234 STRH (immediate)

Store Register Halfword (immediate) calculates an address from a base register value and an immediate offset, and stores a halfword from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2854](#).

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
!=1111	0	0	0	P	U	1	W	0	Rn	Rt	imm4H	1	0	1	1	imm4L					
cond																					

#### Offset variant

Applies when P == 1 && W == 0.

STRH{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

#### Post-indexed variant

Applies when P == 0 && W == 0.

STRH{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

#### Pre-indexed variant

Applies when P == 1 && W == 1.

STRH{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

#### Decode for all variants of this encoding

```
if P == '0' && W == '1' then SEE STRHT;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

## T1

15	14	13	12	11	10		6	5		3	2	0	
1	0	0	0	0	0	imm5	Rn					Rt	

### T1 variant

STRH{<C>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

### Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm5:'0', 32);
index = TRUE; add = TRUE; wback = FALSE;
```

## T2

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11				0

### Offset variant

Applies when P == 1 && U == 0 && W == 0.

STRH{<C>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

### Post-indexed variant

Applies when P == 0 && W == 1.

STRH{<C>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

### Pre-indexed variant

Applies when P == 1 && W == 1.

STRH{<C>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!

### Decode for all variants of this encoding

```
if P == '1' && U == '1' && W == '0' then SEE STRHT;
if Rn == '1111' || (P == '0' && W == '0') then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<C>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For encoding A1, T1, T2, T3: is the general-purpose base register, encoded in the "Rn" field.
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>
+	Specifies the offset is added to the base register.

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as <imm>/2.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

## Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
```

## F5.1.235 STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses on page F2-2854](#).

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0

    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;

```

## F5.1.236 STRHT

Store Register Halfword Unprivileged stores a halfword from a register to memory. For information about memory accesses see [Memory accesses on page F2-2854](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

### A1

### Assembler symbols

<C> See [Standard assembler syntax fields on page F2-2848](#).

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rt>	For encoding A1 and A2: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.  For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
+/-	For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <div style="margin-left: 40px;"> -           when U = 0  +           when U = 1 </div> For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <div style="margin-left: 40px;"> -           when U = 0  +           when U = 1 </div>
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.
<shift>	The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see <a href="#">Shifts applied to a register on page F2-2852</a> .
+	Specifies the offset is added to the base register.
<imm>	For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.  For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

## Operation for all encodings

```

if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;           // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    if t == 15 then // Only possible for encodings A1 and A2
        data = PCStoreValue();
    else
        data = R[t];
    MemU_unpriv[address,4] = data;
    if postindex then R[n] = offset_addr;

```

## CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as STR (immediate).

## F5.1.238 SUB (immediate, from PC)

Subtract from PC subtracts an immediate value from the `Align(PC, 4)` value to form a PC-relative address, and writes the result to the destination register. ARM recommends that, where possible, software avoids using this alias.

This instruction is an alias of the [ADR](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ADR](#).
- The description of [ADR](#) gives the operational pseudocode for this instruction.

### A2

31	28	27	26	25	24	23	22	21	20	19	18	17	16	15	12	11			0
!=1111				0	0	1	0	0	1	1	1	1	Rd		imm12				
cond																			

### A2 variant

`SUB{<c>}{<q>} <Rd>, PC, #<const>`

is equivalent to

`ADR{<c>}{<q>} <Rd>, <label>`

and is the preferred disassembly when `imm12 == '000000000000'`.

### T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	12	11	8	7			0
1	1	1	1	0	i	1	0	1	0	1	0	1	1	1	1	0	imm3		Rd		imm8			

### T2 variant

`SUB{<c>}{<q>} <Rd>, PC, #<imm12>`

is equivalent to

`ADR{<c>}{<q>} <Rd>, <label>`

and is the preferred disassembly when `i:imm3:imm8 == '000000000000'`.

## Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<Rd> For encoding A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733](#).

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field.

<label> For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label.

If the offset is zero or positive, encoding A1 is used, with `imm32` equal to the offset.

If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are any of the constants described in *Modified immediate constants in A32 instructions on page F2-2864*.

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label.

If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset.

If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are 0-4095.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> An immediate value. See *Modified immediate constants in A32 instructions on page F2-2864* for the range of values.

## Operation for all encodings

The description of [ADR](#) gives the operational pseudocode for this instruction.

## F5.1.239 SUB, SUBS (immediate)

Subtract (immediate) subtracts an immediate value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR\_<current\_mode>.
  - The PE checks SPSR\_<current\_mode> for an illegal return event. See [Illegal return events from AArch32 state on page G1-4361](#).
  - The instruction is UNDEFINED in Hyp mode, except for encoding T5 with <imm8> set to zero, which is the encoding for the ERET instruction, see [ERET](#).
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *SUBS PC, LR and related instructions (A32)* on page K1-6109 and *SUBS PC, LR and related instructions (T32)* on page K1-6109.

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rdn>	Is the general-purpose source and destination register, encoded in the "Rdn" field.
<imm8>	For encoding T2: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. For encoding T5: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. If <Rn> is the LR, and zero is used, see <a href="#">ERET</a> .
<Rd>	For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used: <ul style="list-style-type: none"> <li>For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see <a href="#">Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733</a>.</li> <li>For the SUBS variant, the instruction performs an exception return, that restores <a href="#">PSTATE</a> from SPSR_&lt;current_mode&gt;. ARM deprecates use of this instruction unless &lt;Rn&gt; is the LR.</li> </ul> For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
<Rn>	For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see <a href="#">SUB, SUBS (SP minus immediate)</a> . If the PC is used, see <a href="#">ADR</a> . For encoding T1: is the general-purpose source register, encoded in the "Rn" field. For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see <a href="#">SUB, SUBS (SP minus immediate)</a> .
<imm3>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2864](#) for the range of values.

For encoding T3: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2863](#) for the range of values.

In the T32 instruction set, MOV{<c>}{<q>} PC, LR is a pseudo-instruction for SUBS{<c>}{<q>} PC, LR, #0.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzc) = AddWithCarry(R[n], NOT(imm32), '1');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzc;
```

## F5.1.240 SUB, SUBS (register)

Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR\_<current\_mode>.
  - The PE checks SPSR\_<current\_mode> for an illegal return event. See [Illegal return events from AArch32 state on page G1-4361](#).
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

#### Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

#### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

#### Assembler symbols

<C>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.
<type>	Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <ul style="list-style-type: none"> <li>LSL when type = 00</li> <li>LSR when type = 01</li> <li>ASR when type = 10</li> <li>ROR when type = 11</li> </ul>
<Rs>	Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcvc) = AddWithCarry(R[n], NOT(shifted), '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcvc;
```

## F5.1.242 SUB, SUBS (SP minus immediate)

Subtract from SP (immediate) subtracts an immediate value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR\_<current\_mode>.
  - The PE checks SPSR\_<current\_mode> for an illegal return event. See [Illegal return events from AArch32 state on page G1-4361](#).
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

### Decode for this encoding

```
d = UInt(Rd); setFlags = FALSE; imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE;
```

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<imm7>	Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.
<Rd>	For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. If the PC is used: <ul style="list-style-type: none"> <li>For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see <a href="#">Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733</a>.</li> </ul>

- For the SUBS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR\_<current\_mode>. ARM deprecates use of this instruction unless <Rn> is the LR.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2864](#) for the range of values.

For encoding T2: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2863](#) for the range of values.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcvc) = AddWithCarry(SP, NOT(imm32), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcvc;
```

## F5.1.243 SUB, SUBS (SP minus register)

Subtract from SP (register) subtracts an optionally-shifted register value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR\_<current\_mode>.
  - The PE checks SPSR\_<current\_mode> for an illegal return event. See [Illegal return events from AArch32 state on page G1-4361](#).
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2733](#).
- For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR\_<current\_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

	For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <div> <div>LSL          when type = 00</div> <div>LSR          when type = 01</div> <div>ASR          when type = 10</div> <div>ROR          when type = 11</div> </div>
<amount>	For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.  For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcvc) = AddWithCarry(SP, NOT(shifted), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcvc;

```

**————— Note —————**

Software can use this instruction as a call to an operating system to provide a service.

- If the SVC is executed in Hyp mode.
- If `HCR.TGE` is set to 1, and the SVC is executed in Non-secure User mode. For more information, see *Supervisor Call exception, when the value of HCR.TGE is 1* on page G1-4357

- If the SVC is unconditional:
  - For the T32 instruction, is the zero-extended value of the `imm8` field.
  - For the A32 instruction, is the least-significant 16 bits the `imm24` field.
- If the SVC is conditional, is UNKNOWN.

**A1**

**A1 variant**

SVC{<c>}{<q>} {#}<imm>

**Decode for this encoding**

```
imm32 = ZeroExtend(imm24, 32);
```

## T1

### ***T1 variant***

SVC{<c>}{<q>} {#}<imm>

**Decode for this encoding**

```
imm32 = ZeroExtend(imm8, 32);
```

## Assembler symbols

<C> See *Standard assembler syntax fields* on page F2-2848.

- <q> See [Standard assembler syntax fields on page F2-2848](#).
- <imm> For encoding A1: is a 24-bit unsigned immediate, in the range 0 to 16777215, encoded in the "imm24" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm24 in software, for example to determine the required service.
- For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm8 in software, for example to determine the required service.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CallSupervisor(imm32<15:0>);
```

## F5.1.245 SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

#### T2 variant

SXTB{<c>}.W {<Rd>}, {<Rm>} // <Rd>, <Rm> can be represented in T1  
SXTB{<c>}{<q>} {<Rd>}, {<Rm>}, {, ROR #<amount>}

#### Decode for this encoding

```
d = UInt(Rd); m = UInt(Rm); rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	Is the general-purpose source register, encoded in the "Rm" field.
<amount>	Is the rotate amount, encoded in the "rotate" field. It can have the following values: (omitted)    when rotate = 00 8            when rotate = 01 16           when rotate = 10 24           when rotate = 11

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = SignExtend(rotated<7:0>, 32);
```

## F5.1.249 SXTB16

Signed Extend Byte 16 extracts two 8-bit values from a register, sign-extends them to 16 bits each, and writes the results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

### A1

31	28	27	26	25	24	23	22	21	20	19	18	17	16	15	12	11	10	9	8	7	6	5	4	3	0

cond																									

#### A1 variant

SXTB16{<c>}{<q>} {<Rd>}, {<Rm>}, ROR #<amount>}

#### Decode for this encoding

```
d = UInt(Rd); m = UInt(Rm); rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	8	7	6	5	4	3	0
1	1	1	1	1	0	1	0	0	0	1	0	1	1	1	1	1	1	1	1	Rd	1	(0)	rotate		Rm		

#### T1 variant

SXTB16{<c>}{<q>} {<Rd>}, {<Rm>}, ROR #<amount>}

#### Decode for this encoding

```
d = UInt(Rd); m = UInt(Rm); rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	Is the general-purpose source register, encoded in the "Rm" field.
<amount>	Is the rotate amount, encoded in the "rotate" field. It can have the following values:
(omitted)	when rotate = 00
8	when rotate = 01
16	when rotate = 10
24	when rotate = 11

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d]<15:0> = SignExtend(rotated<7:0>, 16);
    R[d]<31:16> = SignExtend(rotated<23:16>, 16);
```

## F5.1.250 SXTB

Signed Extend Halfword extracts a 16-bit value from a register, sign-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

### A1

31	28	27	26	25	24	23	22	21	20	19	18	17	16	15	12	11	10	9	8	7	6	5	4	3	0

SXTB{<c>}{<q>} {<Rd>}, {<Rm>}, {, ROR #<amount>}

#### Decode for this encoding

d = UInt(Rd); m = UInt(Rm); rotation = UInt(rotate:'000');  
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	Is the general-purpose source register, encoded in the "Rm" field.
<amount>	Is the rotate amount, encoded in the "rotate" field. It can have the following values: (omitted)    when rotate = 00 8            when rotate = 01 16           when rotate = 10 24           when rotate = 11

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = SignExtend(rotated<15:0>, 32);
```

## F5.1.251 TBB, TBH

Table Branch Byte or Halfword causes a PC-relative forward branch using a table of single byte or halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value returned from the table.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	14	13	12	11	10	9	8	7	6	5	4	3	0
1	1	1	0	1	0	0	0	1	1	0	1	Rn	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	H	Rm		

#### Byte variant

Applies when H == 0.

TBB{<c>}{<q>} [<Rn>, <Rm>] // Outside or last in IT block

#### Halfword variant

Applies when H == 1.

TBH{<c>}{<q>} [<Rn>, <Rm>, LSL #1] // Outside or last in IT block

#### Decode for all variants of this encoding

```
n = UInt(Rn); m = UInt(Rm); is_tbh = (H == '1');
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

#### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

#### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rn>	Is the general-purpose base register holding the address of the table of branch lengths, encoded in the "Rn" field. The PC can be used. If it is, the table immediately follows this instruction.
<Rm>	For the byte variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.  For the halfword variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

#### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if is_tbh then
        halfwords = UInt(MemU[R[n]+LSL(R[m],1), 2]);
    else
        halfwords = UInt(MemU[R[n]+R[m], 1]);
    BranchWritePC(PC + 2*halfwords);
```

## F5.1.252 TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	14	13	12	11				0											
!=1111		0		0		1		1		0		0		1		1		Rn		(0)		(0)		(0)		(0)		imm12			
cond																															

### A1 variant

TEQ{<c>}{<q>} <Rn>, #<const>

### Decode for this encoding

```
n = UInt(Rn);
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	14	12	11	10	9	8	7				0
1	1	1	1	0	i	0	0	1	0	0	1		Rn	0	imm3	1	1	1	1						imm8

### T1 variant

TEQ{<c>}{<q>} <Rn>, #<const>

### Decode for this encoding

```
n = UInt(Rn);
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rn>	For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
<const>	For encoding A1: an immediate value. See <a href="#">Modified immediate constants in A32 instructions on page F2-2864</a> for the range of values. For encoding T1: an immediate value. See <a href="#">Modified immediate constants in T32 instructions on page F2-2863</a> for the range of values.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

### F5.1.253 TEQ (register)

Test Equivalence (register) performs a bitwise exclusive OR operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

#### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	14	13	12	11	7	6	5	4	3	0
!=1111	0	0	0	1	0	0	1	1		Rn	(0)	(0)	(0)	(0)		imm5	type	0		Rm		
cond																						

#### **Rotate right with extend variant**

Applies when imm5 == 00000 && type == 11.

TEQ{<c>}{<q>} <Rn>, <Rm>, RRX

#### **Shift or rotate by value variant**

Applies when !(imm5 == 00000 && type == 11).

TEQ{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

#### **Decode for all variants of this encoding**

```
n = UInt(Rn); m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

#### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	14	12	11	10	9	8	7	6	5	4	3	0
1	1	1	0	1	0	1	0	1	0	0	1	Rn	(0)	imm3	1	1	1	1	imm2	type					Rm	

#### **Rotate right with extend variant**

Applies when imm3 == 000 && imm2 == 00 && type == 11.

TEQ{<c>}{<q>} <Rn>, <Rm>, RRX

#### **Shift or rotate by value variant**

Applies when !(imm3 == 000 && imm2 == 00 && type == 11).

TEQ{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

#### **Decode for all variants of this encoding**

```
n = UInt(Rn); m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

#### **Notes for all encodings**

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

#### **Assembler symbols**

<c> See [Standard assembler syntax fields on page F2-2848](#).

<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<Rn>	For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.
<Rm>	For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <div> <div>LSL</div> <div>when type = 00</div> </div> <div> <div>LSR</div> <div>when type = 01</div> </div> <div> <div>ASR</div> <div>when type = 10</div> </div> <div> <div>ROR</div> <div>when type = 11</div> </div>
<amount>	For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged

```

### F5.1.254 TEQ (register-shifted register)

Test Equivalence (register-shifted register) performs a bitwise exclusive OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

#### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	14	13	12	11	8	7	6	5	4	3	0
!=1111	0	0	0	1	0	0	1	1	Rn	(0)	(0)	(0)	(0)	Rs	0	type	1	Rm					
cond																							

#### A1 variant

TEQ{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

#### Decode for this encoding

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

#### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

#### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .								
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .								
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.								
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.								
<type>	Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <table> <tr> <td>LSL</td><td>when type = 00</td></tr> <tr> <td>LSR</td><td>when type = 01</td></tr> <tr> <td>ASR</td><td>when type = 10</td></tr> <tr> <td>ROR</td><td>when type = 11</td></tr> </table>	LSL	when type = 00	LSR	when type = 01	ASR	when type = 10	ROR	when type = 11
LSL	when type = 00								
LSR	when type = 01								
ASR	when type = 10								
ROR	when type = 11								
<Rs>	Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.								

#### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

## F5.1.255 TST (immediate)

Test (immediate) performs a bitwise AND operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	14	13	12	11				0
!=1111	0	0	1	1	0	0	0	1		Rn	(0)	(0)	(0)	(0)						imm12
cond																				

### A1 variant

TST{<c>}{<q>} <Rn>, #<const>

### Decode for this encoding

```
n = UInt(Rn);
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	14	12	11	10	9	8	7			0
1	1	1	1	0	i	0	0	0	0	0	1		Rn	0	imm3		1	1	1	1				imm8

### T1 variant

TST{<c>}{<q>} <Rn>, #<const>

### Decode for this encoding

```
n = UInt(Rn);
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rn>	For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
<const>	For encoding A1: an immediate value. See <a href="#">Modified immediate constants in A32 instructions on page F2-2864</a> for the range of values. For encoding T1: an immediate value. See <a href="#">Modified immediate constants in T32 instructions on page F2-2863</a> for the range of values.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

## F5.1.256 TST (register)

Test (register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	14	13	12	11	7	6	5	4	3	0

if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rn>	For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.  For encoding T1 and T2: is the first general-purpose source register, encoded in the "Rn" field.
<Rm>	For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.  For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:  <div style="margin-left: 20px;"> LSL        when type = 00  LSR        when type = 01  ASR        when type = 10  ROR        when type = 11 </div>
<amount>	For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.  For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

## F5.1.257 TST (register-shifted register)

Test (register-shifted register) performs a bitwise AND operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	14	13	12	11	8	7	6	5	4	3	0
!=1111	0	0	0	1	0	0	0	1	Rn	(0)	(0)	(0)	(0)	Rs	0	type	1	Rm					
cond																							

### A1 variant

TST{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

### Decode for this encoding

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .								
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .								
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.								
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.								
<type>	Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <table> <tr> <td>LSL</td><td>when type = 00</td></tr> <tr> <td>LSR</td><td>when type = 01</td></tr> <tr> <td>ASR</td><td>when type = 10</td></tr> <tr> <td>ROR</td><td>when type = 11</td></tr> </table>	LSL	when type = 00	LSR	when type = 01	ASR	when type = 10	ROR	when type = 11
LSL	when type = 00								
LSR	when type = 01								
ASR	when type = 10								
ROR	when type = 11								
<Rs>	Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.								

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

## F5.1.258 UADD16

Unsigned Add 16 performs two 16-bit unsigned integer additions, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results of the additions.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
!=1111		0	1	1	0	0	1	0	1	Rn		Rd		(1)	(1)	(1)	(1)	0	0	0	1	Rm	
cond																							

### A1 variant

UADD16{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

### Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	14	13	12	11	8	7	6	5	4	3	0
1	1	1	1	1	0	1	0	1	0	0	1		Rn	1	1	1	1		Rd	0	1	0	0		Rm

### T1 variant

UADD16{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

### Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<15:0>) + UInt(R[m]<15:0>);
    sum2 = UInt(R[n]<31:16>) + UInt(R[m]<31:16>);
    R[d]<15:0> = sum1<15:0>;
```

```
R[d]<31:16> = sum2<15:0>;  
PSTATE.GE<1:0> = if sum1 >= 0x10000 then '11' else '00';  
PSTATE.GE<3:2> = if sum2 >= 0x10000 then '11' else '00';
```

## F5.1.259 UADD8

Unsigned Add 8 performs four unsigned 8-bit integer additions, and writes the results to the destination register. It sets **PSTATE**.GE according to the results of the additions.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
!=1111		0	1	1	0	0	1	0	1	Rn		Rd		(1)	(1)	(1)	(1)	1	0	0	1	Rm	
cond																							

### A1 variant

UADD8{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>

#### Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

### T1

### T1 variant

UADD8{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>

#### Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<7:0>) + UInt(R[m]<7:0>);
    sum2 = UInt(R[n]<15:8>) + UInt(R[m]<15:8>);
    sum3 = UInt(R[n]<23:16>) + UInt(R[m]<23:16>);
```

```
sum4 = UInt(R[n]<31:24>) + UInt(R[m]<31:24>);
R[d]<7:0> = sum1<7:0>;
R[d]<15:8> = sum2<7:0>;
R[d]<23:16> = sum3<7:0>;
R[d]<31:24> = sum4<7:0>;
PSTATE.GE<0> = if sum1 >= 0x100 then '1' else '0';
PSTATE.GE<1> = if sum2 >= 0x100 then '1' else '0';
PSTATE.GE<2> = if sum3 >= 0x100 then '1' else '0';
PSTATE.GE<3> = if sum4 >= 0x100 then '1' else '0';
```

## F5.1.260 UASX

Unsigned Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer addition and one unsigned 16-bit subtraction, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0

### T1 variant

UASX{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>

### Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff = UInt(R[n]<15:0>) - UInt(R[m]<31:16>);
    sum = UInt(R[n]<31:16>) + UInt(R[m]<15:0>);
```

```
R[d]<15:0> = diff<15:0>;  
R[d]<31:16> = sum<15:0>;  
PSTATE.GE<1:0> = if diff >= 0 then '11' else '00';  
PSTATE.GE<3:2> = if sum >= 0x10000 then '11' else '00';
```

## F5.1.261 UBFX

Unsigned Bit Field Extract extracts any number of adjacent bits at any position from a register, zero-extends them to 32 bits, and writes the result to the destination register.

### A1

31	28	27	26	25	24	23	22	21	20	16	15	12	11	7	6	5	4	3	0
1	1	1	1	1	1	1	1	1	1	widthm1	Rd	lsb	1	0	1	Rn			
cond																			

### A1 variant

UBFX{<C>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

### Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(lsb); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	14	12	11	8	7	6	5	4	0
1	1	1	1	0	(0)	1	1	1	1	0	0	Rn	0	imm3	Rd	imm2	(0)	widthm1					

### T1 variant

UBFX{<C>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

### Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(imm3:imm2); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<C>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the general-purpose source register, encoded in the "Rn" field.
<lsb>	For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.  For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.
<width>	Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsb + widthminus1;
    if msbit <= 31 then
        R[d] = ZeroExtend(R[n]<msbit:lsb>, 32);
    else
        UNPREDICTABLE;
```

## CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

## F5.1.262 UDF

Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED in the ARMv8-A architecture. However:

- With the T32 instruction set, ARM deprecates using the UDF instruction in an IT block.
- In the A32 instruction set, UDF is not conditional.

### A1

31	28	27	26	25	24	23	22	21	20	19				8	7	6	5	4	3	0
1	1	1	0	0	1	1	1	1	1	1										
cond											imm12				1	1	1	1	imm4	

#### A1 variant

UDF{<C>}{<q>} {#}<imm>

#### Decode for this encoding

```
imm32 = ZeroExtend(imm12:imm4, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

### T1

15	14	13	12	11	10	9	8	7		0
1	1	0	1	1	1	1	0	imm8		

#### T1 variant

UDF{<C>}{<q>} {#}<imm>

#### Decode for this encoding

```
imm32 = ZeroExtend(imm8, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

### T2

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	14	13	12	11			0
1	1	1	1	0	1	1	1	1	1	1	1	1		imm4	1	0	1	0	imm12		

#### T2 variant

UDF{<C>}.W {#}<imm> // <imm> can be represented in T1  
UDF{<C>}{<q>} {#}<imm>

#### Decode for this encoding

```
imm32 = ZeroExtend(imm4:imm12, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

## Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). <c> must be AL or omitted.  
For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2848](#). ARM deprecates using any <c> value other than AL.
- <q> See [Standard assembler syntax fields on page F2-2848](#).
- <imm> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. The PE ignores the value of this constant.  
For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. The PE ignores the value of this constant.  
For encoding T2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. The PE ignores the value of this constant.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    UNDEFINED;
```

## F5.1.263 UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See [Divide instructions on page F1-2819](#) for more information about this instruction.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
!=1111	0	1	1	1	0	0	1	1		Rd	(1)	(1)	(1)	(1)	Rm	0	0	0	1		Rn
cond										Ra											

#### A1 variant

UDIV{<C>}{<q>} {<Rd>}, {<Rn>, <Rm>

#### Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a != 15 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If Ra != '1111', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction performs a divide and the register specified by Ra becomes UNKNOWN.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	8	7	6	5	4	3	0

														Ra									

#### T1 variant

UDIV{<C>}{<q>} {<Rd>}, {<Rn>, <Rm>

#### Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a != 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

#### CONSTRAINED UNPREDICTABLE behavior

If Ra != '1111', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction performs a divide and the register specified by Ra becomes UNKNOWN.

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if UInt(R[m]) == 0 then
        result = 0;
    else
        result = RoundTowardsZero(Real(UInt(R[n])) / Real(UInt(R[m])));
    R[d] = result<31:0>;
```

## F5.1.264 UHADD16

Unsigned Halving Add 16 performs two unsigned 16-bit integer additions, halves the results, and writes the results to the destination register.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0

R[d]<31:24> = diff4<8:1>;
```

## F5.1.270 UMAAL

Unsigned Multiply Accumulate Accumulate Long multiplies two unsigned 32-bit values to produce a 64-bit value, adds two unsigned 32-bit values, and writes the 64-bit result to two registers.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
!=1111	0	0	0	0	0	1	0	0		RdHi		RdLo		Rm		1	0	0	1		Rn
cond																					

### A1 variant

UMAAL{<C>}{<Q>} <RdLo>, <RdHi>, <Rn>, <Rm>

### Decode for this encoding

```
dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm);
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	8	7	6	5	4	3	0
1	1	1	1	1	0	1	1	1	1	0		Rn		RdLo		RdHi		0	1	1	0		Rm

### T1 variant

UMAAL{<C>}{<Q>} <RdLo>, <RdHi>, <Rn>, <Rm>

### Decode for this encoding

```
dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm);
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<RdLo>	Is the general-purpose source register holding the first addend and the destination register for the lower 32 bits of the result, encoded in the "RdLo" field.
<RdHi>	Is the general-purpose source register holding the second addend and the destination register for the upper 32 bits of the result, encoded in the "RdHi" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = UInt(R[n]) * UInt(R[m]) + UInt(R[dHi]) + UInt(R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
```

## F5.1.271 UMLAL, UMLALS

Unsigned Multiply Accumulate Long multiplies two unsigned 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0

cond																					

#### Flag setting variant

Applies when S == 1.

UMLALS{<C>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

#### Not flag setting variant

Applies when S == 0.

UMLAL{<C>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

#### Decode for all variants of this encoding

```
dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	8	7	6	5	4	3	0
1	1	1	1	1	0	1	1	1	1	1	0	Rn	RdLo	RdHi	0	0	0	0	Rm				

#### T1 variant

UMLAL{<C>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

#### Decode for this encoding

```
dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm); setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If  $dHi == dLo$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<RdLo>	Is the general-purpose source register holding the lower 32 bits of the addend, and the destination register for the lower 32 bits of the result, encoded in the "RdLo" field.
<RdHi>	Is the general-purpose source register holding the upper 32 bits of the addend, and the destination register for the upper 32 bits of the result, encoded in the "RdHi" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = UInt(R[n]) * UInt(R[m]) + UInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```

## F5.1.272 UMULL, UMULLS

Unsigned Multiply Long multiplies two 32-bit unsigned values to produce a 64-bit result.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0

if sat1 || sat2 then  
    PSTATE.Q = '1';
```

## F5.1.283 USAX

Unsigned Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results.

### A1

d = UInt(Rd); m = UInt(Rm); rotation = 0;

### T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	8	7	6	5	4	3	0
1	1	1	1	1	0	1	0	0	0	0	1	1	1	1	1	1	1	1	1	Rd	1	(0)	rotate		Rm		

#### T2 variant

UXTH{<c>}.W {<Rd>}, {<Rm> // <Rd>, <Rm> can be represented in T1  
UXTH{<c>}{<q>} {<Rd>}, {<Rm> {, ROR #<amount>}}

#### Decode for this encoding

d = UInt(Rd); m = UInt(Rm); rotation = UInt(rotate:'000');  
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	Is the general-purpose source register, encoded in the "Rm" field.
<amount>	Is the rotate amount, encoded in the "rotate" field. It can have the following values: (omitted)    when rotate = 00 8            when rotate = 01 16           when rotate = 10 24           when rotate = 11

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = ZeroExtend(rotated<15:0>, 32);
```

## F5.1.292 WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see [Wait For Event and Send Event on page G1-4403](#).

As described in [Wait For Event and Send Event on page G1-4403](#), the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level, see:

- [Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-4421](#).
- [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437](#).
- [Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-4447](#).

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
if IsEventRegisterSet() then
    ClearEventRegister();
else
    if PSTATE.EL == EL0 then
        // Check for traps described by the OS which may be EL1 or EL2.
        AArch32.CheckForWfxTrap(EL1, TRUE);
    if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} && !IsInHost() then
        // Check for traps described by the Hypervisor.
        AArch32.CheckForWfxTrap(EL2, TRUE);
    if HaveEL(EL3) && PSTATE.M != M32_Monitor then
        // Check for traps described by the Secure Monitor.
        AArch32.CheckForWfxTrap(EL3, TRUE);
    WaitForEvent();
```

## F5.1.293 WFI

Wait For Interrupt is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. For more information, see [Wait For Interrupt](#) on page G1-4406.

As described in [Wait For Interrupt](#) on page G1-4406, the execution of a WFI instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level, see:

- [Traps to Undefined mode of EL0 execution of WFE and WFI instructions](#) on page G1-4421.
- [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions](#) on page G1-4437.
- [Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode](#) on page G1-4447.

    if HaveEL(EL3) && PSTATE.M != M32_Monitor then
        // Check for traps described by the Secure Monitor.
        AArch32.CheckForWfxTrap(EL3, FALSE);
    WaitForInterrupt();
```

## F5.1.294 YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see [The Yield instruction on page F1-2825](#).

    Hint_Yield();
```

## F5.2 Encoding and use of Banked register transfer instructions

Software executing at EL1 or higher can use the MRS (Banked register) and MSR (Banked register) instructions to transfer values between the general-purpose registers and Special-purpose registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- [Register arguments in the Banked register transfer instructions.](#)
- [Usage restrictions on the Banked register transfer instructions on page F5-3675.](#)
- [Encoding the register argument in the Banked register transfer instructions on page F5-3676.](#)
- [Pseudocode support for the Banked register transfer instructions on page F5-3677.](#)

For descriptions of the instructions see [MRS \(Banked register\) on page F5-3277](#) and [MSR \(Banked register\) on page F5-3281](#).

### F5.2.1 Register arguments in the Banked register transfer instructions

Figure F5-1 shows the Banked general-purpose registers and Special-purpose registers:

Associated PE mode								
	User or System	Hyp	Supervisor	Abort	Undefined	Monitor	IRQ	FIQ
General-purpose registers	R8_usr							R8_fiq
	R9_usr							R9_fiq
	R10_usr							R10_fiq
	R11_usr							R11_fiq
	R12_usr							R12_fiq
	SP_usr	SP_hyp	SP_svc	SP_abt	SP_und	SP_mon	SP_irq	SP_fiq
Special-purpose registers	LR_usr		LR_svc	LR_abt	LR_und	LR_mon	LR_irq	LR_fiq
		SPSR_hyp	SPSR_svc	SPSR_abt	SPSR_und	SPSR_mon	SPSR_irq	SPSR_fiq
		ELR_hyp						

For the general-purpose registers, if no other register is shown, the *current mode register* is the \_usr register. So, for example, the full set of current mode registers, including the registers that are not banked:

- For Hyp mode, is {R0\_usr - R12\_usr, SP\_hyp, LR\_usr, SPSR\_hyp, ELR\_hyp}.
- For Abort mode, is {R0\_usr - R12\_usr, SP\_abt, LR\_abt, SPSR\_abt}.

#### Figure F5-1 Banking of general-purpose and Special-purpose registers

Figure F5-1 is based on [Figure G1-2 on page G1-4325](#), that shows the complete set of general-purpose registers and Special-purpose registers accessible in each mode.

#### Note

- System mode uses the same set of registers as User mode. Neither of these modes can access an SPSR, except that System mode can use the MRS (Banked register) and MSR (Banked register) instructions to access some SPSRs, as described in [Usage restrictions on the Banked register transfer instructions on page F5-3675](#).
- General-purpose registers R0-R7, that are not Banked, cannot be accessed using the MRS (Banked register) and MSR (Banked register) instructions.
- In addition to the registers shown in [Figure F5-1](#), the DLR and DSPSR are AArch32 System registers that map onto the AArch64 Special-purpose registers DLR\_EL0 and DSPSR\_EL0. However, DLR and DSPSR are not accessible using the MRS (Banked register) and MSR (Banked register) instructions.

Software using an MRS (Banked register) or MSR (Banked register) instruction specifies one of these registers using a name shown in [Figure F5-1](#), or an alternative name for SP or LR. These registers can be grouped as follows:

**R8-R12** Each of these registers has two Banked copies, \_usr and \_fiq, for example R8\_usr and R8\_fiq.

<b>SP</b>	There is a Banked copy of SP for every mode except System mode. For example, SP_svc is the SP for Supervisor mode.
<b>LR</b>	There is a Banked copy of LR for every mode except System mode and Hyp mode. For example, LR_svc is the LR for Supervisor mode.
<b>SPSR</b>	There is a Banked copy of <a href="#">SPSR</a> for every mode except System mode and User mode.
<b>ELR_hyp</b>	Except for the operations provided by MRS (Banked register) and MSR (Banked register), <a href="#">ELR_hyp</a> is accessible only from Hyp mode. It is not Banked.

## F5.2.2 Usage restrictions on the Banked register transfer instructions

MRS (Banked register) and MSR (Banked register) instructions are CONSTRAINED UNPREDICTABLE if any of the following applies:

- The instruction is executed in User mode.
- The instruction accesses a Banked register that is not implemented, or that either:
  - Is not accessible from the current Privilege level and Security state.
  - Can be accessed from the current mode by using a different instruction.

[MSR/MRS Banked registers on page K1-6117](#) describes the permitted CONSTRAINED UNPREDICTABLE behavior.

An MRS (Banked register) or an MSR (Banked register) executed:

- At Non-secure EL1 cannot access any Hyp mode Banked registers.
- At Non-secure EL1 or EL2 cannot access any Monitor mode Banked registers.
- In a Secure mode other than Monitor mode cannot access any Hyp Banked registers.

This means that the Banked registers that MRS (Banked register) and MSR (Banked register) instructions cannot access are:

### From Monitor mode

- The current mode registers R8\_usr-R12\_usr, SP\_mon, LR\_mon, and SPSR\_mon.

### From Hyp mode

- The Monitor mode registers SP\_mon, LR\_mon, and SPSR\_mon.
- The current mode registers R8\_usr-R12\_usr, SP\_hyp, LR\_usr, and SPSR\_hyp.

### ———— Note ————

MRS (Banked register) and MSR (Banked register) instructions can access the current mode register [ELR\\_hyp](#).

### From FIQ mode

- From Non-secure EL1, the Monitor mode registers SP\_mon, LR\_mon, and SPSR\_mon.
- The Hyp mode registers SP\_hyp, SPSR\_hyp, and [ELR\\_hyp](#).
- The current mode registers R8\_fiq-R12\_fiq, SP\_fiq, LR\_fiq, and SPSR\_fiq.

### From System mode

- From Non-secure EL1, the Monitor mode registers SP\_mon, LR\_mon, and SPSR\_mon.
- The Hyp mode registers SP\_hyp, SPSR\_hyp, and [ELR\\_hyp](#).
- The current mode registers R8\_usr-R12\_usr, SP\_usr, and LR\_usr.

### From Supervisor mode, Abort mode, Undefined mode, and IRQ mode

- From Non-secure EL1, the Monitor mode registers SP\_mon, LR\_mon, and SPSR\_mon.
- The Hyp mode registers SP\_hyp, SPSR\_hyp, and [ELR\\_hyp](#).
- The current mode registers R8\_usr-R12\_usr, SP\_<current\_mode>, LR\_<current\_mode>, and SPSR\_<current\_mode>.

If EL3 is using AArch64, all MRS (Banked register) and MSR (Banked register) accesses to the Monitor mode registers from Secure EL1 modes are trapped to EL3. See [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32](#) on page D1-1870.

For more information, see:

- [Encoding the register argument in the Banked register transfer instructions.](#)
- [Pseudocode support for the Banked register transfer instructions](#) on page F5-3677.
- [MRS \(Banked register\)](#) on page F5-3277.
- [MSR \(Banked register\)](#) on page F5-3281.

#### ————— Note —————

CONSTRAINED UNPREDICTABLE behavior must not give access to registers that are not accessible from the current Privilege level and Security state.

### F5.2.3 Encoding the register argument in the Banked register transfer instructions

The MRS (Banked register) and MSR (Banked register) instructions include a 5-bit field, SYSm, and an R bit, that together encode the register argument for the instruction.

When the R bit is set to 0, the argument is a register other than a Banked copy of the [SPSR](#), and [Table F5-1](#) shows how the SYSm field defines the required register argument. In this table, CONST. UNPREDICTABLE indicates that behavior is CONSTRAINED UNPREDICTABLE.

**Table F5-1 Banked register encodings when R==0**

SYSm<2:0>	SYSm<4:3>			
	0b00	0b01	0b10	0b11
0b000	R8_usr	R8_fiq	LR_irq	CONST. UNPREDICTABLE
0b001	R9_usr	R9_fiq	SP_irq	CONST. UNPREDICTABLE
0b010	R10_usr	R10_fiq	LR_svc	CONST. UNPREDICTABLE
0b011	R11_usr	R11_fiq	SP_svc	CONST. UNPREDICTABLE
0b100	R12_usr	R12_fiq	LR_abt	LR_mon
0b101	SP_usr	SP_fiq	SP_abt	SP_mon
0b110	LR_usr	LR_fiq	LR_und	<a href="#">ELR_hyp</a>
0b111	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	SP_und	SP_hyp

When the R bit is set to 1, the argument is a Banked copy of the [SPSR](#), and [Table F5-2](#) shows how the SYSm field defines the required register argument. In this table, CONST. UNPREDICTABLE indicates that behavior is CONSTRAINED UNPREDICTABLE.

**Table F5-2 Banked register encodings when R==1**

SYSm<2:0>	SYSm<4:3>			
	0b00	0b01	0b10	0b11
0b000	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	SPSR_irq	CONST. UNPREDICTABLE
0b001	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE
0b010	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	SPSR_svc	CONST. UNPREDICTABLE

**Table F5-2 Banked register encodings when R==1 (continued)**

SYSm<2:0>	SYSm<4:3>			
	0b00	0b01	0b10	0b11
0b011	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE
0b100	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	SPSR_abt	SPSR_mon
0b101	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE
0b110	CONST. UNPREDICTABLE	SPSR_fiq	SPSR_und	SPSR_hyp
0b111	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE	CONST. UNPREDICTABLE

#### F5.2.4 Pseudocode support for the Banked register transfer instructions

The pseudocode functions [BankedRegisterAccessValid\(\)](#) and [SPSRAccessValid\(\)](#) check the validity of MRS (Banked register) and MSR (Banked register) accesses. That is, they filter the accesses that are CONSTRAINED UNPREDICTABLE either because:

- They attempt to access a register that [Usage restrictions on the Banked register transfer instructions on page F5-3675](#) shows is not accessible.
- They use an SYSm<4:0> encoding that [Encoding the register argument in the Banked register transfer instructions on page F5-3676](#) shows as CONSTRAINED UNPREDICTABLE.

[BankedRegisterAccessValid\(\)](#) applies to accesses to the banked general-purpose registers, or to [ELR\\_hyp](#), and [SPSRAccessValid\(\)](#) applies to accesses to the [SPSRs](#).

# Chapter F6

## T32 and A32 Advanced SIMD and floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- [Alphabetical list of floating-point and Advanced SIMD instructions on page F6-3680.](#)

---

### **Note**

---

Some headings in this chapter use the term *floating-point register*. This is an abbreviated description, and means a register in the Advanced SIMD and floating-point register file.

---

## F6.1 Alphabetical list of floating-point and Advanced SIMD instructions

This section lists every floating-point and Advanced SIMD instruction in the T32 and A32 instruction sets. For details of the format used see [Format of instruction descriptions on page F2-2844](#).

This section is formatted so that each instruction description starts on a new page.

## F6.1.1 AESD

AES single round decryption.

### A1

if InITBlock() then UNPREDICTABLE;
```

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

- <dt> Is the data type, encoded in the "size" field. It can have the following values:
- 8 when size = 00
- The following encodings are reserved:
- size = 01.
  - size = 1x.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>\*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>\*2.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    op1 = Q[d>>1]; op2 = Q[m>>1];
    Q[d>>1] = AESInvSubBytes(AESInvShiftRows(op1 EOR op2));
```

## F6.1.2 AESE

AES single round encryption.

    Q[d>>1] = AESMixColumns(Q[m>>1]);
```

## F6.1.5 FLDM\*X (FLDMDBX, FLDMIAX)

FLDMDBX is the Decrement Before variant of this instruction, and FLDMIAX is the Increment After variant. FLDM\*X loads multiple SIMD&FP registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

ARM deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7					1	0	
!=1111	1	1	0	P	U	D	W	1		Rn		Vd	1	0	1	1		imm8<7:1>					1		
cond										imm8<0>															

#### Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>

#### Increment After variant

Applies when P == 0 && U == 1.

FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

#### Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VLDR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;

```

#### CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

## T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	10	9	8	7					1	0

if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;

```

### CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move on page F3-2894](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move on page F4-2973](#) for the A32 instruction set.

### Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<Rn>	Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
!	Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
<dreglist>	Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4]; address = address+4;
        else
            word1 = MemA[address,4]; word2 = MemA[address+4,4]; address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;

```

## F6.1.6 FSTMDBX, FSTMIAX

FSTMX stores multiple SIMD&FP registers from the Advanced SIMD and floating-point register file to consecutive locations in using an address from a general-purpose register.

ARM deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

#### Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

FSTMDBX{<c>}{<q>} <Rn>!, <dreglist>

#### Increment After variant

Applies when P == 0 && U == 1.

FSTMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

#### Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FSTMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;

```

#### CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

## T1

### Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

FSTMDBX{<c>}{<q>} <Rn>!, <dreglist>

### Increment After variant

Applies when P == 0 && U == 1.

FSTMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

### Decode for all variants of this encoding

```

## F6.1.17 VABA

Vector Absolute Difference and Accumulate subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand and result elements are all integers of the same length.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

            op2 = Elem[Din[m+r],e,esize];
            absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + absdiff;
            else
                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + absdiff;

```

## F6.1.19 VABD (floating-point)

Vector Absolute Difference (floating-point) subtracts the elements of one vector from the corresponding elements of another vector, and places the absolute values of the results in the elements of the destination vector.

Operand and result elements are floating-point numbers of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

            when 64 D[d] = FPAbs(D[m]);

```

## F6.1.23 VACGE

Vector Absolute Compare Greater Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements are floating-point numbers. The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

This instruction is used by the pseudo-instruction VACLE. The pseudo-instruction is never the preferred disassembly.

<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDorVFPEEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        for r = 0 to regs-1
            for e = 0 to elements-1
                Elem[D[d+r],e,esize] = FPAdd(Elem[D[n+r],e,esize], Elem[D[m+r],e,esize],
                                                StandardFPSCRValue());
    else // VFP instruction
        case esize of
            when 16
                S[d] = Zeros(16) : FPAdd(S[n]<15:0>, S[m]<15:0>, FPSCR);
            when 32
                S[d] = FPAdd(S[n], S[m], FPSCR);
            when 64
                D[d] = FPAdd(D[n], D[m], FPSCR);

```

## F6.1.28 VADD (integer)

Vector Add (integer) adds corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

#### Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields](#) on page F2-2848.

<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<dt>	Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values: I8            when size = 00 I16          when size = 01 I32          when size = 10 I64          when size = 11
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = Elem[D[n+r],e,esize] + Elem[D[m+r],e,esize];

```

## F6.1.29 VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. For rounded results, see [VRADDHN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### F6.1.32 VAND (immediate)

Vector Bitwise AND (immediate) performs a bitwise AND between a register value and an immediate value, and returns the result into the destination vector

This instruction is a pseudo-instruction of the [VBIC \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VBIC \(immediate\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VBIC \(immediate\)](#) gives the operational pseudocode for this instruction.

#### A1

#### Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.  
For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	An optional data type. It is ignored by assemblers, and does not affect the encoding.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND D[m+r];
```

### F6.1.34 VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

This instruction is used by the pseudo-instruction VAND (immediate). The pseudo-instruction is never the preferred disassembly.

## Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate](#) on page F3-2912 for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) on page F4-2994 for the A32 instruction set.

## Assembler symbols

<c> For encoding A1 and A2: see [Standard assembler syntax fields](#) on page F2-2848. This encoding must be unconditional.

For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>\*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<imm> Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2865](#).

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] AND NOT(imm64);
```

### F6.1.35 VBIC (register)

Vector Bitwise Bit Clear (register) performs a bitwise AND between a register value and the complement of a register value, and places the result in the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### F6.1.39 VCEQ (immediate #0)

Vector Compare Equal to Zero takes each element in a vector, and compares it with zero. If it is equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### CONSTRAINED UNPREDICTABLE behavior

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<C>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	For encoding A1 and T1: is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values: <div style="margin-left: 20px;"> S8           when U = 0, size = 00  S16          when U = 0, size = 01  S32          when U = 0, size = 10  U8           when U = 1, size = 00  U16          when U = 1, size = 01  U32          when U = 1, size = 10 </div> For encoding A2 and T2: is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: <div style="margin-left: 20px;"> F32          when sz = 0  F16          when sz = 1 </div>
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```

enumeration VCGEType {VCGEType_signed, VCGEType_unsigned, VCGEType_fp};

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize]; op2 = Elem[D[m+r],e,esize];
            case type of
                when VCGEType_signed    test_passed = (SInt(op1) >= SInt(op2));

```

```
when VCGEtype_unsigned test_passed = (UInt(op1) >= UInt(op2));  
when VCGEtype_fp        test_passed = FPCompareGE(op1, op2, StandardFPSCRValue());  
Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

## F6.1.43 VCGT (immediate #0)

Vector Compare Greater Than Zero takes each element in a vector, and compares it with zero. If it is greater than zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

## F6.1.46 VCLE (register)

Vector Compare Less Than or Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros

This instruction is a pseudo-instruction of the [VCGE \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VCGE \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VCGE \(register\)](#) gives the operational pseudocode for this instruction.

### 64-bit SIMD vector variant

Applies when Q == 0.

VCLE{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

is equivalent to

VCGE{<c>}{<q>}.<dt> <Dd>, <Dm>, <Dn>

and is never the preferred disassembly.

### 128-bit SIMD vector variant

Applies when Q == 1.

$\text{VCLE}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \{ \langle Qd \rangle, \} \langle Qn \rangle, \langle Qm \rangle$

is equivalent to

$\text{VCGE}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \langle Qd \rangle, \langle Qm \rangle, \langle Qn \rangle$

and is never the preferred disassembly.

## Assembler symbols

$\langle Dm \rangle$	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
$\langle Dn \rangle$	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
$\langle Qm \rangle$	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as $\langle Qm \rangle * 2$ .
$\langle Qn \rangle$	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as $\langle Qn \rangle * 2$ .
$\langle c \rangle$	For encoding A1 and A2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1 and T2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
$\langle q \rangle$	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
$\langle dt \rangle$	For encoding A1 and T1: is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values: <div style="margin-left: 20px;"> S8            when U = 0, size = 00  S16          when U = 0, size = 01  S32          when U = 0, size = 10  U8            when U = 1, size = 00  U16          when U = 1, size = 01  U32          when U = 1, size = 10 </div> For encoding A2 and T2: is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: <div style="margin-left: 20px;"> F32            when sz = 0  F16            when sz = 1 </div>
$\langle Qd \rangle$	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as $\langle Qd \rangle * 2$ .
$\langle Dd \rangle$	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

## Operation for all encodings

The description of [VCGE \(register\)](#) gives the operational pseudocode for this instruction.

## F6.1.47 VCLS

Vector Count Leading Sign Bits counts the number of consecutive bits following the topmost bit, that are the same as the topmost bit, in each element in a vector, and places the results in a second vector. The count does not include the topmost bit itself.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit signed integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

## F6.1.48 VCLT (immediate #0)

Vector Compare Less Than Zero takes each element in a vector, and compares it with zero. If it is less than zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.										
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.										

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                bits(esize) zero = FPZero('0');
                test_passed = FPCompareGT(zero, Elem[D[m+r],e,esize], StandardFPSCRValue());
            else
                test_passed = (SInt(Elem[D[m+r],e,esize]) < 0);
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

## F6.1.49 VCLT (register)

Vector Compare Less Than takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros

This instruction is a pseudo-instruction of the [VCGT \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VCGT \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VCGT \(register\)](#) gives the operational pseudocode for this instruction.

## Operation for all encodings

The description of [VCGT \(register\)](#) gives the operational pseudocode for this instruction.

## F6.1.50 VCLZ

Vector Count Leading Zeros counts the number of consecutive zeros, starting from the most significant bit, in each element in a vector, and places the results in a second vector.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = CountLeadingZeroBits(Elem[M[m+r],e,esize])<esize-1:0>;
```

## F6.1.51 VCMF

Vector Compare compares two floating-point registers, or one floating-point register and zero. It writes the result to the **FPSR** flags. These are normally transferred to the **PSTATE**. {N, Z, C, V} Condition flags by a subsequent **VMRS** instruction.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

Depending on settings in the **CPACR**, **NSACR**, and **HCPTR** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

  when '10' esize = 32; d = UInt(Vd:D);
  when '11' esize = 64; d = UInt(D:Vd);

```

### CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<C>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

## NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the [FPSCR](#) flags being set as N=0, Z=0, C=1 and V=1.

VCMPF raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    case esize of
        when 16
            bits(16) op16 = if with_zero then FPZero('0') else S[m]<15:0>;
            FPSCR.<N,Z,C,V> = FPCompare(S[d]<15:0>, op16, quiet_nan_exc, FPSCR);
        when 32
            bits(32) op32 = if with_zero then FPZero('0') else S[m];
            FPSCR.<N,Z,C,V> = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
        when 64
            bits(64) op64 = if with_zero then FPZero('0') else D[m];
            FPSCR.<N,Z,C,V> = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);

```

## F6.1.52 VCMPE

Vector Compare, raising Invalid Operation on NaN compares two floating-point registers, or one floating-point register and zero. It writes the result to the **FPSCR** flags. These are normally transferred to the **PSTATE**.{N, Z, C, V} Condition flags by a subsequent VMRS instruction.

It raises an Invalid Operation exception if either operand is any type of NaN.

Depending on settings in the **CPACR**, **NSACR**, and **HCPTR** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

## Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        if half_to_single then
            Elem[Q[d>>1],e,32] = FPConvert(Elem[Din[m],e,16], StandardFPSCRValue());
        else
            Elem[D[d],e,16] = FPConvert(Elem[Qin[m>>1],e,32], StandardFPSCRValue());

```

## F6.1.56 VCVT (between floating-point and integer, Advanced SIMD)

Vector Convert between floating-point and integer converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m+r],e,esize];
            if to_integer then
                result = FPToFixed(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_ZERO);
            else
                result = FixedToFP(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_TIEEVEN);
            Elem[D[d+r],e,esize] = result;
```

## F6.1.57 VCVT (floating-point to integer, floating-point)

Convert floating-point to integer with Round towards Zero converts a value in a register from floating-point to a 32-bit integer, using the Round towards Zero rounding mode, and places the result in a second register.

[VCVT \(between floating-point and fixed-point, floating-point\)](#) describes conversions between floating-point and 16-bit integers.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

## F6.1.59 VCVT (between floating-point and fixed-point, Advanced SIMD)

Vector Convert between floating-point and fixed-point converts each element in a vector from floating-point to fixed-point, or from fixed-point to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

U32	when op = 10, U = 1												
F32	when op = 11, U = x												
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.												
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.												
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.												
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.												

<fbits>      The number of fraction bits in the fixed point number, in the range 1 to 32 for 32-bit elements, or in the range 1 to 16 for 16-bit elements:

- (64 - <fbits>) is encoded in imm6.

An assembler can permit an <fbits> value of 0. This is encoded as floating-point to integer or integer to floating-point instruction, see [VCVT \(between floating-point and integer, Advanced SIMD\)](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m+r],e,esize];
            if to_fixed then
                result = FPToFixed(op1, frac_bits, unsigned, StandardFPSCRValue(),
                                   FPRounding_ZERO);
            else
                result = FixedToFP(op1, frac_bits, unsigned, StandardFPSCRValue(),
                                   FPRounding_TIEEVEN);
            Elem[D[d+r],e,esize] = result;
```

## F6.1.60 VCVT (between floating-point and fixed-point, floating-point)

Convert between floating-point and fixed-point converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

  when '11' esize = 64; m = UInt(M:Vm);
```

### T1

#### Half-precision scalar variant

Applies when size == 01.

VCVTA{<q>}.<dt>.F16 <Sd>, <Sm>

#### Single-precision scalar variant

Applies when size == 10.

VCVTA{<q>}.<dt>.F32 <Sd>, <Sm>

### Double-precision scalar variant

Applies when size == 11.

VCVTA{<q>}.<dt>.F64 <Sd>, <Dm>

### Decode for all variants of this encoding

```
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
rounding = FPDecodeRM(RM); unsigned = (op == '0');
d = UInt(Vd:D);
case size of
    when '01' esize = 16; m = UInt(Vm:M);
    when '10' esize = 32; m = UInt(Vm:M);
    when '11' esize = 64; m = UInt(M:Vm);
if InITBlock() then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the destination, encoded in the "op" field. It can have the following values: <div> U32          when op = 0  S32          when op = 1 </div>
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```
EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
case esize of
    when 16
        S[d] = FPToFixed(S[m]<15:0>, 0, unsigned, FPSCR, rounding);
    when 32
        S[d] = FPToFixed(S[m], 0, unsigned, FPSCR, rounding);
    when 64
        S[d] = FPToFixed(D[m], 0, unsigned, FPSCR, rounding);
```

## F6.1.63 VCVTB

Convert to or from a half-precision value in the bottom half of a single-precision register does one of the following:

- Converts the half-precision value in the bottom half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the bottom half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

                                           StandardFPSCRValue(), rounding);

```

## F6.1.69 VCVTP (floating-point)

Convert floating-point to integer with Round towards +Infinity converts a value in a register from floating-point to a 32-bit integer using the Round towards +Infinity rounding mode, and places the result in a second register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

## F6.1.71 VCVTT

Convert to or from a half-precision value in the top half of a single-precision register does one of the following:

- Converts the half-precision value in the top half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the top half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:D" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:N" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:M" field.

### Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
case esize of
  when 16
    S[d] = Zeros(16) : FPDIV(S[n]<15:0>, S[m]<15:0>, FPSCR);
  when 32
    S[d] = FPDIV(S[n], S[m], FPSCR);
  when 64
    D[d] = FPDIV(D[n], D[m], FPSCR);
```

### F6.1.73 VDUP (general-purpose register)

Duplicate general-purpose register to vector duplicates an element from a general-purpose register into every element of the destination vector.

The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the general-purpose register. There is no distinction between data types.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> . ARM strongly recommends that any VDUP instruction is unconditional, see <a href="#">Conditional execution on page F2-2849</a> .						
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .						
<size>	The data size for the elements of the destination vector. It must be one of: <table> <tr> <td>8</td><td>Encoded as [b, e] = 0b10.</td></tr> <tr> <td>16</td><td>Encoded as [b, e] = 0b01.</td></tr> <tr> <td>32</td><td>Encoded as [b, e] = 0b00.</td></tr> </table>	8	Encoded as [b, e] = 0b10.	16	Encoded as [b, e] = 0b01.	32	Encoded as [b, e] = 0b00.
8	Encoded as [b, e] = 0b10.						
16	Encoded as [b, e] = 0b01.						
32	Encoded as [b, e] = 0b00.						
<Qd>	The destination vector for a quadword operation.						
<Dd>	The destination vector for a doubleword operation.						
<Rt>	The ARM source register.						

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    scalar = R[t]<size-1:0>;
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;

```

## F6.1.74 V DUP (scalar)

Duplicate vector element to vector duplicates a single element of a vector into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see [Advanced SIMD scalars on page F2-2874](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

if Q == '1' && Vd<0> == '1' then UNDEFINED;
case imm4 of
  when 'xxx1'  esize = 8;  elements = 8;  index = UInt(imm4<3:1>);
  when 'xx10'  esize = 16; elements = 4;  index = UInt(imm4<3:2>);
  when 'x100'  esize = 32; elements = 2;  index = UInt(imm4<3>);
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

```

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional.  For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	The data size. It must be one of:  8            Encoded as imm4<0> = '1'. imm4<3:1> encodes the index [x] of the scalar. 16          Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index [x] of the scalar. 32          Encoded as imm4<2:0> = '100'. imm4<3> encodes the index [x] of the scalar.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm[x]>	The scalar. For details of how [x] is encoded, see the description of <size>.

### Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  scalar = Elem[D[m],index,esize];
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = scalar;

```

## F6.1.75 VEOR

Vector Bitwise Exclusive OR performs a bitwise Exclusive OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

#### 64-bit SIMD vector variant

Applies when Q == 0.

VEOR{<c>}{<q>}{.<dt>} {<Dd>}, <Dn>, <Dm>

#### 128-bit SIMD vector variant

Applies when Q == 1.

VEOR{<c>}{<q>}{.<dt>} {<Qd>}, <Qn>, <Qm>

#### Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;  
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

### Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	An optional data type. It is ignored by assemblers, and does not affect the encoding.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] EOR D[m+r];
```

## F6.1.76 VEXT (byte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

The following figure shows the operation of VEXT doubleword operation for  $\text{imm} = 3$ .

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

This instruction is used by the pseudo-instruction **VEXT (multibyte elements)**. The pseudo-instruction is never the preferred disassembly.

<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<imm>	For the 64-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 7, encoded in the "imm4" field.  For the 128-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 15, encoded in the "imm4" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    if quadword_operation then
        Q[d>>1] = (Q[m>>1]:Q[n>>1])<position+127:position>;
    else
        D[d] = (D[m]:D[n])<position+63:position>;
```

## F6.1.77 VEXT (multibyte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector

This instruction is a pseudo-instruction of the **VEXT (byte elements)** instruction. This means that:

- The encodings in this description are named to match the encodings of **VEXT (byte elements)**.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of **VEXT (byte elements)** gives the operational pseudocode for this instruction.

### A1

```

## F6.1.79 VFMS

Vector Fused Multiply Subtract negates the elements of one vector and multiplies them with the corresponding elements of another vector, adds the products to the corresponding elements of the destination vector, and places the results in the destination vector. The instruction does not round the result of the multiply before the addition.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

														op											

### Half-precision scalar variant

Applies when size == 01.

VFNMMS{<c>}{<q>}.F16 <Sd>, <Sn>, <Sm>

### Single-precision scalar variant

Applies when size == 10.

VFNMMS{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

### Double-precision scalar variant

Applies when size == 11.

VFNMMS{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

### Decode for all variants of this encoding

```
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
op1_neg = (op == '1');
case size of
  when '01' esize = 16; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
  when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
  when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

### CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
  case esize of
    when 16
      op16 = if op1_neg then FPNeg(S[n]<15:0>) else S[n]<15:0>;
      S[d] = Zeros(16) : FPMu1Add(FPNeg(S[d]<15:0>), op16, S[m]<15:0>, FPSCR);
    when 32
      op32 = if op1_neg then FPNeg(S[n]) else S[n];
```

```
S[d] = FPMu1Add(FPNeg(S[d]), op32, S[m], FPSCR);  
when 64  
op64 = if op1_neg then FPNeg(D[n]) else D[n];  
D[d] = FPMu1Add(FPNeg(D[d]), op64, D[m], FPSCR);
```

## F6.1.82 VHADD

Vector Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated. For rounded results, see [VRHADD](#).

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

## F6.1.84 VINS

Vector move Insertion. This instruction copies the lower 16 bits of the 32-bit source SIMD&FP register into the upper 16 bits of the 32-bit destination SIMD&FP register, while preserving the values in the remaining bits.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

<c>	For encoding A1, A2 and A3: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional.  For encoding T1, T2 and T3: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values:  8           when size = 00 16          when size = 01 32          when size = 10
<list>	Is a list containing the single 64-bit name of the SIMD&FP register holding the element. The list must be { <Dd>[<index>] }. The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:  <size> == 8           <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field. <size> == 16          <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field. <size> == 32          <index> is 0 or 1, encoded in the "index_align<3>" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2777](#), and the encoding depends on <size>:

<size> == 8            Encoded in the "index\_align<0>" field as 0.  
 <size> == 16          Encoded in the "index\_align<1:0>" field as 0b00.  
 <size> == 32          Encoded in the "index\_align<2:0>" field as 0b000.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 16          <align> is 16, meaning 16-bit alignment, encoded in the  
                          "index\_align<1:0>" field as 0b01.  
 <size> == 32          <align> is 32, meaning 32-bit alignment, encoded in the  
                          "index\_align<2:0>" field as 0b011.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2869](#).

<Rm>            Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d],index] = MemU[address,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
```

## F6.1.86 VLD1 (single element to all lanes)

Load single 1-element structure and replicate to all lanes of one register loads one element from memory into every element of one or two vectors. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
1	1	1	1	0	1	0	0	1	D	1	0	Rn	Vd	1	1	0	0	size	T	a	Rm				

#### Offset variant

Applies when Rm == 1111.

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

#### Post-indexed variant

Applies when Rm == 1101.

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

#### Post-indexed variant

Applies when Rm != 11x1.

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

#### Decode for all variants of this encoding

```
if size == '11' || (size == '00' && a == '1') then UNDEFINED;
ebytes = 1 << UInt(size); regs = if T == '0' then 1 else 2;
alignment = if a == '0' then 1 else ebytes;
d = UInt(D:Vd); n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	10	9	8	7	6	5	4	3	0

### Offset variant

Applies when Rm == 1111.

VLD1{<C>}{<q>}.<size> <list>, [<Rn>{:<align>}]

### Post-indexed variant

Applies when Rm == 1101.

VLD1{<C>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

### Post-indexed variant

Applies when Rm != 11x1.

VLD1{<C>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

### Decode for all variants of this encoding

```
if size == '11' || (size == '00' && a == '1') then UNDEFINED;
ebytes = 1 << UInt(size); regs = if T == '0' then 1 else 2;
alignment = if a == '0' then 1 else ebytes;
d = UInt(D:Vd); n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD1 (single element to all lanes)* on page K1-6110.

### Assembler symbols

<C>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8            when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<list>	Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of: { <Dd>[] } Encoded in the "T" field as 0.

{ <Dd>[], <Dd+1>[] }Encoded in the "T" field as 1.  
The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.  
Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2777](#), and is encoded in the "a" field as 0.  
Whenever <align> is present, the permitted values and encoding depend on <size>:  
<size> == 16                      <align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1.  
<size> == 32                      <align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.  
: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2869](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    bits(64) replicated_element = Replicate(MemU[address,ebytes]);
    for r = 0 to regs-1
        D[d+r] = replicated_element;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
```

## F6.1.87 VLD1 (multiple single elements)

Load multiple single 1-element structures to one, two, three, or four registers loads elements from memory into one, two, three, or four registers, without de-interleaving. Every element of each register is loaded. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

```

### CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD1 (multiple single elements)* on page K1-6110.

Related encodings: See *Advanced SIMD element or structure load/store* on page F3-2922 for the T32 instruction set, or *Advanced SIMD element or structure load/store* on page F4-2997 for the A32 instruction set.

## Assembler symbols

<c> For encoding A1, A2, A3 and A4: see [Standard assembler syntax fields](#) on page F2-2848. This encoding must be unconditional.

For encoding T1, T2, T3 and T4: see [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<size> Is the data size, encoded in the "size" field. It can have the following values:

8	when size = 00
16	when size = 01
32	when size = 10
64	when size = 11

<list> Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

{ <Dd> }	Single register. Selects the A1 and T1 encodings of the instruction.
{ <Dd>, <Dd+1> }	Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.
{ <Dd>, <Dd+1>, <Dd+2> }	Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.
{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }	Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2777](#), and is encoded in the "align" field as 0b00.

Whenever <align> is present, the permitted values are:

64	64-bit alignment, encoded in the "align" field as 0b01.
128	128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.
256	256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2869](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to regs-1
        for e = 0 to elements-1

        else
            R[n] = R[n] + 8*regs;

```

## F6.1.88 VLD2 (single 2-element structure to one lane)

Load single 2-element structure to one lane of two registers loads one 2-element structure from memory into corresponding elements of two registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	4	3	0
1	1	1	1	0	1	0	0	1	D	1	0	Rn	Vd	0	0	0	1	index_align	Rm	size			

#### Offset variant

Applies when Rm == 1111.

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

#### Post-indexed variant

Applies when Rm == 1101.

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

#### Post-indexed variant

Applies when Rm != 11x1.

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

#### Decode for all variants of this encoding

```
if size == '11' then SEE VLD2 (single 2-element structure to all lanes);
ebytes = 1; index = UInt(index_align<3:1>); inc = 1;
alignment = if index_align<0> == '0' then 1 else 2;

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD2 (single 2-element structure to one lane)* on page K1-6110.

### Assembler symbols

<C>	For encoding A1, A2 and A3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848. This encoding must be unconditional. For encoding T1, T2 and T3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848.								
<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.								
<size>	Is the data size, encoded in the "size" field. It can have the following values: <table> <tr> <td>8</td><td>when size = 00</td></tr> <tr> <td>16</td><td>when size = 01</td></tr> <tr> <td>32</td><td>when size = 10</td></tr> </table>	8	when size = 00	16	when size = 01	32	when size = 10		
8	when size = 00								
16	when size = 01								
32	when size = 10								
<list>	Is a list containing the 64-bit names of the two SIMD&FP registers holding the element. The list must be one of: <table> <tr> <td>{ &lt;Dd&gt;[&lt;index&gt;], &lt;Dd+1&gt;[&lt;index&gt;] }</td><td>Single-spaced registers, encoded as "spacing" = 0.</td></tr> <tr> <td>{ &lt;Dd&gt;[&lt;index&gt;], &lt;Dd+2&gt;[&lt;index&gt;] }</td><td>Double-spaced registers, encoded as "spacing" = 1. Not permitted when &lt;size&gt; == 8.</td></tr> </table> The encoding of "spacing" depends on <size>: <table> <tr> <td>&lt;size&gt; == 16</td><td>"spacing" is encoded in the "index_align&lt;1&gt;" field.</td></tr> <tr> <td>&lt;size&gt; == 32</td><td>"spacing" is encoded in the "index_align&lt;2&gt;" field.</td></tr> </table> The register <Dd> is encoded in the "D:Vd" field.	{ <Dd>[<index>], <Dd+1>[<index>] }	Single-spaced registers, encoded as "spacing" = 0.	{ <Dd>[<index>], <Dd+2>[<index>] }	Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.	<size> == 16	"spacing" is encoded in the "index_align<1>" field.	<size> == 32	"spacing" is encoded in the "index_align<2>" field.
{ <Dd>[<index>], <Dd+1>[<index>] }	Single-spaced registers, encoded as "spacing" = 0.								
{ <Dd>[<index>], <Dd+2>[<index>] }	Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.								
<size> == 16	"spacing" is encoded in the "index_align<1>" field.								
<size> == 32	"spacing" is encoded in the "index_align<2>" field.								

	The permitted values and encoding of <index> depend on <size>:
<size> == 8	<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16	<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32	<index> is 0 or 1, encoded in the "index_align<3>" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access on page E2-2777</a> , and the encoding depends on <size>: <size> == 8            Encoded in the "index_align<0>" field as 0. <size> == 16          Encoded in the "index_align<0>" field as 0. <size> == 32          Encoded in the "index_align<1:0>" field as 0b00. Whenever <align> is present, the permitted values and encoding depend on <size>: <size> == 8            <align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1. <size> == 16          <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1. <size> == 32          <align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see <a href="#">The Advanced SIMD addressing mode on page F2-2869</a> .
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d], index] = MemU[address, ebytes];
    Elem[D[d2], index] = MemU[address+ebytes, ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;

```

## F6.1.89 VLD2 (single 2-element structure to all lanes)

Load single 2-element structure and replicate to all lanes of two registers loads one 2-element structure from memory into all lanes of two registers. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### CONSTRAINED UNPREDICTABLE behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD2 (single 2-element structure to all lanes)* on page K1-6111.

### Assembler symbols

<C>	For encoding A1: see <a href="#">Standard assembler syntax fields</a> on page F2-2848. This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8           when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<list>	Is a list containing the 64-bit names of two SIMD&FP registers. The list must be one of: { <Dd>[], <Dd+1>[] } Single-spaced registers, encoded in the "T" field as 0.

- { <Dd>[], <Dd+2>[] } Double-spaced registers, encoded in the "T" field as 1.  
The register <Dd> is encoded in the "D:Vd" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment.  
Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2777](#), and is encoded in the "a" field as 0.  
Whenever <align> is present, the permitted values and encoding depend on <size>:  

<size> == 8	<align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1.
<size> == 16	<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.
<size> == 32	<align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2869](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;

```

## F6.1.90 VLD2 (multiple 2-element structures)

Load multiple 2-element structures to two or four registers loads multiple 2-element structures from memory into two or four registers, with de-interleaving. For more information, see [Element and structure load/store instructions on page F1-2829](#). Every element of each register is loaded. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

#### CONSTRAINED UNPREDICTABLE behavior

If d2+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

## A2

d = UInt(D:Vd); d2 = d + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d2+regs > 32 then UNPREDICTABLE;
```

## CONSTRAINED UNPREDICTABLE behavior

If  $d2 + \text{regs} > 32$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD2 (multiple 2-element structures)* on page K1-6110.

Related encodings: See *Advanced SIMD element or structure load/store* on page F3-2922 for the T32 instruction set, or *Advanced SIMD element or structure load/store* on page F4-2997 for the A32 instruction set.

## Assembler symbols

<c>	For encoding A1 and A2: see <a href="#">Standard assembler syntax fields</a> on page F2-2848. This encoding must be unconditional.  For encoding T1 and T2: see <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8           when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<list>	Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of: { <Dd>, <Dd+1> }      Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1000. { <Dd>, <Dd+2> }      Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1001. { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Three single-spaced registers. Selects the A2 and T2 encodings of the instruction. The register <Dd> is encoded in the "D:Vd" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment.  Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access</a> on page E2-2777, and is encoded in the "align" field as 0b00.  Whenever <align> is present, the permitted values are: 64           64-bit alignment, encoded in the "align" field as 0b01. 128          128-bit alignment, encoded in the "align" field as 0b10. 256          256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2869](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r], e] = MemU[address, ebytes];
            Elem[D[d2+r], e] = MemU[address+ebytes, ebytes];
            address = address + 2*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 16*regs;
```

## F6.1.91 VLD3 (single 3-element structure to one lane)

Load single 3-element structure to one lane of three registers loads one 3-element structure from memory into corresponding elements of three registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD3 (single 3-element structure to one lane)* on page K1-6111.

### Assembler symbols

<c>	For encoding A1, A2 and A3: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1, T2 and T3: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8           when size = 00 16          when size = 01 32          when size = 10
<list>	Is a list containing the 64-bit names of the three SIMD&FP registers holding the element. The list must be one of: { <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] } Single-spaced registers, encoded as "spacing" = 0. { <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8. The encoding of "spacing" depends on <size>: <size> == 8           "spacing" is encoded in the "index_align<0>" field. <size> == 16         "spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0. <size> == 32         "spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8                    <index> is in the range 0 to 7, encoded in the "index\_align<3:1>" field.

<size> == 16                  <index> is in the range 0 to 3, encoded in the "index\_align<3:2>" field.

<size> == 32                  <index> is 0 or 1, encoded in the "index\_align<3>" field.

<Rn>                    Is the general-purpose base register, encoded in the "Rn" field.

<Rm>                    Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

### Alignment

Standard alignment rules apply, see [Alignment support on page B2-102](#).

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2],index] = MemU[address+ebytes,ebytes];
    Elem[D[d3],index] = MemU[address+2*ebytes,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 3*ebytes;
```

### Offset variant

Applies when Rm == 1111.

VLD3{<C>}{<q>}.<size> <list>, [<Rn>]

### Post-indexed variant

Applies when Rm == 1101.

VLD3{<C>}{<q>}.<size> <list>, [<Rn>]!

### Post-indexed variant

Applies when Rm != 11x1.

VLD3{<C>}{<q>}.<size> <list>, [<Rn>], <Rm>

### Decode for all variants of this encoding

```
if size == '11' || a == '1' then UNDEFINED;
ebytes = 1 << UInt(size);
inc = if T == '0' then 1 else 2;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD3 (single 3-element structure to all lanes)* on page K1-6111.

### Assembler symbols

<C>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8           when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<list>	Is a list containing the 64-bit names of three SIMD&FP registers. The list must be one of: { <Dd>[], <Dd+1>[], <Dd+2>[] } Single-spaced registers, encoded in the "T" field as 0.

{ <Dd>[], <Dd+2>[], <Dd+4>[] }

Double-spaced registers, encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

### Alignment

Standard alignment rules apply, see [Alignment support on page B2-102](#).

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 3*ebytes;
```

### F6.1.93 VLD3 (multiple 3-element structures)

Load multiple 3-element structures to three registers loads multiple 3-element structures from memory into three registers, with de-interleaving. For more information, see [Element and structure load/store instructions on page F1-2829](#). Every element of each register is loaded. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
1	1	1	1	0	1	0	0	0	D	1	0	Rn	Vd	0	1	0	x	size	align	Rm			

type

#### Offset variant

Applies when Rm == 1111.

VLD3{<C>}{<q>}.<size> <list>, [<Rn>{:<align>}]

#### Post-indexed variant

Applies when Rm == 1101.

VLD3{<C>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

#### Post-indexed variant

Applies when Rm != 11x1.

VLD3{<C>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

#### Decode for all variants of this encoding

```

case type of
  when '0100'
    inc = 1;
  when '0101'
    inc = 2;
  otherwise
    SEE "Related encodings";
if size == '11' || align<1> == '1' then UNDEFINED;
alignment = if align<0> == '0' then 1 else 8;
ebytes = 1 << UInt(size); elements = 8 DIV ebytes;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;

```

#### CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

```

### CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD3 (multiple 3-element structures)* on page K1-6111.

Related encodings: See *Advanced SIMD element or structure load/store* on page F3-2922 for the T32 instruction set, or *Advanced SIMD element or structure load/store* on page F4-2997 for the A32 instruction set.

## Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8           when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<list>	Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of: { <Dd>, <Dd+1>, <Dd+2> } Single-spaced registers, encoded in the "type" field as 0b0100. { <Dd>, <Dd+2>, <Dd+4> } Double-spaced registers, encoded in the "type" field as 0b0101. The register <Dd> is encoded in the "D:Vd" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access on page E2-2777</a> , and is encoded in the "align" field as 0b00. Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b01. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see <a href="#">The Advanced SIMD addressing mode on page F2-2869</a> .
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about <Rn>, !, and <Rm>, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        Elem[D[d], e] = MemU[address,ebytes];
        Elem[D[d2],e] = MemU[address+ebytes,ebytes];
        Elem[D[d3],e] = MemU[address+2*ebytes,ebytes];
        address = address + 3*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 24;

```

## F6.1.94 VLD4 (single 4-element structure to one lane)

Load single 4-element structure to one lane of four registers loads one 4-element structure from memory into corresponding elements of four registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD4 (single 4-element structure to one lane)* on page K1-6111.

### Assembler symbols

<C>	For encoding A1, A2 and A3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848. This encoding must be unconditional. For encoding T1, T2 and T3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<size>	Is the data size, encoded in the "size" field. It can have the following values: <div> 8            when size = 00  16          when size = 01  32          when size = 10 </div>
<list>	Is a list containing the 64-bit names of the four SIMD&FP registers holding the element. The list must be one of: <div> { &lt;Dd&gt;[&lt;index&gt;], &lt;Dd+1&gt;[&lt;index&gt;], &lt;Dd+2&gt;[&lt;index&gt;], &lt;Dd+3&gt;[&lt;index&gt;] }  Single-spaced registers, encoded as "spacing" = 0.  { &lt;Dd&gt;[&lt;index&gt;], &lt;Dd+2&gt;[&lt;index&gt;], &lt;Dd+4&gt;[&lt;index&gt;], &lt;Dd+6&gt;[&lt;index&gt;] }  Double-spaced registers, encoded as "spacing" = 1. Not permitted when &lt;size&gt; == 8. </div> The encoding of "spacing" depends on <size>: <size> == 16            "spacing" is encoded in the "index_align<1>" field. <size> == 32            "spacing" is encoded in the "index_align<2>" field. The register <Dd> is encoded in the "D:Vd" field.

	The permitted values and encoding of <index> depend on <size>:
<size> == 8	<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16	<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32	<index> is 0 or 1, encoded in the "index_align<3>" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access on page E2-2777</a> , and the encoding depends on <size>: <size> == 8            Encoded in the "index_align<0>" field as 0. <size> == 16          Encoded in the "index_align<0>" field as 0. <size> == 32          Encoded in the "index_align<1:0>" field as 0b00. Whenever <align> is present, the permitted values and encoding depend on <size>: <size> == 8            <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1. <size> == 16          <align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1. <size> == 32          <align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see <a href="#">The Advanced SIMD addressing mode on page F2-2869</a> .
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2],index] = MemU[address+ebytes,ebytes];
    Elem[D[d3],index] = MemU[address+2*ebytes,ebytes];
    Elem[D[d4],index] = MemU[address+3*ebytes,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;

```

## F6.1.95 VLD4 (single 4-element structure to all lanes)

Load single 4-element structure and replicate to all lanes of four registers loads one 4-element structure from memory into all lanes of four registers. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Decode for all variants of this encoding

```

if size == '11' && a == '0' then UNDEFINED;
if size == '11' then
    ebytes = 4; alignment = 16;
else
    ebytes = 1 << UInt(size);
    if size == '10' then
        alignment = if a == '0' then 1 else 8;
    else
        alignment = if a == '0' then 1 else 4*ebytes;
inc = if T == '0' then 1 else 2;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; d4 = d3 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;

```

### CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD4 (single 4-element structure to all lanes)* on page K1-6112.

### Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8            when size = 00 16           when size = 01 32           when size = 1x
<list>	Is a list containing the 64-bit names of four SIMD&FP registers. The list must be one of: { <Dd>[], <Dd+1>[], <Dd+2>[], <Dd+3>[] } Single-spaced registers, encoded in the "T" field as 0. { <Dd>[], <Dd+2>[], <Dd+4>[], <Dd+6>[] } Double-spaced registers, encoded in the "T" field as 1. The register <Dd> is encoded in the "D:Vd" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access on page E2-2777</a> , and is encoded in the "a" field as 0. Whenever <align> is present, the permitted values and encoding depend on <size>: <size> == 8            <align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1. <size> == 16           <align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1. <size> == 32           <align> can be 64 or 128. 64-bit alignment is encoded in the "a:size<0>" field as 0b10, and 128-bit alignment is encoded in the "a:size<0>" field as 0b11. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see <a href="#">The Advanced SIMD addressing mode on page F2-2869</a> .
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
    D[d4] = Replicate(MemU[address+3*ebytes,ebytes]);
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;

```

## F6.1.96 VLD4 (multiple 4-element structures)

Load multiple 4-element structures to four registers loads multiple 4-element structures from memory into four registers, with de-interleaving. For more information, see [Element and structure load/store instructions on page F1-2829](#). Every element of each register is loaded. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST4 (multiple 4-element structures)* on page K1-6113.

Related encodings: See [Advanced SIMD element or structure load/store on page F3-2922](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store on page F4-2997](#) for the A32 instruction set.

## Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8           when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<list>	Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of: { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Single-spaced registers, encoded in the "type" field as 0b0000. { <Dd>, <Dd+2>, <Dd+4>, <Dd+6> } Double-spaced registers, encoded in the "type" field as 0b0001. The register <Dd> is encoded in the "D:Vd" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access on page E2-2777</a> , and is encoded in the "align" field as 0b00. Whenever <align> is present, the permitted values are: 64           64-bit alignment, encoded in the "align" field as 0b01. 128          128-bit alignment, encoded in the "align" field as 0b10. 256          256-bit alignment, encoded in the "align" field as 0b11. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see <a href="#">The Advanced SIMD addressing mode on page F2-2869</a> .
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        Elem[D[d], e] = MemU[address,ebytes];
        Elem[D[d2],e] = MemU[address+ebytes,ebytes];
        Elem[D[d3],e] = MemU[address+2*ebytes,ebytes];
        Elem[D[d4],e] = MemU[address+3*ebytes,ebytes];
        address = address + 4*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 32;

```

## F6.1.97 VLDM, VLDMDB, VLDMIA

Load Multiple SIMD&FP registers loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

This instruction is used by the alias VPOP. See [Alias conditions on page F6-3938](#) for details of when each alias is preferred.

### A1

#### Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

VLDMDB{<c>}{<q>}{<size>} <Rn>!, <dreglist>

#### Increment After variant

Applies when P == 0 && U == 1.

VLDM{<c>}{<q>}{<size>} <Rn>{!}, <dreglist>  
VLDMIA{<c>}{<q>}{<size>} <Rn>{!}, <dreglist>

#### Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VLDR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FLDM*X".

if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If `(d+regs) > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLDM* on page K1-6112.

Related encodings: See *Advanced SIMD and floating-point 64-bit move* on page F3-2894 for the T32 instruction set, or *Advanced SIMD and floating-point 64-bit move* on page F4-2973 for the A32 instruction set.

### Alias conditions

Alias	is preferred when
VPOP	P == '0' && U == '1' && W == '1' && Rn == '1101'

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<size>	An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
!	Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
<sreglist>	Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
<dreglist>	Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4]; address = address+4;
        else
            word1 = MemA[address,4]; word2 = MemA[address+4,4]; address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

## F6.1.98 VLDR (immediate)

Load SIMD&FP register (immediate) loads a single register from the Advanced SIMD and floating-point register file, using an address from a general-purpose register, with an optional offset.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
.64	Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
.32	Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>
<imm>	For encoding A1 or T1: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2.  For encoding A1, T1: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
```

```
case esize of
  when 16
    S[d] = Zeros(16) : MemA[address,2];
  when 32
    S[d] = MemA[address,4];
  when 64
    word1 = MemA[address,4]; word2 = MemA[address+4,4];
    // Combine the word-aligned words in the correct order for current endianness.
    D[d] = if BigEndian() then word1:word2 else word2:word1;
```

## F6.1.99 VLDR (literal)

Load SIMD&FP register (literal) loads a single register from the Advanced SIMD and floating-point register file, using an address from the PC value and an immediate offset.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
.64	Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
.32	Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<label>	The label of the literal data item to be loaded. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020.  If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:  -           when U = 0

+                   when U = 1

<imm>           For encoding A1 or T1: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2.

                  For encoding A1, T1: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2809](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    case esize of
        when 16
            S[d] = Zeros(16) : MemA[address,2];
        when 32
            S[d] = MemA[address,4];
        when 64
            word1 = MemA[address,4]; word2 = MemA[address+4,4];
            // Combine the word-aligned words in the correct order for current endianness.
            D[d] = if BigEndian() then word1:word2 else word2:word1;
```

## F6.1.100 VMAX (floating-point)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

#### 64-bit SIMD vector variant

```

### T1

#### 64-bit SIMD vector variant

Applies when Q == 0.

VMAX{<C>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

#### 128-bit SIMD vector variant

Applies when Q == 1.

VMAX{<C>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

#### Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
if sz == '1' && InITBlock() then UNPREDICTABLE;

```

```
maximum = (op == '0');
case sz of
    when '0' esize = 32; elements = 2;
    when '1' esize = 16; elements = 4;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

### CONSTRAINED UNPREDICTABLE behavior

If `sz == '1'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: F32          when sz = 0 F16          when sz = 1
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

### Floating-point maximum and minimum

- $\max(+0.0, -0.0) = +0.0$
- If any input is a NaN, the corresponding result element is the default NaN.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize]; op2 = Elem[D[m+r],e,esize];
            if maximum then
                Elem[D[d+r],e,esize] = FPMax(op1, op2, StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
```

## F6.1.101 VMAX (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

            result = if maximum then Max(op1,op2) else Min(op1,op2);
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

## F6.1.102 VMAXNM

This instruction determines the floating-point maximum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMAX.

This instruction is not conditional.

```

### F6.1.103 VMIN (floating-point)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### CONSTRAINED UNPREDICTABLE behavior

If `sz == '1'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: F32          when sz = 0 F16          when sz = 1
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

### Floating-point minimum

- $\min(+0.0, -0.0) = -0.0$
- If any input is a NaN, the corresponding result element is the default NaN.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize]; op2 = Elem[D[m+r],e,esize];
            if maximum then
                Elem[D[d+r],e,esize] = FPMax(op1, op2, StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = FPMIn(op1, op2, StandardFPSCRValue());
```

### F6.1.104 VMIN (integer)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

## F6.1.105 VMINNM

This instruction determines the floating point minimum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMIN.

This instruction is not conditional.

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values: S16           when U = 0, size = 01 S32           when U = 0, size = 10 U16           when U = 1, size = 01 U32           when U = 1, size = 10
<Qd>	Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm[x]>	Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16 or U16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is S32 or U32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize]; op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize]; op1val = Int(op1, unsigned);
            if floating_point then
                fp_addend = if add then FPMul(op1,op2,StandardFPSCRValue()) else
                    FPNeg(FPMul(op1,op2,StandardFPSCRValue()));
                Elem[D[d+r],e,esize] = FPAdd(Elem[Din[d+r],e,esize], fp_addend, StandardFPSCRValue());
            else
                addend = if add then op1val*op2val else -op1val*op2val;
                if long_destination then
                    Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + addend;
                else
                    Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;

```

## F6.1.111 VMLS (floating-point)

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

### ———— Note ————

ARM recommends that software does not use the VMLS instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

#### 128-bit SIMD vector variant

Applies when Q == 1.

VMLS{<C>}{<q>}.<dt> <Qd>, <Qn>, <Dm[x]>

### Decode for all variants of this encoding

```
if size == '11' then SEE "Related encodings";
if size == '00' || (F == '1' && size == '01' && !HaveFP16Ext()) then UNDEFINED;
if F == '1' && size == '01' && InITBlock() then UNPREDICTABLE;
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1') then UNDEFINED;
unsigned = FALSE; // "Don't care" value: TRUE produces same functionality
add = (op == '0'); floating_point = (F == '1'); long_destination = FALSE;
d = UInt(D:Vd); n = UInt(N:Vn); regs = if Q == '0' then 1 else 2;
if size == '01' then esize = 16; elements = 4; m = UInt(Vm<2:0>); index = UInt(M:Vm<3>);
if size == '10' then esize = 32; elements = 2; m = UInt(Vm); index = UInt(M);
```

### CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2904](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2985](#) for the A32 instruction set.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the scalar and the elements of the operand vector, encoded in the "F:size" field. It can have the following values: I16          when F = 0, size = 01 I32          when F = 0, size = 10 F16          when F = 1, size = 01 F32          when F = 1, size = 10
<Qd>	Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Dd>	Is the 64-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm[x]>	Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is I16 or F16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is I32 or F32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize]; op2val = Int(op2, unsigned);
    for r = 0 to regs-1
```

```

for e = 0 to elements-1

### Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2904](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2985](#) for the A32 instruction set.

### Assembler symbols

- <C> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.
- For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).
- <q> See [Standard assembler syntax fields on page F2-2848](#).

<type>	The data type for the elements of the operands. It must be one of:
S	Optional in encoding T1/A1. Encoded as U = 0 in encoding T2/A2.
U	Optional in encoding T1/A1. Encoded as U = 1 in encoding T2/A2.
I	Available only in encoding T1/A1.
<size>	The data size for the elements of the operands. It must be one of:
8	Encoded as size = 0b00.
16	Encoded as size = 0b01.
32	Encoded as size = 0b10.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            product = Int(Elem[Din[n+r],e,esize],unsigned) * Int(Elem[Din[m+r],e,esize],unsigned);
            addend = if add then product else -product;
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + addend;
            else
                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;

```

## F6.1.115 VMLSL (by scalar)

Vector Multiply Subtract Long multiplies elements of a vector by a scalar, and subtracts the products from corresponding elements of the destination vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see [Advanced SIMD scalars on page F2-2874](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

## Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2904](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2985](#) for the A32 instruction set.

## Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values: S16          when U = 0, size = 01 S32          when U = 0, size = 10 U16          when U = 1, size = 01 U32          when U = 1, size = 10
<Qd>	Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm[x]>	Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16 or U16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is S32 or U32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize]; op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize]; op1val = Int(op1, unsigned);
            if floating_point then
                fp_addend = if add then FPMul(op1,op2,StandardFPSCRValue()) else
                    FPNeg(FPMul(op1,op2,StandardFPSCRValue()));
                Elem[D[d+r],e,esize] = FPAdd(Elem[Din[d+r],e,esize], fp_addend, StandardFPSCRValue());
            else
                addend = if add then op1val*op2val else -op1val*op2val;
                if long_destination then

if t == 15 || t2 == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13  
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `to_arm_registers` && `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VMOV (between two general-purpose registers and a doubleword floating-point register)* on page K1-6112.

### Assembler symbols

<Dm>	Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "M:Vm" field.
<Rt2>	Is the first general-purpose register that <Dm>[63:32] will be transferred to or from, encoded in the "Rt" field.
<Rt>	Is the first general-purpose register that <Dm>[31:0] will be transferred to or from, encoded in the "Rt" field.
<C>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .

### Operation for all encodings

```
if ConditionPassed() then  
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);  
    if to_arm_registers then  
        R[t] = D[m]<31:0>;  
        R[t2] = D[m]<63:32>;  
    else  
        D[m]<31:0> = R[t];  
        D[m]<63:32> = R[t2];
```

## F6.1.117 VMOV (between general-purpose register and half-precision)

Copy 16 bits of a general-purpose register to or from a 32-bit SIMD&FP register. This instruction transfers the value held in the bottom 16 bits of a 32-bit SIMD&FP register to the bottom 16 bits of a general-purpose register, or the value held in the bottom 16 bits of a general-purpose register to the bottom 16 bits of a 32-bit SIMD&FP register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
single_register = (size != '11'); advsimd = FALSE;
bits(16) imm16;
bits(32) imm32;
bits(64) imm64;
case size of
  when '01' d = UInt(Vd:D); imm16 = VFPEExpandImm(imm4H:imm4L); imm32 = Zeros(16) : imm16;
  when '10' d = UInt(Vd:D); imm32 = VFPEExpandImm(imm4H:imm4L);
  when '11' d = UInt(D:Vd); imm64 = VFPEExpandImm(imm4H:imm4L); regs = 1;

```

### CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

        for r = 0 to regs-1
            D[d+r] = D[m+r];
```

## F6.1.120 VMOV (register, SIMD)

Copy between SIMD registers copies the contents of one SIMD register to another

This instruction is an alias of the [VORR \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VORR \(register\)](#).
- The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

### A1

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
1	1	1	1	0	0	1	0	0	D	1	0	Vn	Vd		0	0	0	1	N	Q	M	1	Vm		

#### 64-bit SIMD vector variant

Applies when Q == 0.

VMOV{<C>}{<q>}{.dt} <Dd>, <Dm>

is equivalent to

VORR{<C>}{<q>}{.dt} <Dd>, <Dm>, <Dm>

and is the preferred disassembly when N:Vn == M:Vm.

#### 128-bit SIMD vector variant

Applies when Q == 1.

VMOV{<C>}{<q>}{.dt} <Qd>, <Qm>

is equivalent to

VORR{<C>}{<q>}{.dt} <Qd>, <Qm>, <Qm>

and is the preferred disassembly when N:Vn == M:Vm.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	10	9	8	7	6	5	4	3	0
1	1	1	0	1	1	1	1	0	D	1	0	Vn		Vd		0	0	0	1	N	Q	M	1		Vm

#### 64-bit SIMD vector variant

Applies when Q == 0.

VMOV{<C>}{<q>}{.dt} <Dd>, <Dm>

is equivalent to

VORR{<C>}{<q>}{.dt} <Dd>, <Dm>, <Dm>

and is the preferred disassembly when N:Vn == M:Vm.

#### 128-bit SIMD vector variant

Applies when Q == 1.

VMOV{<C>}{<q>}{.dt} <Qd>, <Qm>

is equivalent to

$VORR\{\langle c \rangle\}\{\langle q \rangle\}\{.\langle dt \rangle\} \langle Qd \rangle, \langle Qm \rangle, \langle Qm \rangle$

and is the preferred disassembly when  $N:Vn == M:Vm$ .

### Assembler symbols

$\langle c \rangle$	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
$\langle q \rangle$	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
$\langle dt \rangle$	An optional data type. $\langle dt \rangle$ must not be F64, but it is otherwise ignored.
$\langle Qd \rangle$	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as $\langle Qd \rangle * 2$ .
$\langle Qm \rangle$	Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as $\langle Qm \rangle * 2$ .
$\langle Dd \rangle$	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
$\langle Dm \rangle$	Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

### Operation for all encodings

The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

## F6.1.121 VMOV (general-purpose register to scalar)

Copy a general-purpose register to a vector element copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see [Advanced SIMD scalars on page F2-2874](#).

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

```
to_arm_register = (op == '1'); t = UInt(Rt); n = UInt(Vn:N);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler symbols

- <Rt> Is the general-purpose register that <Sn> will be transferred to or from, encoded in the "Rt" field.
- <Sn> Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Vn:N" field.
- <C> See [Standard assembler syntax fields on page F2-2848](#).
- <q> See [Standard assembler syntax fields on page F2-2848](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if to_arm_register then
        R[t] = S[n];
    else
        S[n] = R[t];
```

### F6.1.123 VMOV (scalar to general-purpose register)

Copy a vector element to a general-purpose register with sign or zero extension copies a byte, halfword, or word from an Advanced SIMD scalar to a general-purpose register. Bytes and halfwords can be either zero-extended or sign-extended.

On a Floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see [Advanced SIMD scalars on page F2-2874](#).

Depending on settings in the CPACR, NSACR, HCPTR, and FPExc registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

    EncodingSpecificOperations(); CheckAdvSIMDorVFPEntered(TRUE, advsimd);
    if unsigned then
        R[t] = ZeroExtend(Elm[D[n],index,esize], 32);
    else
        R[t] = SignExtend(Elm[D[n],index,esize], 32);

```

## F6.1.124 VMOV (between two general-purpose registers and two single-precision registers)

Copy two general-purpose registers to a pair of 32-bit SIMD&FP registers transfers the contents of two consecutively numbered single-precision Floating-point registers to two general-purpose registers, or the contents of two general-purpose registers to a pair of single-precision Floating-point registers. The general-purpose registers do not have to be contiguous.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
!=1111		1	1	0	0	0	1	0	op	Rt2		Rt		1	0	1	0	0	0	M	1	Vm	
cond																							

#### From general-purpose registers variant

Applies when op == 0.

VMOV{<c>}{<q>} <Sm>, <Sm1>, <Rt>, <Rt2>

#### To general-purpose registers variant

Applies when op == 1.

VMOV{<c>}{<q>} <Rt>, <Rt2>, <Sm>, <Sm1>

#### Decode for all variants of this encoding

```
to_arm_registers = (op == '1'); t = UInt(Rt); t2 = UInt(Rt2); m = UInt(Vm:M);
if t == 15 || t2 == 15 || m == 31 then UNPREDICTABLE;
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If to\_arm\_registers && t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

If m == 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	10	9	8	7	6	5	4	3	0
1	1	1	0	1	1	0	0	0	1	0	op	Rt2	Rt	1	0	1	0	0	0	M	1	Vm			

### From general-purpose registers variant

Applies when `op == 0`.

`VMOV{<c>}{<q>} <Sm>, <Sm1>, <Rt>, <Rt2>`

### To general-purpose registers variant

Applies when `op == 1`.

`VMOV{<c>}{<q>} <Rt>, <Rt2>, <Sm>, <Sm1>`

### Decode for all variants of this encoding

```
to_arm_registers = (op == '1'); t = UInt(Rt); t2 = UInt(Rt2); m = UInt(Vm:M);
if t == 15 || t2 == 15 || m == 31 then UNPREDICTABLE;
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `to_arm_registers && t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

If `m == 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VMOV (between two general-purpose registers and two single-precision registers)* on page K1-6112.

### Assembler symbols

<code>&lt;Rt2&gt;</code>	Is the second general-purpose register that <code>&lt;Sm1&gt;</code> will be transferred to or from, encoded in the "Rt" field.
<code>&lt;Rt&gt;</code>	Is the first general-purpose register that <code>&lt;Sm&gt;</code> will be transferred to or from, encoded in the "Rt" field.
<code>&lt;Sm1&gt;</code>	Is the 32-bit name of the second SIMD&FP register to be transferred. This is the next SIMD&FP register after <code>&lt;Sm&gt;</code> .
<code>&lt;Sm&gt;</code>	Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the "Vm:M" field.
<code>&lt;c&gt;</code>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<code>&lt;q&gt;</code>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
if to_arm_registers then
```

```
    R[t] = S[m];  
    R[t2] = S[m+1];  
else  
    S[m] = R[t];  
    S[m+1] = R[t2];
```

## F6.1.125 VMOVL

Vector Move Long takes each element in a doubleword vector, sign or zero-extends them to twice their original length, and places the results in a quadword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2912](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2994](#) for the A32 instruction set.

### Assembler symbols

<C> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<dt>	Is the data type for the elements of the operand, encoded in the "U:imm3H" field. It can have the following values: <div> <div>S8           when U = 0, imm3H = 001</div> <div>S16          when U = 0, imm3H = 010</div> <div>S32          when U = 0, imm3H = 100</div> <div>U8           when U = 1, imm3H = 001</div> <div>U16          when U = 1, imm3H = 010</div> <div>U32          when U = 1, imm3H = 100</div> </div>
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned);
        Elem[Q[d>1],e,2*esize] = result<2*esize-1:0>;

```

## F6.1.126 VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

This instruction is used by the pseudo-instructions VRSHRN (zero) and VSHRN (zero). The pseudo-instruction is never the preferred disassembly.

### T1 variant

VMOVX{<q>}.F16 <Sd>, <Sm>

#### Decode for this encoding

```
if !HaveFP16Ext() then UNDEFINED;
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
if InITBlock() then UNPREDICTABLE;
d = UInt(Vd:D); m = UInt(Vm:M);
```

#### CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<q> See [Standard assembler syntax fields on page F2-2848](#).

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    S[d] = Zeros(16) : S[m]<31:16>;
```

## F6.1.128 VMRS

Move SIMD&FP Special register to general-purpose register moves the value of an Advanced SIMD and floating-point System register to a general-purpose register. When the specified System register is the **FPSCR**, a form of the instruction transfers the **FPSCR**.{N, Z, C, V} condition flags to the **APSR**.{N, Z, C, V} condition flags.

Depending on settings in the **CPACR**, **NSACR**, **HCPT**, and **FPEXC** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

When these settings permit the execution of floating-point and Advanced SIMD instructions, if the specified floating-point System register is not the **FPSCR**, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when **HCR.TID0** is set to 1, any VMRS access to **FPSID** from a Non-secure EL1 mode that would be permitted if **HCR.TID0** was set to 0 generates a Hyp Trap exception. For more information, see [ID group 0, Primary device identification registers on page G1-4435](#).

For simplicity, the VMRS pseudocode does not show the possible trap to Hyp mode.

### A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	1	1	reg	Rt	1	0	1	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)	(0)
cond																									

#### A1 variant

VMRS{<c>}{<q>} <Rt>, <spec\_reg>

#### Decode for this encoding

```
t = UInt(Rt);
if !(reg IN {'000x', '0101', '011x', '1000'}) then UNPREDICTABLE;
if t == 15 && reg != '0001' then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

#### CONSTRAINED UNPREDICTABLE behavior

If !(reg IN {'000x', '0101', '011x', '1000'}), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the **APSR**.{N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	10	9	8	7	6	5	4	3	2	1	0

#### T1 variant

VMRS{<c>}{<q>} <Rt>, <spec\_reg>

### Decode for this encoding

```
t = UInt(Rt);
if !(reg IN {'000x', '0101', '011x', '1000'}) then UNPREDICTABLE;
if t == 15 && reg != '0001' then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### CONSTRAINED UNPREDICTABLE behavior

If !(reg IN {'000x', '0101', '011x', '1000'}), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the [APSR](#).{N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Rt>	Is the general-purpose destination register, encoded in the "Rt" field. Is one of: R0-R14      General-purpose register. APSR_nzcv   Permitted only when <spec_reg> is FPSCR. Encoded as 0b1111. The instruction transfers the <a href="#">FPSCR</a> .{N, Z, C, V} condition flags to the <a href="#">APSR</a> .{N, Z, C, V} condition flags.
<spec_reg>	Is the source Advanced SIMD and floating-point System register, encoded in the "reg" field. It can have the following values: FPSID                  when reg = 0000 FPSCR                  when reg = 0001 MVFR2                  when reg = 0101 MVFR1                  when reg = 0110 MVFR0                  when reg = 0111 FPEXC                  when reg = 1000 The following encodings are UNPREDICTABLE: <ul style="list-style-type: none"> <li>• reg = 001x.</li> <li>• reg = 0100.</li> <li>• reg = 1001.</li> <li>• reg = 101x.</li> <li>• reg = 11xx.</li> </ul>

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
if reg == '0001' then                      // FPSCR
    CheckVFPEnabled(TRUE);
if t == 15 then
    PSTATE.<N,Z,C,V> = FPSR.<N,Z,C,V>;
```

```
else
    R[t] = FPSCR;
elseif PSTATE.EL == EL0 then

else
    CheckVFPEnabled(FALSE); // Non-FPSCR registers are not affected by FPEXC.EN
    case reg of
        // Pseudocode does not consider possible HCR.TIDn Hyp Traps of Non-secure register reads
        when '0000' R[t] = FPSID;
        when '0101' R[t] = MVFR2;
        when '0110' R[t] = MVFR1;
        when '0111' R[t] = MVFR0;
        when '1000' R[t] = FPEXC;
        otherwise Unreachable(); // Dealt with above or in encoding-specific pseudocode
```

## F6.1.129 VMSR

Move general-purpose register to SIMD&FP Special register moves the value of a general-purpose register to a floating-point System register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

When these settings permit the execution of floating-point and Advanced SIMD instructions:

- If the specified floating-point System register is not the [FPSCR](#), the instruction is UNDEFINED if executed in User mode.
- If the specified floating-point System register is the [FPEXC](#) and the instruction is executed in a mode other than User mode the instruction is ignored.

```
t = UInt(Rt);
if reg != '000x' && reg != '1000' then UNPREDICTABLE;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### CONSTRAINED UNPREDICTABLE behavior

If `reg != '000x' && reg != '1000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using VMSR at the same Exception level.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<C> See [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<spec\_reg> Is the destination Advanced SIMD and floating-point System register, encoded in the "reg" field. It can have the following values:

FPSID                      when reg = 0000

FPSCR                      when reg = 0001

FPEXC                      when reg = 1000

The following encodings are UNPREDICTABLE:

- reg = 001x.
- reg = 01xx.
- reg = 1001.
- reg = 101x.
- reg = 11xx.

<Rt> Is the general-purpose source register, encoded in the "Rt" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then // FPSCR
        CheckVFPEnabled(TRUE);
        FPSCR = R[t];
    elseif PSTATE.EL == EL0 then // Non-FPSCR registers accessible only at PL1 or above
        UNDEFINED;
    else
        CheckVFPEnabled(FALSE); // Non-FPSCR registers are not affected by FPEXC.EN
        case reg of
            when '0000' // VMSR access to FPSID is ignored
            when '1000' FPEXC = R[t];
            otherwise Unreachable(); // Dealt with above or in encoding-specific pseudocode
```

## F6.1.130 VMUL (floating-point)

Vector Multiply multiplies corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

## F6.1.131 VMUL (integer and polynomial)

Vector Multiply multiplies corresponding elements in two vectors.

For information about multiplying polynomials see [Polynomial arithmetic over {0, 1} on page A1-47](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

if size == '10' then esize = 32; elements = 2; m = UInt(Vm); index = UInt(M);
```

### CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2904](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2985](#) for the A32 instruction set.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the scalar and the elements of the operand vector, encoded in the "F:size" field. It can have the following values: I16          when F = 0, size = 01 I32          when F = 0, size = 10 F16          when F = 1, size = 01 F32          when F = 1, size = 10
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is I16, otherwise the "Vm" field.
<index>	Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is I16, otherwise in range 0 to 1, encoded in the "M" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize]; op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize]; op1val = Int(op1, unsigned);
            if floating_point then
                Elem[D[d+r],e,esize] = FPMul(op1, op2, StandardFPSCRValue());
            else
```

```
if long_destination then

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the operands, encoded in the "op:U:size" field. It can have the following values: <ul style="list-style-type: none"> <li>S8          when <code>op = 0, U = 0, size = 00</code></li> <li>S16        when <code>op = 0, U = 0, size = 01</code></li> <li>S32        when <code>op = 0, U = 0, size = 10</code></li> <li>U8          when <code>op = 0, U = 1, size = 00</code></li> <li>U16        when <code>op = 0, U = 1, size = 01</code></li> <li>U32        when <code>op = 0, U = 1, size = 10</code></li> <li>P8          when <code>op = 1, U = 0, size = 00</code></li> <li>P64        when <code>op = 1, U = 0, size = 10</code></li> </ul>
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize]; op1val = Int(op1, unsigned);
            op2 = Elem[Din[m+r],e,esize]; op2val = Int(op2, unsigned);
            if polynomial then
                product = PolynomialMult(op1,op2);
            else
                product = (op1val*op2val)<2*esize-1:0>;
            if long_destination then
                Elem[Q[d>1],e,2*esize] = product;
            else
                Elem[D[d+r],e,esize] = product<esize-1:0>;

```

### F6.1.134 VMULL (by scalar)

Vector Multiply Long multiplies each element in a vector by a scalar, and places the results in a second vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see [Advanced SIMD scalars on page F2-2874](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2904](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2985](#) for the A32 instruction set.

### Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.  
For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<dt>	Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values: <div> <div>S16      when U = 0, size = 01</div> <div>S32      when U = 0, size = 10</div> <div>U16      when U = 1, size = 01</div> <div>U32      when U = 1, size = 10</div> </div>
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16 or U16, otherwise the "Vm" field.
<index>	Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16 or U16, otherwise in range 0 to 1, encoded in the "M" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize]; op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize]; op1val = Int(op1, unsigned);
            if floating_point then
                Elem[D[d+r],e,esize] = FPMul(op1, op2, StandardFPSCRValue());
            else
                if long_destination then
                    Elem[Q[d>>1],e,2*esize] = (op1val*op2val)<2*esize-1:0>;
                else
                    Elem[D[d+r],e,esize] = (op1val*op2val)<esize-1:0>;

```

## F6.1.135 VMVN (immediate)

Vector Bitwise NOT (immediate) places the bitwise inverse of an immediate integer constant into every element of the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2912](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2994](#) for the A32 instruction set.

### Assembler symbols

<c>	For encoding A1, A2 and A3: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1, T2 and T3: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<imm>	Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see <a href="#">Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2865</a> .

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(imm64);
```

## F6.1.136 VMVN (register)

Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in the destination register. The registers can be either doubleword or quadword.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

VMVN{<C>}{<q>}{.<dt>} <Qd>, <Qm>

#### Decode for all variants of this encoding

```
if size != '00' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

### Assembler symbols

<C> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>\*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>\*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(D[m+r]);
```

## F6.1.137 VNEG

Vector Negate negates each element in a vector, and places the results in a second vector. The floating-point version only inverts the sign bit.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

  when '11' esize = 64; d = UInt(D:Vd); m = UInt(M:Vm);

```

### CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<C> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.

For encoding A2, T1 and T2: see [Standard assembler syntax fields on page F2-2848](#).

<Q> See [Standard assembler syntax fields on page F2-2848](#).

<dt> Is the data type for the elements of the vectors, encoded in the "F:size" field. It can have the following values:

S8	when F = 0, size = 00
S16	when F = 0, size = 01
S32	when F = 0, size = 10
F16	when F = 1, size = 01
F32	when F = 1, size = 10

<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDorVFPEEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        for r = 0 to regs-1
            for e = 0 to elements-1
                if floating_point then
                    Elem[D[d+r],e,esize] = FPNeg(Elem[D[m+r],e,esize]);
                else
                    result = -SInt(Elem[D[m+r],e,esize]);
                    Elem[D[d+r],e,esize] = result<size-1:0>;
            // VFP instruction
    else
        case esize of
            when 16 S[d] = Zeros(16) : FPNeg(S[m]<15:0>);
            when 32 S[d] = FPNeg(S[m]);
            when 64 D[d] = FPNeg(D[m]);

```

## F6.1.138 VNMLA

Vector Negate Multiply Accumulate multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

### ————— Note —————

ARM recommends that software does not use the VNMLA instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPExc registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

## F6.1.141 VORN (immediate)

Vector Bitwise OR NOT (immediate) performs a bitwise OR between a register value and the complement of an immediate value, and returns the result into the destination vector

This instruction is a pseudo-instruction of the [VORR \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VORR \(immediate\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VORR \(immediate\)](#) gives the operational pseudocode for this instruction.

### Assembler symbols

<c>	For encoding A1 and A2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1 and T2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<imm>	Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see <a href="#">Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2865</a> .

### Operation for all encodings

The description of [VORR \(immediate\)](#) gives the operational pseudocode for this instruction.

## F6.1.142 VORN (register)

Vector bitwise OR NOT (register) performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

## Assembler symbols

- <c> For encoding A1 and A2: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.
- For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2848](#).
- <q> See [Standard assembler syntax fields on page F2-2848](#).
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>\*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<imm> Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2865](#).

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] OR imm64;
```

## F6.1.144 VORR (register)

Vector bitwise OR (register) performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

This instruction is used by the pseudo-instructions [VMOV \(register, SIMD\)](#), [VRSHR \(zero\)](#), and [VSHR \(zero\)](#). The pseudo-instruction is never the preferred disassembly.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR D[m+r];

```

## F6.1.145 VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

The following figure shows the operation of VPADAL doubleword operation for data type S16.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### Assembler symbols

<C>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional.  For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "op:size" field. It can have the following values:  S8            when op = 0, size = 00 S16          when op = 0, size = 01 S32          when op = 0, size = 10 U8            when op = 1, size = 00 U16          when op = 1, size = 01 U32          when op = 1, size = 10 The following encodings are reserved: <ul style="list-style-type: none"> <li>• op = 0, size = 11.</li> <li>• op = 1, size = 11.</li> </ul>
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    h = elements DIV 2;

    for r = 0 to regs-1
        for e = 0 to h-1
            op1 = Elem[D[m+r],2*e,esize]; op2 = Elem[D[m+r],2*e+1,esize];
            result = Int(op1, unsigned) + Int(op2, unsigned);
            Elem[D[d+r],e,2*esize] = Elem[D[d+r],e,2*esize] + result;
```

## F6.1.146 VPADD (floating-point)

Vector Pairwise Add (floating-point) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements are floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
1	1	1	1	0	0	1	1	0	D	0	sz	Vn	Vd	1	1	0	1	N	Q	M	0	Vm			

#### A1 variant

VPADD{<C>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

#### Decode for this encoding

```

if Q == '1' then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
case sz of
  when '0' esize = 32; elements = 2;
  when '1' esize = 16; elements = 4;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);

```

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	10	9	8	7	6	5	4	3	0
1	1	1	1	1	1	1	1	0	D	0	sz	Vn	Vd	1	1	0	1	N	Q	M	0	Vm			

#### T1 variant

VPADD{<C>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

#### Decode for this encoding

```

if Q == '1' then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
if sz == '1' && InITBlock() then UNPREDICTABLE;
case sz of
  when '0' esize = 32; elements = 2;
  when '1' esize = 16; elements = 4;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);

```

#### CONSTRAINED UNPREDICTABLE behavior

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

## Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: F32           when sz = 0 F16           when sz = 1
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        Elem[dest,e,esize] = FPAdd(Elem[D[n],2*e,esize], Elem[D[n],2*e+1,esize],
StandardFPSCRValue());
        Elem[dest,e+h,esize] = FPAdd(Elem[D[m],2*e,esize], Elem[D[m],2*e+1,esize],
StandardFPSCRValue());

    D[d] = dest;

```

## F6.1.147 VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The following figure shows the operation of VPADD doubleword operation for data type I16.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#) on page G1-4413.

#### T1 variant

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

#### Decode for this encoding

```
if size == '11' || Q == '1' then UNDEFINED;
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

## Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values: I8           when size = 00 I16          when size = 01 I32          when size = 10
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        Elem[dest,e,esize] = Elem[D[n],2*e,esize] + Elem[D[n],2*e+1,esize];
        Elem[dest,e+h,esize] = Elem[D[m],2*e,esize] + Elem[D[m],2*e+1,esize];

    D[d] = dest;

```

## F6.1.148 VPADDL

Vector Pairwise Add Long adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

The following figure shows the operation of VPADDL doubleword operation for data type S16.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

VPADDL{<C>}{<q>}.<dt> <Dd>, <Dm>

### 128-bit SIMD vector variant

Applies when Q == 1.

VPADDL{<C>}{<q>}.<dt> <Qd>, <Qm>

### Decode for all variants of this encoding

```
if size == '11' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
unsigned = (op == '1');
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

### Assembler symbols

<C>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "op:size" field. It can have the following values: S8            when op = 0, size = 00 S16          when op = 0, size = 01 S32          when op = 0, size = 10 U8            when op = 1, size = 00 U16          when op = 1, size = 01 U32          when op = 1, size = 10 The following encodings are reserved: <ul style="list-style-type: none"> <li>op = 0, size = 11.</li> <li>op = 1, size = 11.</li> </ul>
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    h = elements DIV 2;

    for r = 0 to regs-1
        for e = 0 to h-1
            op1 = Elem[D[m+r],2*e,esize]; op2 = Elem[D[m+r],2*e+1,esize];
            result = Int(op1, unsigned) + Int(op2, unsigned);
            Elem[D[d+r],e,2*esize] = result<2*esize-1:0>;
```

## F6.1.149 VPMAX (floating-point)

Vector Pairwise Maximum compares adjacent pairs of elements in two doubleword vectors, and copies the larger of each pair into the corresponding element in the destination doubleword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

### A1 variant

VPMAX{<C>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

### Decode for this encoding

```

if Q == '1' then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
maximum = (op == '0');
case sz of
    when '0' esize = 32; elements = 2;
    when '1' esize = 16; elements = 4;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);

```

### T1

### T1 variant

VPMAX{<C>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

### Decode for this encoding

```

if Q == '1' then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
if sz == '1' && InITBlock() then UNPREDICTABLE;
maximum = (op == '0');
case sz of
    when '0' esize = 32; elements = 2;
    when '1' esize = 16; elements = 4;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);

```

### CONSTRAINED UNPREDICTABLE behavior

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

## Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: F32            when sz = 0 F16            when sz = 1
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        op1 = Elem[D[n],2*e,esize]; op2 = Elem[D[n],2*e+1,esize];
        Elem[dest,e,esize] = if maximum then FPMMax(op1,op2,StandardFPSCRValue()) else
FPMMin(op1,op2,StandardFPSCRValue());
        op1 = Elem[D[m],2*e,esize]; op2 = Elem[D[m],2*e+1,esize];
        Elem[dest,e+h,esize] = if maximum then FPMMax(op1,op2,StandardFPSCRValue()) else
FPMMin(op1,op2,StandardFPSCRValue());

    D[d] = dest;

```

## F6.1.150 VPMAX (integer)

Vector Pairwise Maximum compares adjacent pairs of elements in two doubleword vectors, and copies the larger of each pair into the corresponding element in the destination doubleword vector.

The following figure shows the operation of VPMAX doubleword operation for data type S16 or U16.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Increment After variant

VPOP{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

### Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<size> An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<sreglist> Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.

<dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

### Operation for all encodings

The description of [VLDM](#), [VLDMDB](#), [VLDMIA](#) gives the operational pseudocode for this instruction.

## F6.1.154 VPUSH

Push SIMD&FP registers to Stack stores multiple consecutive registers from the Advanced SIMD and floating-point register file to the stack

This instruction is an alias of the [VSTM](#), [VSTMDB](#), [VSTMIA](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VSTM](#), [VSTMDB](#), [VSTMIA](#).
- The description of [VSTM](#), [VSTMDB](#), [VSTMIA](#) gives the operational pseudocode for this instruction.

## T2

### Decrement Before variant

VPUSH{<C>}{<q>}{.<size>} <sreglist>

is equivalent to

VSTMDB{<C>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

### Assembler symbols

<C> See [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<size> An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<sreglist> Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.

<dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

### Operation for all encodings

The description of [VSTM](#), [VSTMDB](#), [VSTMIA](#) gives the operational pseudocode for this instruction.

## F6.1.155 VQABS

Vector Saturating Absolute takes the absolute value of each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2731](#).

Depending on settings in the **CPACR**, **NSACR**, and **HCPTTR** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

            if sat then FPSCR.QC = '1';

```

## F6.1.157 VQDMLAL

Vector Saturating Doubling Multiply Accumulate Long multiplies corresponding elements in two doubleword vectors, doubles the products, and accumulates the results into the elements of a quadword vector.

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars](#) on page F2-2874.

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode description of saturation](#) on page E1-2731.

Depending on settings in the **CPACR**, **NSACR**, and **HCPTTR** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#) on page G1-4413.

### Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2904](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2985](#) for the A32 instruction set.

### Assembler symbols

<c>	For encoding A1 and A2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1 and T2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values: S16            when size = 01 S32            when size = 10
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	For encoding A1 and T1: is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field. For encoding A2 and T2: is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16, otherwise the "Vm" field.
<index>	Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16, otherwise in range 0 to 1, encoded in the "M" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    if scalar_form then op2 = SInt(Elem[Din[m],index,esize]);
    for e = 0 to elements-1
        if !scalar_form then op2 = SInt(Elem[Din[m],e,esize]);
        op1 = SInt(Elem[Din[n],e,esize]);
        // The following only saturates if both op1 and op2 equal -(2^(esize-1))
        (product, sat1) = SignedSatQ(2*op1*op2, 2*esize);
        if add then
            result = SInt(Elem[Qin[d>>1],e,2*esize]) + SInt(product);
        else
            result = SInt(Elem[Qin[d>>1],e,2*esize]) - SInt(product);
        (Elem[Q[d>>1],e,2*esize], sat2) = SignedSatQ(result, 2*esize);
    if sat1 || sat2 then FPSCR.QC = '1';

```

## F6.1.158 VQDMLSL

Vector Saturating Doubling Multiply Subtract Long multiplies corresponding elements in two doubleword vectors, subtracts double the products from corresponding elements of a quadword vector, and places the results in the same quadword vector.

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars on page F2-2874](#).

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2731](#).

Depending on settings in the **CPACR**, **NSACR**, and **HCPTTR** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

## Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2904](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2985](#) for the A32 instruction set.

## Assembler symbols

<c>	For encoding A1 and A2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1 and T2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values: S16          when size = 01 S32          when size = 10
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	For encoding A1 and T1: is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field. For encoding A2 and T2: is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16, otherwise the "Vm" field.
<index>	Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16, otherwise in range 0 to 1, encoded in the "M" field.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    if scalar_form then op2 = SInt(Elem[Din[m],index,esize]);
    for e = 0 to elements-1
        if !scalar_form then op2 = SInt(Elem[Din[m],e,esize]);
        op1 = SInt(Elem[Din[n],e,esize]);
        // The following only saturates if both op1 and op2 equal -(2^(esize-1))
        (product, sat1) = SignedSatQ(2*op1*op2, 2*esize);
        if add then
            result = SInt(Elem[Qin[d>>1],e,2*esize]) + SInt(product);
        else
            result = SInt(Elem[Qin[d>>1],e,2*esize]) - SInt(product);
        (Elem[Q[d>>1],e,2*esize], sat2) = SignedSatQ(result, 2*esize);
    if sat1 || sat2 then FPSCR.QC = '1';
```

## F6.1.159 VQDMULH

Vector Saturating Doubling Multiply Returning High Half multiplies corresponding elements in two vectors, doubles the results, and places the most significant half of the final results in the destination vector. The results are truncated, for rounded results see [VQRDMULH](#).

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars on page F2-2874](#).

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2731](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

        (product, sat) = SignedSatQ(2*op1*op2, 2*esize);
        Elem[Q[d>>1],e,2*esize] = product;
        if sat then FPSCR.QC = '1';
```

## F6.1.161 VQMOVN, VQMOVUN

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2731](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

This instruction is used by the pseudo-instructions [VQRSHRN \(zero\)](#), [VQRSHRUN \(zero\)](#), [VQSHRN \(zero\)](#), and [VQSHRUN \(zero\)](#). The pseudo-instruction is never the preferred disassembly.

```

## Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values: S8           when size = 00 S16          when size = 01 S32          when size = 10 The encoding size = 11 is reserved.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = -SInt(Elem[D[m+r],e,esize]);
            (Elem[D[d+r],e,esize], sat) = SignedSatQ(result, esize);
            if sat then FPSCR.QC = '1';

```

## F6.1.163 VQRDMLAH

Vector Saturating Rounding Doubling Multiply Accumulate Returning High Half. This instruction multiplies the vector elements of the first source SIMD&FP register with either the corresponding vector elements of the second source SIMD&FP register or the value of a vector element of the second source SIMD&FP register, without saturating the multiply results, doubles the results, and accumulates the most significant half of the final results with the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2731](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

if size == '01' then esize = 16; elements = 4; m = UInt(Vm<2:0>); index = UInt(M:Vm<3>);
if size == '10' then esize = 32; elements = 2; m = UInt(Vm); index = UInt(M);

```

## Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2904](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2985](#) for the A32 instruction set.

## Assembler symbols

<c>	For encoding A1 and A2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional.  For encoding T1 and T2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:  S16           when size = 01 S32           when size = 10
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm[x]>	Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is S32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    if scalar_form then op2 = SInt(Elm[D[m],index,esize]);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = SInt(Elm[D[n+r],e,esize]);
            if !scalar_form then op2 = SInt(Elm[D[m+r],e,esize]);
            (result, sat) = SignedSatQ((2*op1*op2 + round_const) >> esize, esize);
            Elm[D[d+r],e,esize] = result;
            if sat then FPSCR.QC = '1';

```

## F6.1.166 VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see [VQSHL \(register\)](#).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2731](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

U32            when  $op<0> = 1$ , size = 01

U64            when  $op<0> = 1$ , size = 10

The following encodings are reserved:

- $op<0> = 0$ , size = 11.
- $op<0> = 1$ , size = 11.

<Dd>            Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm>            Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>\*2.

### Operation for all encodings

The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

## F6.1.168 VQRSHRN, VQRSHRUN

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the rounded results in a doubleword vector.

For truncated results, see [VQSHL \(register\)](#).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2731](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2912](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2994](#) for the A32 instruction set.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<type>	Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values: S           when U = 0 U           when U = 1

<size>	Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values: 8            when L = 0, imm6<5:3> = 001 16          when L = 0, imm6<5:3> = 01x 32          when L = 0, imm6<5:3> = 1xx 64          when L = 1, imm6<5:3> = xxx
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<imm>	Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            operand = Int(Elem[D[m+r],e,esize], src_unsigned);
            (result, sat) = SatQ(operand << shift_amount, esize, dest_unsigned);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSCR.QC = '1';

```

### F6.1.171 VQSHL (register)

Vector Saturating Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

The results are truncated. For rounded results, see [VQRSHL](#).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2731](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

is equivalent to

VQMOVN{<C>}{<q>}.<dt> <Dd>, <Qm>

and is never the preferred disassembly.

### Assembler symbols

- <C> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.  
For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).
- <q> See [Standard assembler syntax fields on page F2-2848](#).
- <dt> Is the data type for the elements of the operand, encoded in the "op<0>:size" field. It can have the following values:
- |     |                           |
|-----|---------------------------|
| S16 | when op<0> = 0, size = 00 |
| S32 | when op<0> = 0, size = 01 |
| S64 | when op<0> = 0, size = 10 |
| U16 | when op<0> = 1, size = 00 |

U32            when  $op<0> = 1$ , size = 01

U64            when  $op<0> = 1$ , size = 10

The following encodings are reserved:

- $op<0> = 0$ , size = 11.
- $op<0> = 1$ , size = 11.

<Dd>            Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm>            Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>\*2.

### Operation for all encodings

The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

## F6.1.173 VQSHRN, VQSHRUN

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the truncated results in a doubleword vector.

For rounded results, see [VQRSHRN](#), [VQRSHRUN](#).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2731](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.																

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            diff = Int(Elem[D[n+r],e,esize], unsigned) - Int(Elem[D[m+r],e,esize], unsigned);
            (Elem[D[d+r],e,esize], sat) = SatQ(diff, esize, unsigned);
            if sat then FPSCR.QC = '1';
```

## F6.1.176 VRADDHN

Vector Rounding Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are rounded. For truncated results, see [VADDHN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize] + round_const;
        Elem[D[d],e,esize] = result<2*esize-1:esize>;

```

## F6.1.177 VRECPE

Vector Reciprocal Estimate finds an approximate reciprocal of each element in the operand vector, and places the results in the destination vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see *Floating-point reciprocal square root estimate and step* on page E1-2750.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-4413.

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

### Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of a number, see [Floating-point reciprocal estimate and step on page E1-2749](#).

### Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                Elem[D[d+r],e,esize] = FPREstimate(Elem[D[m+r],e,esize], StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = UnsignedRecipEstimate(Elem[D[m+r],e,esize]);

```

## F6.1.178 VRECPS

Vector Reciprocal Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see [Floating-point reciprocal estimate and step on page E1-2749](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

## T1

### 64-bit SIMD vector variant

Applies when Q == 0.

VREV32{<C>}{<q>}.<dt> <Dd>, <Dm>

### 128-bit SIMD vector variant

Applies when Q == 1.

VREV32{<C>}{<q>}.<dt> <Qd>, <Qm>

### Decode for all variants of this encoding

```

if UInt(op)+UInt(size) >= 3 then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;

esize = 8 << UInt(size);
integer container_size;
case op of
    when '10' container_size = 16;
    when '01' container_size = 32;
    when '00' container_size = 64;
integer containers = 64 DIV container_size;
integer elements_per_container = container_size DIV esize;

d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

```

### Assembler symbols

- <C> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.
- For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).
- <q> See [Standard assembler syntax fields on page F2-2848](#).
- <dt> Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
- |    |                |
|----|----------------|
| 8  | when size = 00 |
| 16 | when size = 01 |
- The encoding size = 1x is reserved.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>\*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>\*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();

bits(64) result;

```

```
integer element;
integer rev_element;
for r = 0 to regs-1
    element = 0;
    for c = 0 to containers-1
        rev_element = element + elements_per_container - 1;
        for e = 0 to elements_per_container-1
            Elem[result, rev_element, esize] = Elem[D[m+r], element, esize];
            element = element + 1;
            rev_element = rev_element - 1;
        D[d+r] = result;
```

## F6.1.181 VREV64

Vector Reverse in doublewords reverses the order of 8-bit, 16-bit, or 32-bit elements in each doubleword of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

The following figure shows the operation of VREV64 doubleword operations.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

                rev_element = rev_element - 1;
            D[d+r] = result;
```

## F6.1.182 VRHADD

Vector Rounding Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector.

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The results of the halving operations are rounded. For truncated results, see [VHADD](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

            Elem[D[d+r],e,esize] = result<size:1>;
```

## F6.1.183 VRINTA (Advanced SIMD)

Vector Round floating-point to integer towards Nearest with Ties to Away rounds a vector of floating-point values to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

### A1

#### 64-bit SIMD vector variant

Applies when Q == 0.

VRINTA{<q>}.<dt> <Dd>, <Dm>

#### 128-bit SIMD vector variant

Applies when Q == 1.

VRINTA{<q>}.<dt> <Qd>, <Qm>

#### Decode for all variants of this encoding

```

if op<2> != op<0> then SEE "Related encodings";
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && !HaveFP16Ext()) || size IN {'00', '11'} then UNDEFINED;
// Rounding encoded differently from other VCVT and VRINT instructions
rounding = FPDecodeRM(op<2>:NOT(op<1>)); exact = FALSE;
case size of
    when '01' esize = 16; elements = 4;
    when '10' esize = 32; elements = 2;
d = UInt(D:Dd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

```

### T1

#### 64-bit SIMD vector variant

Applies when Q == 0.

VRINTA{<q>}.<dt> <Dd>, <Dm>

#### 128-bit SIMD vector variant

Applies when Q == 1.

VRINTA{<q>}.<dt> <Qd>, <Qm>

#### Decode for all variants of this encoding

```

if op<2> != op<0> then SEE "Related encodings";
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && !HaveFP16Ext()) || size IN {'00', '11'} then UNDEFINED;
// Rounding encoded differently from other VCVT and VRINT instructions

```

```

rounding = FPDecodeRM(op<2>:NOT(op<1>)); exact = FALSE;
case size of
    when '01' esize = 16; elements = 4;
    when '10' esize = 32; elements = 2;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
if InITBlock() then UNPREDICTABLE;

```

### CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Notes for all encodings

Related encodings: See [Advanced SIMD two registers misc on page F3-2907](#) for the T32 instruction set, or [Advanced SIMD two registers misc on page F4-2989](#) for the A32 instruction set.

### Assembler symbols

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .

```

## F6.1.186 VRINTM (floating-point)

Round floating-point to integer towards -Infinity rounds a floating-point value to an integral floating-point value of the same size using the Round towards -Infinity rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

VRINTM{<q>}.F32 <Sd>, <Sm>

#### Double-precision scalar variant

Applies when size == 11.

VRINTM{<q>}.F64 <Dd>, <Dm>

### Decode for all variants of this encoding

```
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
rounding = FPDecodeRM(RM); exact = FALSE;
case size of
  when '01' esize = 16; d = UInt(Vd:D); m = UInt(Vm:M);
  when '10' esize = 32; d = UInt(Vd:D); m = UInt(Vm:M);
  when '11' esize = 64; d = UInt(D:Vd); m = UInt(M:Vm);
if InITBlock() then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

```

## F6.1.192 VRINTX (Advanced SIMD)

Vector round floating-point to integer inexact rounds a vector of floating-point values to integral floating-point values of the same size, using the Round to Nearest rounding mode, and raises the Inexact exception when the result value is not numerically equal to the input value. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

    d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    if InITBlock() then UNPREDICTABLE;

```

### CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values: F16          when size = 01 F32          when size = 10
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

  when 64
    D[d] = FPRoundInt(D[m], FPSCR, rounding, exact);
```

## F6.1.196 VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see VSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2912](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2994](#) for the A32 instruction set.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<type>	Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values: S           when U = 0 U           when U = 1
<size>	Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values: 8           when L = 0, imm6<5:3> = 001 16          when L = 0, imm6<5:3> = 01x 32          when L = 0, imm6<5:3> = 1xx 64          when L = 1, imm6<5:3> = xxx
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<imm>	Is an immediate value, in the range 1 to <size>, encoded in the "imm6" field as <size> - <imm>.

### Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  round_const = 1 << (shift_amount - 1);
  for r = 0 to regs-1
    for e = 0 to elements-1
      result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) >> shift_amount;
      Elem[D[d+r],e,esize] = result<esize-1:0>;

```

## F6.1.198 VRSHR (zero)

Vector Rounding Shift Right copies the contents of one SIMD register to another

This instruction is a pseudo-instruction of the [VORR \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VORR \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

### A1

VORR{<C>}{<q>}{.dt} <Dd>, <Dm>, <Dm>

and is never the preferred disassembly.

#### 128-bit SIMD vector variant

Applies when Q == 1.

$\text{VRSHR}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \langle Qd \rangle, \langle Qm \rangle, \#0$

is equivalent to

$\text{VORR}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \langle Qd \rangle, \langle Qm \rangle, \langle Qm \rangle$

and is never the preferred disassembly.

### Assembler symbols

$\langle c \rangle$	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
$\langle q \rangle$	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
$\langle dt \rangle$	Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.
$\langle Qd \rangle$	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as $\langle Qd \rangle * 2$ .
$\langle Qm \rangle$	Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as $\langle Qm \rangle * 2$ .
$\langle Dd \rangle$	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
$\langle Dm \rangle$	Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

### Operation for all encodings

The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

## F6.1.199 VRSHRN

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see [VSHRN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

#### 64-bit SIMD vector variant

Applies when Q == 0.

VRSQRTE{<c>}{<q>}.<dt> <Dd>, <Dm>

#### 128-bit SIMD vector variant

Applies when Q == 1.

VRSQRTE{<c>}{<q>}.<dt> <Qd>, <Qm>

### Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && !HaveFP16Ext()) || size IN {'00', '11'} then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
floating_point = (F == '1');
case size of
    when '01' esize = 16; elements = 4;
    when '10' esize = 32; elements = 2;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

```

### CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "F:size" field. It can have the following values: <div style="margin-left: 20px;"> U32        when F = 0, size = 10  F16        when F = 1, size = 01  F32        when F = 1, size = 10 </div>
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

### Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see [Floating-point reciprocal estimate and step on page E1-2749](#).

### Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                Elem[D[d+r],e,esize] = FPRSqrtEstimate(Elem[D[m+r],e,esize], StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = UnsignedRSqrtEstimate(Elem[D[m+r],e,esize]);

```

## F6.1.202 VRSQRTS

Vector Reciprocal Square Root Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 3.0, divides these results by 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see [Floating-point reciprocal estimate and step on page E1-2749](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2912](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2994](#) for the A32 instruction set.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional.  For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<type>	Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:  S           when U = 0 U           when U = 1
<size>	Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:  8           when L = 0, imm6<5:3> = 001 16          when L = 0, imm6<5:3> = 01x 32          when L = 0, imm6<5:3> = 1xx 64          when L = 1, imm6<5:3> = xxx
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<imm>	Is an immediate value, in the range 1 to <size>, encoded in the "imm6" field as <size> - <imm>.

### Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount - 1);
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) >> shift_amount;
            Elem[D[d+r],e,esize] = Elem[D[d+r],e,esize] + result;

```

## F6.1.204 VRSUBHN

Vector Rounding Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are rounded. For truncated results, see [VSUBHN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### **VSELVS,singleprec variant**

Applies when cc == 01 && size == 10.

VSELVS.F32 <Sd>, <Sn>, <Sm> // Not permitted in IT block

### **Decode for all variants of this encoding**

```
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
case size of
  when '01' esize = 16; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
  when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
  when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
cond = cc:(cc<1> EOR cc<0>):'0';
if InITBlock() then UNPREDICTABLE;
```

### **CONSTRAINED UNPREDICTABLE behavior**

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### **Assembler symbols**

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.

## Operation for all encodings

```
EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
case esize of
  when 16
    S[d] = Zeros(16) : (if ConditionHolds(cond) then S[n] else S[m])<15:0>;
  when 32
    S[d] = if ConditionHolds(cond) then S[n] else S[m];
  when 64
    D[d] = if ConditionHolds(cond) then D[n] else D[m];
```

## F6.1.206 VSHL (immediate)

Vector Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in the destination vector.

Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2912](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2994](#) for the A32 instruction set.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values: 8            when L = 0, imm6<5:3> = 001 16          when L = 0, imm6<5:3> = 01x 32          when L = 0, imm6<5:3> = 1xx 64          when L = 1, imm6<5:3> = xxx
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<imm>	Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

### Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = LSL(Elem[D[m+r],e,esize], shift_amount);

```

## F6.1.207 VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

For a rounding shift, see [VRSHL](#).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); m = UInt(M:Vm); n = UInt(N:Vn); regs = if Q == '0' then 1 else 2;
```

### Assembler symbols

<C>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "U:size" field. It can have the following values: <div style="margin-left: 20px;"> S8           when U = 0, size = 00  S16          when U = 0, size = 01  S32          when U = 0, size = 10  S64          when U = 0, size = 11  U8           when U = 1, size = 00  U16          when U = 1, size = 01  U32          when U = 1, size = 10  U64          when U = 1, size = 11 </div>
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            result = Int(Elem[D[m+r],e,esize], unsigned) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

## F6.1.208 VSHLL

Vector Shift Left Long takes each element in a doubleword vector, left shifts them by an immediate value, and places the results in a quadword vector.

The operand elements can be:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit untyped integers, maximum shift only.

The result elements are twice the length of the operand elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Decode for this encoding

```

if size == '11' || Vd<0> == '1' then UNDEFINED;
esize = 8 << UInt(size); elements = 64 DIV esize; shift_amount = esize;
unsigned = FALSE; // Or TRUE without change of functionality
d = UInt(D:Vd); m = UInt(M:Vm);

```

## Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2912](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2994](#) for the A32 instruction set.

## Assembler symbols

<C>	For encoding A1 and A2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1 and T2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<type>	The data type for the elements of the operand. It must be one of: S Signed. In encoding T1/A1, encoded as U = 0. U Unsigned. In encoding T1/A1, encoded as U = 1. I Untyped integer, Available only in encoding T2/A2.

<size> The data size for the elements of the operand. The following table shows the permitted values and their encodings:

<size>	Encoding T1/A1	Encoding T2/A2
8	Encoded as imm6<5:3> = 0b001	Encoded as size = 0b00
16	Encoded as imm6<5:4> = 0b01	Encoded as size = 0b01
32	Encoded as imm6<5> = 1	Encoded as size = 0b10

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>\*2.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> The immediate value. <imm> must lie in the range 1 to <size>, and:

- If <size> == <imm>, the encoding is T2/A2.
- Otherwise, the encoding is T1/A1, and:
  - If <size> == 8, <imm> is encoded in imm6<2:0>.
  - If <size> == 16, <imm> is encoded in imm6<3:0>.
  - If <size> == 32, <imm> is encoded in imm6<4:0>.

### Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned) << shift_amount;
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;

```

## F6.1.209 VSHR

Vector Shift Right takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see [VRSHR](#).

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
<imm>	Is an immediate value, in the range 1 to <size>, encoded in the "imm6" field as <size> - <imm>.

### Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      result = Int(Elem[D[m+r],e,esize], unsigned) >> shift_amount;
      Elem[D[d+r],e,esize] = result<size-1:0>;

```

## F6.1.210 VSHR (zero)

Vector Shift Right copies the contents of one SIMD register to another

This instruction is a pseudo-instruction of the [VORR \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VORR \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

### A1

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
1	1	1	1	0	0	1	0	0	D	1	0	Vn	Vd	0	0	0	1	N	Q	M	1	Vm			

#### 64-bit SIMD vector variant

Applies when Q == 0.

VSHR{<C>}{<q>}.<dt> <Dd>, <Dm>, #0

is equivalent to

VORR{<C>}{<q>}{.dt>} <Dd>, <Dm>, <Dm>

and is never the preferred disassembly.

#### 128-bit SIMD vector variant

Applies when Q == 1.

VSHR{<C>}{<q>}.<dt> <Qd>, <Qm>, #0

is equivalent to

VORR{<C>}{<q>}{.dt>} <Qd>, <Qm>, <Qm>

and is never the preferred disassembly.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	10	9	8	7	6	5	4	3	0

#### 64-bit SIMD vector variant

Applies when Q == 0.

VSHR{<C>}{<q>}.<dt> <Dd>, <Dm>, #0

is equivalent to

VORR{<C>}{<q>}{.dt>} <Dd>, <Dm>, <Dm>

and is never the preferred disassembly.

#### 128-bit SIMD vector variant

Applies when Q == 1.

$VSHR\{\langle C \rangle\}\{\langle Q \rangle\}.\langle dt \rangle \langle Qd \rangle, \langle Qm \rangle, \#0$

is equivalent to

$VORR\{\langle C \rangle\}\{\langle Q \rangle\}\{\langle dt \rangle\} \langle Qd \rangle, \langle Qm \rangle, \langle Qm \rangle$

and is never the preferred disassembly.

### Assembler symbols

$\langle C \rangle$	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
$\langle Q \rangle$	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
$\langle dt \rangle$	Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.
$\langle Qd \rangle$	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as $\langle Qd \rangle * 2$ .
$\langle Qm \rangle$	Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as $\langle Qm \rangle * 2$ .
$\langle Dd \rangle$	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
$\langle Dm \rangle$	Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

### Operation for all encodings

The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

## F6.1.211 VSHRN

Vector Shift Right Narrow takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see [VRSHRN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

## Assembler symbols

- <C> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.  
For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).
- <q> See [Standard assembler syntax fields on page F2-2848](#).
- <dt> Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:
- |     |                |
|-----|----------------|
| I16 | when size = 00 |
| I32 | when size = 01 |
| I64 | when size = 10 |
- The encoding size = 11 is reserved.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>\*2.

### **Operation for all encodings**

The description of [VMOVN](#) gives the operational pseudocode for this instruction.

## F6.1.213 VSLI

Vector Shift Left and Insert takes each element in the operand vector, left shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2912](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2994](#) for the A32 instruction set.

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .								
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .								
<size>	Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values: <table> <tr> <td>8</td><td>when L = 0, imm6&lt;5:3&gt; = 001</td></tr> <tr> <td>16</td><td>when L = 0, imm6&lt;5:3&gt; = 01x</td></tr> <tr> <td>32</td><td>when L = 0, imm6&lt;5:3&gt; = 1xx</td></tr> <tr> <td>64</td><td>when L = 1, imm6&lt;5:3&gt; = xxx</td></tr> </table>	8	when L = 0, imm6<5:3> = 001	16	when L = 0, imm6<5:3> = 01x	32	when L = 0, imm6<5:3> = 1xx	64	when L = 1, imm6<5:3> = xxx
8	when L = 0, imm6<5:3> = 001								
16	when L = 0, imm6<5:3> = 01x								
32	when L = 0, imm6<5:3> = 1xx								
64	when L = 1, imm6<5:3> = xxx								
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.								
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.								
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.								
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.								
<imm>	Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.								

### Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  mask = LSL(Ones(esize), shift_amount);
  for r = 0 to regs-1
    for e = 0 to elements-1
      shifted_op = LSL(Elm[D[m+r],e,esize], shift_amount);
      Elm[D[d+r],e,esize] = (Elm[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;

```

## F6.1.214 VSQRT

Square Root calculates the square root of the value in a floating-point register and writes the result to another floating-point register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Single-precision scalar variant

Applies when size == 10.

VSQRT{<c>}{<q>}.F32 <Sd>, <Sm>

### Double-precision scalar variant

Applies when size == 11.

VSQRT{<c>}{<q>}.F64 <Dd>, <Dm>

### Decode for all variants of this encoding

```
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
if size == '01' && InITBlock() then UNPREDICTABLE;
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
case size of
  when '01' esize = 16; d = UInt(Vd:D); m = UInt(Vm:M);
  when '10' esize = 32; d = UInt(Vd:D); m = UInt(Vm:M);
  when '11' esize = 64; d = UInt(D:Vd); m = UInt(M:Vm);
```

### CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

### Assembler symbols

<c>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
case esize of
  when 16 S[d] = Zeros(16) : FPSqrt(S[m]<15:0>, FPSCR);
  when 32 S[d] = FPSqrt(S[m], FPSCR);
  when 64 D[d] = FPSqrt(D[m], FPSCR);
```

## F6.1.215 VSRA

Vector Shift Right and Accumulate takes each element in a vector, right shifts them by an immediate value, and accumulates the truncated results into the destination vector. For rounded results, see [VRSRA](#).

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<c>	For encoding A1, A2 and A3: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional.  For encoding T1, T2 and T3: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values:  8           when size = 00 16          when size = 01 32          when size = 10
<list>	Is a list containing the single 64-bit name of the SIMD&FP register holding the element. The list must be { <Dd>[<index>] }. The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:  <size> == 8           <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field. <size> == 16          <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field. <size> == 32          <index> is 0 or 1, encoded in the "index_align<3>" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2777](#), and the encoding depends on <size>:

<size> == 8            Encoded in the "index\_align<0>" field as 0.  
<size> == 16           Encoded in the "index\_align<1:0>" field as 0b00.  
<size> == 32           Encoded in the "index\_align<2:0>" field as 0b000.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 16           <align> is 16, meaning 16-bit alignment, encoded in the  
                             "index\_align<1:0>" field as 0b01.  
<size> == 32           <align> is 32, meaning 32-bit alignment, encoded in the  
                             "index\_align<2:0>" field as 0b011.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2869](#).

<Rm>            Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address,ebytes] = Elem[D[d],index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
```

## F6.1.218 VST1 (multiple single elements)

Store multiple single elements from one, two, three, or four registers stores elements to memory from one, two, three, or four registers, without interleaving. Every element of each register is stored. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
1	1	1	1	0	1	0	0	0	D	0	0	Rn		Vd		0	1	1	1	size	align		Rm		

#### Offset variant

Applies when Rm == 1111.

VST1{<C>}{<q>}.<size> <list>, [<Rn>{:<align>}]

#### Post-indexed variant

Applies when Rm == 1101.

VST1{<C>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

#### Post-indexed variant

Applies when Rm != 11x1.

VST1{<C>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

#### Decode for all variants of this encoding

```
regs = 1; if align<1> == '1' then UNDEFINED;
alignment = if align == '00' then 1 else 4 << UInt(align);
ebytes = 1 << UInt(size); elements = 8 DIV ebytes;
d = UInt(D:Vd); n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Selects the A2 and T2 encodings of the instruction.	{ <Dd>, <Dd+1>, <Dd+2> }	Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.	{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }	Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.
{ <Dd> }	Single register. Selects the A1 and T1 encodings of the instruction.								
{ <Dd>, <Dd+1> }	Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.								
{ <Dd>, <Dd+1>, <Dd+2> }	Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.								
{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }	Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.								
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.								
<align>	Is the optional alignment.  Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access on page E2-2777</a> , and is encoded in the "align" field as 0b00.  Whenever <align> is present, the permitted values are:  <table> <tr><td>64</td><td>64-bit alignment, encoded in the "align" field as 0b01.</td></tr> <tr><td>128</td><td>128-bit alignment, encoded in the "align" field as 0b10. Available only if &lt;list&gt; contains two or four registers.</td></tr> <tr><td>256</td><td>256-bit alignment, encoded in the "align" field as 0b11. Available only if &lt;list&gt; contains four registers.</td></tr> </table> : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see <a href="#">The Advanced SIMD addressing mode on page F2-2869</a> .	64	64-bit alignment, encoded in the "align" field as 0b01.	128	128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.	256	256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.		
64	64-bit alignment, encoded in the "align" field as 0b01.								
128	128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.								
256	256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.								
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.								

For more information about <Rn>, !, and <Rm>, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);

```

```

for r = 0 to regs-1
  for e = 0 to elements-1
    if ebytes != 8 then
      MemU[address,ebytes] = Elem[D[d+r],e];
    else
      - = AArch32.CheckAlignment(address, ebytes, AccType_NORMAL, iswrite);
      bits(64) data = Elem[D[d+r],e];
      MemU[address,4] = if BigEndian() then data<63:32> else data<31:0>;
      MemU[address+4,4] = if BigEndian() then data<31:0> else data<63:32>;
      address = address + ebytes;
  if wback then
    if register_index then
      R[n] = R[n] + R[m];
    else
      R[n] = R[n] + 8*regs;

```

## F6.1.219 VST2 (single 2-element structure from one lane)

Store single 2-element structure from one lane of two registers stores one 2-element structure to memory from corresponding elements of two registers. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	4	3	0
1	1	1	1	0	1	0	0	1	D	0	0	Rn	Vd	0	0	0	1	index_align	Rm				
												size											

#### Offset variant

Applies when Rm == 1111.

VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

#### Post-indexed variant

Applies when Rm == 1101.

VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

#### Post-indexed variant

Applies when Rm != 11x1.

VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

#### Decode for all variants of this encoding

```
if size == '11' then UNDEFINED;
ebytes = 1; index = UInt(index_align<3:1>); inc = 1;
alignment = if index_align<0> == '0' then 1 else 2;
d = UInt(D:Vd); d2 = d + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

inc = if index_align<2> == '0' then 1 else 2;
alignment = if index_align<0> == '0' then 1 else 8;
d = UInt(D:Vd); d2 = d + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If  $d2 > 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST2 (single 2-element structure from one lane)* on page K1-6113.

### Assembler symbols

<C>	For encoding A1, A2 and A3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848. This encoding must be unconditional. For encoding T1, T2 and T3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8            when size = 00 16          when size = 01 32          when size = 10
<list>	Is a list containing the 64-bit names of the two SIMD&FP registers holding the element. The list must be one of: { <Dd>[<index>], <Dd+1>[<index>] } Single-spaced registers, encoded as "spacing" = 0. { <Dd>[<index>], <Dd+2>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> == 16 "spacing" is encoded in the "index\_align<1>" field.

<size> == 32 "spacing" is encoded in the "index\_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8 <index> is in the range 0 to 7, encoded in the "index\_align<3:1>" field.

<size> == 16 <index> is in the range 0 to 3, encoded in the "index\_align<3:2>" field.

<size> == 32 <index> is 0 or 1, encoded in the "index\_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2777](#), and the encoding depends on <size>:

<size> == 8 Encoded in the "index\_align<0>" field as 0.

<size> == 16 Encoded in the "index\_align<0>" field as 0.

<size> == 32 Encoded in the "index\_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 8 <align> is 16, meaning 16-bit alignment, encoded in the "index\_align<0>" field as 1.

<size> == 16 <align> is 32, meaning 32-bit alignment, encoded in the "index\_align<0>" field as 1.

<size> == 32 <align> is 64, meaning 64-bit alignment, encoded in the "index\_align<1:0>" field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2869](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address, ebytes] = Elem[D[d], index];
    MemU[address+ebytes,ebytes] = Elem[D[d2],index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
```

## F6.1.220 VST2 (multiple 2-element structures)

Store multiple 2-element structures from two or four registers stores multiple 2-element structures from two or four registers to memory, with interleaving. For more information, see [Element and structure load/store instructions on page F1-2829](#). Every element of each register is saved. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

d = UInt(D:Vd); d2 = d + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d2+regs > 32 then UNPREDICTABLE;
```

## CONSTRAINED UNPREDICTABLE behavior

If  $d2+regs > 32$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

## Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST2 (multiple 2-element structures)* on page K1-6112.

Related encodings: See [Advanced SIMD element or structure load/store on page F3-2922](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store on page F4-2997](#) for the A32 instruction set.

## Assembler symbols

<c>	For encoding A1 and A2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1 and T2: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8            when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<list>	Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of: { <Dd>, <Dd+1> }      Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1000. { <Dd>, <Dd+2> }      Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "type" field as 0b1001. { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Three single-spaced registers. Selects the A2 and T2 encodings of the instruction. The register <Dd> is encoded in the "D:Vd" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access on page E2-2777</a> , and is encoded in the "align" field as 0b00. Whenever <align> is present, the permitted values are: 64            64-bit alignment, encoded in the "align" field as 0b01. 128          128-bit alignment, encoded in the "align" field as 0b10. 256          256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2869](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to regs-1
        for e = 0 to elements-1
            MemU[address, ebytes] = Elem[D[d+r], e];
            MemU[address+ebytes, ebytes] = Elem[D[d2+r], e];
            address = address + 2*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 16*regs;
```

## F6.1.221 VST3 (single 3-element structure from one lane)

Store single 3-element structure from one lane of three registers stores one 3-element structure to memory from corresponding elements of three registers. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

if n == 15 || d3 > 31 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If  $d3 > 31$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST3 (single 3-element structure from one lane)* on page K1-6113.

### Assembler symbols

<C>	For encoding A1, A2 and A3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848. This encoding must be unconditional. For encoding T1, T2 and T3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848.						
<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.						
<size>	Is the data size, encoded in the "size" field. It can have the following values: <table> <tr> <td>8</td><td>when size = 00</td></tr> <tr> <td>16</td><td>when size = 01</td></tr> <tr> <td>32</td><td>when size = 10</td></tr> </table>	8	when size = 00	16	when size = 01	32	when size = 10
8	when size = 00						
16	when size = 01						
32	when size = 10						
<list>	Is a list containing the 64-bit names of the three SIMD&FP registers holding the element. The list must be one of: { <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] } Single-spaced registers, encoded as "spacing" = 0. { <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.						

The encoding of "spacing" depends on <size>:

<size> == 8           "spacing" is encoded in the "index\_align<0>" field.  
 <size> == 16         "spacing" is encoded in the "index\_align<1>" field, and "index\_align<0>" is set to 0.  
 <size> == 32         "spacing" is encoded in the "index\_align<2>" field, and "index\_align<1:0>" is set to 0b00.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8           <index> is in the range 0 to 7, encoded in the "index\_align<3:1>" field.  
 <size> == 16         <index> is in the range 0 to 3, encoded in the "index\_align<3:2>" field.  
 <size> == 32         <index> is 0 or 1, encoded in the "index\_align<3>" field.

<Rn>           Is the general-purpose base register, encoded in the "Rn" field.

<Rm>           Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

### Alignment

Standard alignment rules apply, see [Alignment support on page B2-102](#).

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];
    MemU[address, ebytes] = Elem[D[d], index];
    MemU[address+ebytes, ebytes] = Elem[D[d2], index];
    MemU[address+2*ebytes, ebytes] = Elem[D[d3], index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 3*ebytes;
```

## F6.1.222 VST3 (multiple 3-element structures)

Store multiple 3-element structures from three registers stores multiple 3-element structures to memory from three registers, with interleaving. For more information, see [Element and structure load/store instructions on page F1-2829](#). Every element of each register is saved. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

```

### CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST3 (multiple 3-element structures)* on page K1-6113.

Related encodings: See *Advanced SIMD element or structure load/store* on page F3-2922 for the T32 instruction set, or *Advanced SIMD element or structure load/store* on page F4-2997 for the A32 instruction set.

## Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8           when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<list>	Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of: { <Dd>, <Dd+1>, <Dd+2> } Single-spaced registers, encoded in the "type" field as 0b0100. { <Dd>, <Dd+2>, <Dd+4> } Double-spaced registers, encoded in the "type" field as 0b0101. The register <Dd> is encoded in the "D:Vd" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access on page E2-2777</a> , and is encoded in the "align" field as 0b00. Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b01. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see <a href="#">The Advanced SIMD addressing mode on page F2-2869</a> .
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        MemU[address, ebytes] = Elem[D[d], e];
        MemU[address+ebytes, ebytes] = Elem[D[d2],e];
        MemU[address+2*ebytes,ebytes] = Elem[D[d3],e];
        address = address + 3*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 24;

```

### F6.1.223 VST4 (single 4-element structure from one lane)

Store single 4-element structure from one lane of four registers stores one 4-element structure to memory from corresponding elements of four registers. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

ebytes = 4; index = UInt(index_align<3>);
inc = if index_align<2> == '0' then 1 else 2;
alignment = if index_align<1:0> == '00' then 1 else 4 << UInt(index_align<1:0>);
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; d4 = d3 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

#### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST4 (single 4-element structure from one lane)* on page K1-6113.

#### Assembler symbols

<c>	For encoding A1, A2 and A3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848. This encoding must be unconditional. For encoding T1, T2 and T3: see <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2848.
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8            when size = 00 16          when size = 01 32          when size = 10
<list>	Is a list containing the 64-bit names of the four SIMD&FP registers holding the element. The list must be one of: { <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] } Single-spaced registers, encoded as "spacing" = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] }

Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> == 16 "spacing" is encoded in the "index\_align<1>" field.

<size> == 32 "spacing" is encoded in the "index\_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8 <index> is in the range 0 to 7, encoded in the "index\_align<3:1>" field.

<size> == 16 <index> is in the range 0 to 3, encoded in the "index\_align<3:2>" field.

<size> == 32 <index> is 0 or 1, encoded in the "index\_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2777](#), and the encoding depends on <size>:

<size> == 8 Encoded in the "index\_align<0>" field as 0.

<size> == 16 Encoded in the "index\_align<0>" field as 0.

<size> == 32 Encoded in the "index\_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 8 <align> is 32, meaning 32-bit alignment, encoded in the "index\_align<0>" field as 1.

<size> == 16 <align> is 64, meaning 64-bit alignment, encoded in the "index\_align<0>" field as 1.

<size> == 32 <align> can be 64 or 128. 64-bit alignment is encoded in the "index\_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index\_align<1:0>" field as 0b10.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2869](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address, ebytes] = E1em[D[d], index];
    MemU[address+ebytes, ebytes] = E1em[D[d2], index];
    MemU[address+2*ebytes, ebytes] = E1em[D[d3], index];
    MemU[address+3*ebytes, ebytes] = E1em[D[d4], index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
```

## F6.1.224 VST4 (multiple 4-element structures)

Store multiple 4-element structures from four registers stores multiple 4-element structures to memory from four registers, with interleaving. For more information, see [Element and structure load/store instructions on page F1-2829](#). Every element of each register is saved. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2869](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

### CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST4 \(multiple 4-element structures\)](#) on page K1-6113.

Related encodings: See [Advanced SIMD element or structure load/store on page F3-2922](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store on page F4-2997](#) for the A32 instruction set.

## Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<size>	Is the data size, encoded in the "size" field. It can have the following values: 8           when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<list>	Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of: { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Single-spaced registers, encoded in the "type" field as 0b0000. { <Dd>, <Dd+2>, <Dd+4>, <Dd+6> } Double-spaced registers, encoded in the "type" field as 0b0001. The register <Dd> is encoded in the "D:Vd" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see <a href="#">Unaligned data access on page E2-2777</a> , and is encoded in the "align" field as 0b00. Whenever <align> is present, the permitted values are: 64           64-bit alignment, encoded in the "align" field as 0b01. 128          128-bit alignment, encoded in the "align" field as 0b10. 256          256-bit alignment, encoded in the "align" field as 0b11. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see <a href="#">The Advanced SIMD addressing mode on page F2-2869</a> .
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2869](#).

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        MemU[address, ebytes] = Elem[D[d], e];
        MemU[address+ebytes, ebytes] = Elem[D[d2], e];
        MemU[address+2*ebytes, ebytes] = Elem[D[d3], e];
        MemU[address+3*ebytes, ebytes] = Elem[D[d4], e];
        address = address + 4*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 32;

```

### F6.1.225 VSTM, VSTMDB, VSTMIA

Store multiple SIMD&FP registers stores multiple registers from the Advanced SIMD and floating-point register file to consecutive memory locations using an address from a general-purpose register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

This instruction is used by the alias **VPUSH**. See *Alias conditions* on page F6-4271 for details of when each alias is preferred.

## A1

### ***Decrement Before variant***

Applies when P == 1 && U == 0 && W == 1.

VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <dreqlist>

**Increment After variant**

Applies when  $P == 0$  &&  $U == 1$ .

VSTM{<c>}{<q>}{.size} <Rn>{!}, <dreglist>  
VSTMIA{<c>}{<q>}{.size} <Rn>{!}, <dreglist>

**Decode for all variants of this encoding**

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FSTMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;

```

**CONSTRAINED UNPREDICTABLE** behavior

If  $\text{regs} == \emptyset$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If  $\text{regs} > 16 \mid \mid (\text{d+regs}) > 32$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

### Increment After variant

Applies when P == 0 && U == 1.

VSTM{<C>}{<q>}{.<size>} <Rn>{!}, <sreglist>  
VSTMIA{<C>}{<q>}{.<size>} <Rn>{!}, <sreglist>

### Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = TRUE; add = (U == '1'); wback = (W == '1'); d = UInt(Vd:D); n = UInt(Rn);
imm32 = ZeroExtend(imm8:'00', 32); regs = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;

```

### CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If (d+regs) > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

## T1

if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If `(d+regs) > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VSTM* on page K1-6113.

Related encodings: See *Advanced SIMD and floating-point 64-bit move* on page F3-2894 for the T32 instruction set, or *Advanced SIMD and floating-point 64-bit move* on page F4-2973 for the A32 instruction set.

### Alias conditions

Alias	is preferred when
<a href="#">VPUSH</a>	<code>P == '1' &amp;&amp; U == '0' &amp;&amp; W == '1' &amp;&amp; Rn == '1101'</code>

### Assembler symbols

<C>	See <i>Standard assembler syntax fields</i> on page F2-2848.
<q>	See <i>Standard assembler syntax fields</i> on page F2-2848.
<size>	An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. However, ARM deprecates use of the PC.
!	Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
<sreglist>	Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
<dreglist>	Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            MemA[address,4] = S[d+r]; address = address+4;
        else
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

## F6.1.226 VSTR

Store SIMD&FP register stores a single register from the Advanced SIMD and floating-point register file to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### Assembler symbols

<C>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
.64	Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
<Dd>	Is the 64-bit name of the SIMD&FP source register, encoded in the "D:Vd" field.
.32	Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
<Sd>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vd:D" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>
<imm>	For encoding A1 or T1: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2.

For encoding A1, T1: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    case esize of
        when 16
            MemA[address,2] = S[d]<15:0>;
        when 32
            MemA[address,4] = S[d];
        when 64
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d]<63:32> else D[d]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d]<31:0> else D[d]<63:32>;
```

## F6.1.227 VSUB (floating-point)

Vector Subtract (floating-point) subtracts the elements of one vector from the corresponding elements of another vector, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

#### 64-bit SIMD vector variant

Applies when Q == 0.

VSUB{<C>}{<Q>}.<dt> {<Dd>, }<Dn>, <Dm>

#### 128-bit SIMD vector variant

Applies when Q == 1.

VSUB{<C>}{<Q>}.<dt> {<Qd>, }<Qn>, <Qm>

#### Decode for all variants of this encoding

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

### Assembler symbols

<C> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values: I8           when size = 00 I16          when size = 01 I32          when size = 10 I64          when size = 11
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = Elem[D[n+r],e,esize] - Elem[D[m+r],e,esize];

```

## F6.1.229 VSUBHN

Vector Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are truncated. For rounded results, see [VRSUBHN](#).

There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

VSWP{<C>}{<q>}{.<dt>} <Dd>, <Dm>

#### 128-bit SIMD vector variant

Applies when Q == 1.

VSWP{<C>}{<q>}{.<dt>} <Qd>, <Qm>

#### Decode for all variants of this encoding

```
if size != '00' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

### Assembler symbols

<C> For encoding A1: see [Standard assembler syntax fields on page F2-2848](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2848](#).

<q> See [Standard assembler syntax fields on page F2-2848](#).

<dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>\*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>\*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

## Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
    if d == m then
        D[d+r] = bits(64) UNKNOWN;
    else
        D[d+r] = Din[m+r];
        D[m+r] = Din[d+r];
```

## F6.1.233 VTBL, VTBX

Vector Table Lookup uses byte indexes in a control vector to look up byte values in a table and generate a new vector. Indexes out of range return 0.

Vector Table Extension works in the same way, except that indexes out of range leave the destination element unchanged.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

### A1

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0
1	1	1	1	0	0	1	1	1	D	1	1	Vn	Vd	1	0	len	N	op	M	0	Vm				

#### VTBL variant

Applies when `op == 0`.

VTBL{<c>}{<q>}.8 <Dd>, <list>, <Dm>

#### VTBX variant

Applies when `op == 1`.

VTBX{<c>}{<q>}.8 <Dd>, <list>, <Dm>

#### Decode for all variants of this encoding

```
is_vtbl = (op == '0'); length = UInt(len)+1;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
if n+length > 32 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If `n + length > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

### T1

15	14	13	12	11	10	9	8	7	6	5	4	3	0		15	12		11	10	9	8	7	6	5	4	3	0	
1	1	1	1	1	1	1	1	1	D	1	1	Vn		Vd		1		0	len		N	op	M	0	Vm			

#### VTBL variant

Applies when `op == 0`.

VTBL{<c>}{<q>}.8 <Dd>, <list>, <Dm>

### VTBX variant

Applies when op == 1.

VTBX{<c>}{<q>}.8 <Dd>, <list>, <Dm>

### Decode for all variants of this encoding

```
is_vtbl = (op == '0'); length = UInt(len)+1;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
if n+length > 32 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If n + length > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

### Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler symbols

<c>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<list>	The vectors containing the table. It must be one of: {<Dn>} Encoded as len = 0b00. {<Dn>, <Dn+1>} Encoded as len = 0b01. {<Dn>, <Dn+1>, <Dn+2>} Encoded as len = 0b10. {<Dn>, <Dn+1>, <Dn+2>, <Dn+3>} Encoded as len = 0b11.
<Dm>	Is the 64-bit name of the SIMD&FP source register holding the indices, encoded in the "M:Vm" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();

    // Create 256-bit = 32-byte table variable, with zeros in entries that will not be used.
    table3 = if length == 4 then D[n+3] else Zeros(64);
    table2 = if length >= 3 then D[n+2] else Zeros(64);
    table1 = if length >= 2 then D[n+1] else Zeros(64);
    table = table3 : table2 : table1 : D[n];

    for i = 0 to 7
        index = UInt(Elem[D[m],i,8]);
        if index < 8*length then
            Elem[D[d],i,8] = Elem[table,index,8];
```

```
else
  if is_vtbl then
    Elem[D[d],i,8] = Zeros(8);
  // else Elem[D[d],i,8] unchanged
```

## F6.1.234 VTRN

Vector Transpose treats the elements of its operand vectors as elements of 2 x 2 matrices, and transposes the matrices.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows the operation of VTRN doubleword operations.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

This instruction is used by the pseudo-instructions [VUZP \(alias\)](#) and [VZIP \(alias\)](#). The pseudo-instruction is never the preferred disassembly.

if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

### Assembler symbols

<C>	For encoding A1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> . This encoding must be unconditional. For encoding T1: see <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<q>	See <a href="#">Standard assembler syntax fields on page F2-2848</a> .
<dt>	Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values: 8            when size = 00 16          when size = 01 32          when size = 10 The encoding size = 11 is reserved.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

### Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    h = elements DIV 2;

    for r = 0 to regs-1
        if d == m then
            D[d+r] = bits(64) UNKNOWN;
        else
            for e = 0 to h-1
                Elem[D[d+r],2*e+1,esize] = Elem[Din[m+r],2*e,esize];
                Elem[D[m+r],2*e,esize] = Elem[Din[d+r],2*e+1,esize];
```

## F6.1.235 VTST

Vector Test Bits takes each element in a vector, and bitwise ANDs it with the corresponding element of a second vector. If the result is not zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit fields.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

# Part G

## **The AArch32 System Level Architecture**

# Chapter G1

## The AArch32 System Level Programmers' Model

This chapter gives a system level description of the programmers' model for execution in AArch32 state. It contains the following sections:

- *About the AArch32 System level programmers' model* on page G1-4308.
- *Exception levels* on page G1-4309.
- *Exception terminology* on page G1-4310.
- *Execution state* on page G1-4312.
- *Instruction Set state* on page G1-4314.
- *Security state* on page G1-4315.
- *Security state, Exception levels, and AArch32 execution privilege* on page G1-4318.
- *Virtualization* on page G1-4320.
- *AArch32 PE modes, and general-purpose and Special-purpose registers* on page G1-4322.
- *Process state, PSTATE* on page G1-4332.
- *Instruction set states* on page G1-4338.
- *Handling exceptions that are taken to an Exception level using AArch32* on page G1-4340.
- *Exception return to an Exception level using AArch32* on page G1-4360.
- *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-4365.
- *AArch32 state exception descriptions* on page G1-4376.
- *Reset into AArch32 state* on page G1-4399.
- *Mechanisms for entering a low-power state* on page G1-4403.
- *The AArch32 System register interface* on page G1-4408.
- *Advanced SIMD and floating-point support* on page G1-4412.
- *Configurable instruction enables and disables, and trap controls* on page G1-4418.

## G1.1 About the AArch32 System level programmers' model

An application programmer has only a restricted view of the system. The System level programmers' model supports this application level view of the system, and includes features that are required for one or both of an operating system (OS) and a hypervisor to provide the programming environment seen by an application. This chapter describes the System level programmers' model when executing at EL1 or higher in an Exception level that is using AArch32.

The system level programmers' model includes all of the system features required to support operating systems and to handle hardware events.

The following sections give a system level introduction to the basic concepts of the ARM architecture AArch32 state, and the terminology that is used for describing the architecture when executing in this state:

- [Exception levels on page G1-4309](#).
- [Exception terminology on page G1-4310](#).
- [Execution state on page G1-4312](#).
- [Instruction Set state on page G1-4314](#).
- [Security state on page G1-4315](#).
- [Virtualization on page G1-4320](#).

The rest of this chapter describes the system level programmers' model when executing in AArch32 state.

The other chapters in this part describe:

- The memory system architecture, as seen when executing in an Exception level that is using AArch32:
  - [Chapter G3 The AArch32 System Level Memory Model](#) describes the general features of the ARMv8 memory model, when executing in AArch32 state, that are not visible at the application level.
  - **Note**  
[Chapter E2 The AArch32 Application Level Memory Model](#) describes the application level view of the memory model.
  - [Chapter G4 The AArch32 Virtual Memory System Architecture](#) describes the Virtual Memory System Architecture (VMSA) used in AArch32 state.
- The AArch32 System Registers, see [Chapter G6 AArch32 System Register Descriptions](#).

— **Note** —

The T32 and A32 instruction sets include instructions that provide system level functionality, such as returning from an exception. See for example, [ERET on page F5-3117](#).

## G1.2 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If EL $n$  is the Exception level, increased values of  $n$  indicate increased software execution privilege.
- Execution at EL0 is called *unprivileged execution*.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

### ———— Note ————

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

[The effect of implementation choices on the programmers' model on page D1-1899](#) provides information on implementations.

When executing in AArch32 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the *target Exception level* of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within *Security states*. [The ARMv8-A security model on page G1-4315](#) describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then because EL3 is only implemented in Secure state, execution at EL3 can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see [Chapter G4 The AArch32 Virtual Memory System Architecture](#).

### G1.2.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

<b>EL0</b>	Applications.
<b>EL1</b>	OS kernel and associated functions that are typically described as <i>privileged</i> .
<b>EL2</b>	Hypervisor.
<b>EL3</b>	Secure monitor.

## G1.3 Exception terminology

The following subsections define the terms that are used when describing exceptions:

- [Terminology for taking an exception.](#)
- [Terminology for returning from an exception.](#)
- [Exception levels.](#)
- [Definition of a precise exception.](#)
- [Definitions of synchronous and asynchronous exceptions on page G1-4311.](#)

### G1.3.1 Terminology for taking an exception

An exception is *generated* when the PE first responds to an exceptional condition. The PE state at this time is the state that the exception is *taken from*. The PE state immediately after taking the exception is the state that the exception is *taken to*.

### G1.3.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception *returns from*. The PE state immediately after the execution of that instruction is the state that the exception *returns to*.

### G1.3.3 Exception levels

An Exception level,  $EL_n$ , with a larger value of  $n$  than another Exception level, is described as being a *higher* Exception level than the other Exception level. For example,  $EL_3$  is a higher Exception level than  $EL_1$ .

An Exception level with a smaller value of  $n$  than another Exception level is described as being a *lower* Exception level than the other Exception level. For example,  $EL_0$  is a lower Exception level than  $EL_1$ .

An Exception level is described as:

- *Using AArch64* when execution in that Exception level is in the AArch64 Execution state.
- *Using AArch32* when execution in that Exception level is in the AArch32 Execution state.

### G1.3.4 Definition of a precise exception

An exception is described as *precise* when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the SError interrupt all exceptions that are taken to AArch32 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch32 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by those instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address that is used by the instruction.

In AArch32 state, examples of instructions that perform more than one single-copy atomic memory access are the LDM and STM instructions.

---

**Note**

- For the definition of a single-copy atomic access, see [Properties of single-copy atomic accesses on page E2-2759](#).
  - The SError interrupt replaces the ARMv7 asynchronous abort.
-

### G1.3.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about exceptions, see [Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340](#).

## G1.4 Execution state

The Execution states are:

**AArch64** The 64-bit Execution state.

**AArch32** The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

[Execution state on page A1-34](#) gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

---

**Note**

- [Typical Exception level usage model on page G1-4309](#) shows which Exception levels different software layers might typically use.
  - [The effect of implementation choices on the programmers' model on page D1-1899](#) gives information on supported configurations of Exception levels and Execution states.
- 

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. [Interprocessing on page D1-1887](#) describes this.

### G1.4.1 About the AArch32 PE modes

AArch32 state provides a set of *PE modes* that support normal software execution and handle exceptions. The current mode determines the set of registers that are available, as described in [AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-4327](#).

The AArch32 modes are:

- Monitor mode. This mode always executes at Secure EL3.
- Hyp mode. This mode always executes at Non-secure EL2.
- System, Supervisor, Abort, Undefined, IRQ and FIQ modes. The Exception level these modes execute at depends on the Security state, as described in [Security state on page G1-4315](#).
- User mode. This mode always executes at EL0.

---

**Note**

AArch64 state does not support modes. Modes are a concept that is specific to AArch32 state. Modes that execute at a particular Exception level are only implemented if that Exception level supports using AArch32.

---

For more information on modes see [AArch32 PE mode descriptions on page G1-4322](#).

The mode in use immediately before an exception is taken is described as the mode the exception is *taken from*. The mode that is used on taking the exception is described as the mode the exception is *taken to*.

All of the following define the mode that an exception is taken to:

- The type of exception.
- The mode the exception is taken from.
- Configuration settings defined at EL2 and EL3.

Monitor mode and Hyp mode can create system traps that cause exceptions to EL3 or EL2 respectively. There is an architected hierarchy where EL2 and EL3 configuration settings affect a common condition, for example interrupt routing. When no traps are enabled for a particular condition, the AArch32 mode an exception is taken to is called the *default mode* for that exception.

In AArch32 state, a number of different modes can exist at the same Exception level. All modes at a particular Exception level have the *execution privilege*, meaning they have the same access rights for accesses to memory and to System registers. However, the mapping of PE modes to Exception levels depends on the Security state, as described in [Security state on page G1-4315](#). [Security state, Exception levels, and AArch32 execution privilege on page G1-4318](#) gives more information about the PE modes, their associated execution privilege, and how this maps onto the Exception levels.

## G1.5 Instruction Set state

In AArch32 state, the *Instruction Set state* determines the instruction set that the PE is executing. In an implementation that follows the ARM recommendations, the available Instruction Set states are:

**T32 state**      The PE is executing T32 instructions.

**A32 state**      The PE is executing A32 instructions.

---

**Note**

In previous versions of the ARM architecture:

- The T32 instruction set was called the Thumb instruction set.
  - The A32 instruction set was called the ARM instruction set.
- 

For more information, see [Process state, PSTATE](#) on page E1-2734.

## G1.6 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

<b>Secure state</b>	When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.
<b>Non-secure state</b>	When in this state, the PE: <ul style="list-style-type: none"> <li>• Can access only the Non-secure physical address space.</li> <li>• Cannot access the Secure system control resources.</li> </ul>

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see [About VMSAv8-32 on page G4-4558](#).

### G1.6.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If EL2 is implemented, it exists only in Non-secure state.
- If the implementation does not include EL3 it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
  - Non-secure state if the implementation includes EL2.

### The AArch32 security model, and execution privilege

The Exception level hierarchy of four Exception levels, EL0, EL1, EL2, and EL3, applies to execution in both Execution states. This section describes the mapping between Exception levels, AArch32 modes, and execution privilege.

The AArch32 modes Monitor, System, Supervisor, Abort, Undefined, IRQ, and FIQ all have the same execution privilege.

In Secure state:

- Monitor mode executes only at EL3, and is accessible only when EL3 is using AArch32.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode all:
  - Execute at EL1 when EL3 is using AArch64.
  - Execute at EL3 when EL3 is using AArch32.

This means that there is a difference in the Secure state hierarchy that the PE is using, depending on which Execution state EL3 is using:

- If EL3 is using AArch64:
  - There is no support for Monitor mode.
  - If EL1 is using AArch32, System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL1.
- If EL3 is using AArch32:
  - Monitor mode is supported, and executes at Secure EL3
  - System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL3.
  - There is no support for a Secure EL1 Exception level.

See [Security behavior in Exception levels using AArch32 when EL3 is using AArch64 on page G1-4352](#) for more information about operation in a Secure EL1 mode when EL3 is using AArch64.

In Non-secure state, the PL1 modes System, Supervisor, Abort, Undefined, IRQ, and FIQ always execute at EL1.

User mode always executes at EL0 and has the lowest possible execution privilege.

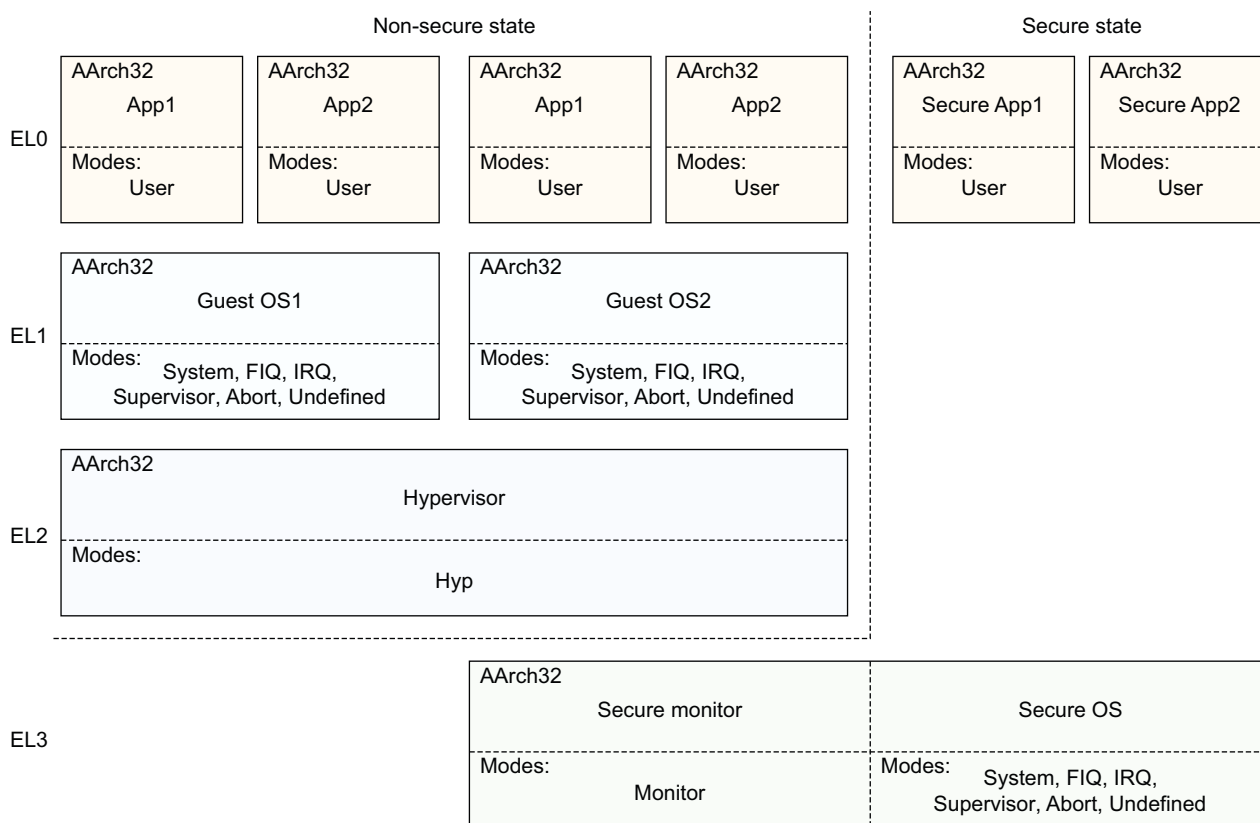

Hyp mode always executes in Non-secure state at EL2 and has higher execution privilege than all of:

- User mode.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode.

[Limited use of Privilege level in ARMv8 AArch32 state on page G1-4319](#) describes how, in some contexts, the concept of *Privilege levels* can be used to represent the execution privilege hierarchy.

For more information about the modes see [About the AArch32 PE modes on page G1-4312](#).

**Figure G1-1** shows the security model when EL3 is using AArch32, and shows the expected use of the different Exception levels, and which modes execute at which Exception levels.

**Figure G1-1 ARMv8-A Security model when EL3 is using AArch32**

**Note**

For an overview of the Security models when EL3 is using AArch64:

- See [Figure G1-2 on page G1-4325](#) for the case where EL2, EL1, and EL0 are all using AArch32. This figure shows the implementation of the PE modes.
- See [Figure D1-1 on page D1-1781](#) for an overview of the set of possible implementations.

Figure G1-1 on page G1-4316 shows that when EL3 is using AArch32, the Exception levels and modes available in each Security state are as follows:

#### Secure state

<b>EL0</b>	User mode.
<b>EL3</b>	Any mode that is available in Secure state, other than User mode.

#### Non-secure state

<b>EL0</b>	User mode.
<b>EL1</b>	Any mode that is available in Non-secure state, other than Hyp mode and User mode.
<b>EL2</b>	Hyp mode.

Execution at EL0 is described as *unprivileged execution*.

A mode associated with a particular Exception level, EL $n$ , is described as an EL $n$  mode.

#### ———— Note ————

The Exception level defines the ability to access resources in the current Security state, and does not imply anything about the ability to access resources in the other Security state.

When EL3 is using AArch32, many AArch32 System registers accessible at PL1 are *banked* between the Secure and Non-secure states.

When EL3 is using AArch64 and Secure EL1 is using AArch32, System registers accessible at PL1 are not banked between the Non-secure and Secure states. Software running at EL3 is expected to switch the content of the PL1-accessible System registers between the Secure and Non-secure context, in a similar manner to switching the contents of general purpose registers. For information on the relationship between AArch64 and AArch32 System registers in an interprocessing environment, see [Mapping of the System registers between the Execution states on page D1-1890](#).

For more information on the System registers, see [The AArch32 System register interface on page G1-4408](#).

The *Secure Monitor Call* (SMC) instruction provides software with a system call to EL3. When executing at a privileged Exception level, SMC instructions generates exceptions. For more information, see [Secure Monitor Call \(SMC\) exception on page G1-4382](#) and [SMC on page F5-3429](#).

#### ———— Note ————

For more information about the Privilege level terminology, see [Security state, Exception levels, and AArch32 execution privilege on page G1-4318](#).

## Changing from Secure state to Non-secure state

Monitor mode is provided to support switching between Secure and Non-secure states. When executing in an Exception level that is using AArch32, except in Monitor mode and Hyp mode, the Security state is controlled:

- By the [SCR.NS](#) bit, when EL3 is using AArch32.
- By the [SCR\\_EL3.NS](#) bit, when EL3 is using AArch64.

The mapping of AArch32 privileged modes to the exception hierarchy means that it is possible when EL3 is using AArch32 to change from EL3 to Non-secure EL1 without an exception return. This can occur in one of the following ways:

- Using an MSR or CPS instruction to switch from Monitor mode to another privileged mode while [SCR.NS](#) is 1.
- Using an MCR instruction that writes [SCR.NS](#) to change from Secure to Non-secure state when in a privileged mode other than Monitor mode.

ARM strongly recommends that software executing at EL3 using AArch32 does not use either of these mechanisms to change from EL3 to Non-secure EL1 without an exception return. The use of both of these mechanisms is deprecated.

## G1.7 Security state, Exception levels, and AArch32 execution privilege

In ARMv8, the hierarchy of software execution privilege, within a particular Security state, is defined by the Exception levels, with higher Exception level numbers indicating higher privilege. [Table G1-1](#) shows this hierarchy for each Security state.

**Table G1-1 Execution privilege and Exception levels, by Security state**

Execution privilege	Secure state	Non-secure state	Typical use
Highest	EL3	– <sup>a</sup>	Secure monitor
-	– <sup>a</sup>	EL2	Hypervisor
-	EL1	EL1	Secure or Non-secure OS
Lowest, Unprivileged	EL0	EL0	Secure or Non-secure application

a. EL2 is never implemented in Secure state, and EL3 is never implemented in Non-secure state.

When executing in AArch32 state, within a given Security state, the current PE state, including the execution privilege, is primarily indicated by the current *PE mode*. In Secure state, how the PE modes map onto the Exception levels depends on whether EL3 is using AArch32 or is using AArch64, and:

- [Figure G1-1 on page G1-4316](#) shows this mapping when EL3 is using AArch32.
- [Figure G1-2 on page G1-4325](#) shows this mapping when EL3 is using AArch64.

[Table G1-2](#) shows this mapping. In interpreting this table:

- Monitor mode is implemented only in Secure state, and only if EL3 is using AArch32.
- Hyp mode is implemented only in Non-secure state, and only if EL2 is using AArch32.
- System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented:
  - In Secure state** If either:
    - EL3 is using AArch32.
    - EL3 is using AArch64 and EL1 is using AArch32.
  - In Non-secure state** If EL1 is using AArch32.
- User mode is implemented if EL0 is using AArch32.

**Table G1-2 Mapping of AArch32 PE modes to Exception levels**

Exception level	PE modes in the given Security state, and EL3 Execution state		
	Secure state, EL3 using AArch32	Secure state, EL3 using AArch64	Non-secure state
EL3	Monitor, System, FIQ, IRQ, Supervisor, Abort, Undefined	-	-
EL2	-	-	Hyp
EL1	-	System, FIQ, IRQ, Supervisor, Abort, Undefined	System, FIQ, IRQ, Supervisor, Abort, Undefined
EL0	User	User	User

Because AArch32 behavior is described in terms of the PE modes, and transitions between PE modes, the Exception levels are implicit in most of the description of operation in AArch32 state.

## G1.7.1 Limited use of Privilege level in ARMv8 AArch32 state

As described in *The VMSAv8-32 translation regimes on page G4-4560*, a *translation regime* maps a virtual address (VA) to the corresponding physical address (PA). The VMSAv8-64 translation regimes are defined by the Exception levels that use them. However, because the mapping between PE modes and Exception levels in Secure state depends on whether EL3 is using AArch32 or is using AArch64, as shown in *Table G1-2 on page G1-4318*, the VMSAv8-32 translation regimes cannot be described simply in terms of either the Exception levels or the PE modes that use them.

To provide a consistent description of address translation as seen from AArch32 state, the VMSAv8-32 translation regimes are described in terms of the *Privilege levels* originally defined in the ARMv7 descriptions of AArch32 state. *Table G1-3* shows how the PE modes map to these Privilege levels:

**Table G1-3 Mapping of PE modes to AArch32 Privilege levels**

Privilege level	Secure state	Non-secure state
PL2	-	Hyp <sup>a</sup>
PL1	Monitor <sup>b</sup> , System, FIQ, IRQ, Supervisor, Abort, Undefined	System, FIQ, IRQ, Supervisor, Abort, Undefined
PL0	User	User

- a. Implemented only in Non-secure state, and only if EL2 is using AArch32
- b. Implemented only in Secure state, and only if EL3 is using AArch32.

Comparing *Table G1-3* with *Table G1-2 on page G1-4318* shows that:

### In Non-secure state

Each privilege level maps to the corresponding Exception level. For example PL1 maps to EL1.

### In Secure state

PL0 maps to EL0.

The mapping of PL1 depends on the Execution state being used by EL3, as follows:

**EL3 using AArch64** Secure PL1 maps to Secure EL1. Monitor mode is not implemented.

**EL3 using AArch32** Secure PL1 maps to Secure EL3. Monitor mode is implemented as one of the Secure PL1 modes.

## G1.8 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2. A PE is in *Hyp mode* when it is executing at EL2 in the AArch32 state. An exception return from Hyp mode to software running at EL1 or EL0 is performed using the ERET instruction.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between *virtual machines*. A virtual machine is comprised of Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems, that each run in Non-secure EL1, on a virtual machine.
- For each Guest operating system, applications, that usually run in Non-secure EL0, on a virtual machine.

---

### Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

---

The hypervisor assigns a *virtual machine identifier* (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- *Trap* various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2.
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

In Non-secure state:

- The implementation provides an independent *translation regime* for memory accesses from EL2.
- For the PL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the *virtual address* (VA) to an *intermediate physical address* (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the *physical address* (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see [Chapter G4 The AArch32 Virtual Memory System Architecture](#).

### G1.8.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. [EL2 configurable controls on page G1-4427](#), describes these.
- All of the virtual interrupts:
  - Virtual SError.
  - Virtual IRQ.
  - Virtual FIQ.

HVC exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See [Virtual interrupts](#).

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3. For more information, see [Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365](#).

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information see:
  - [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356](#).
  - [Routing debug exceptions to EL2 using AArch32 on page G1-4358](#).
- Provides mechanisms to trap PE operations to EL2. See [EL2 configurable controls on page G1-4427](#).  
When an operation is trapped to EL2, the hypervisor typically either:
  - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
  - Returns an error to the Guest OS.

## Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in [Table G1-4](#).

**Table G1-4 The virtual interrupts**

Physical interrupt	Corresponding virtual interrupt
External SError	Virtual SError
IRQ	Virtual IRQ
FIQ	Virtual FIQ

Software executing at EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. [Example G1-1](#) shows a usage model for virtual interrupts.

### Example G1-1 Virtual interrupt usage model

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.
2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
  - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
  - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

Non-secure EL1 and Non-secure EL0 modes cannot distinguish a virtual interrupt from the corresponding physical interrupt.

For more information see [Virtual exceptions when an implementation includes EL2 on page G1-4365](#).

## G1.9 AArch32 PE modes, and general-purpose and Special-purpose registers

The following sections describe the AArch32 PE modes and the general-purpose registers and the PC:

- [AArch32 PE mode descriptions](#).
- [AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-4327](#).
- [Saved Program Status Registers \(SPSRs\) on page G1-4329](#).
- [ELR\\_hyp on page G1-4331](#).

### ———— Note ————

The PC is included in the scope of this section because, in AArch32 state, it is defined as being part of the same register file as the general-purpose registers. That is, the AArch32 register file R0-R15 comprises:

- The general-purpose registers R0-R14.
- The PC, that can be described as R15.

### G1.9.1 AArch32 PE mode descriptions

[Table G1-5](#) shows the PE modes defined by the ARM architecture, for execution in AArch32 state. In this table:

- The *PE mode* column gives the name of each mode and the abbreviation used, for example, in the general-purpose register name suffixes used in [AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-4327](#).
- The *Encoding* column gives the corresponding `PSTATE.M` field.
- The *Exception level* column gives the Exception level at which the mode is implemented, including dependencies on the current Security state and on whether EL3 is using AArch32, see [Exception levels on page G1-4309](#).

**Table G1-5 AArch32 PE modes**

PE mode		Encoding	Security state	Exception level	Implemented
User	usr	10000	Both	EL0	Always
FIQ	fiq	10001	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
IRQ	irq	10010	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
Supervisor	svc	10011	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
Monitor	mon	10110	Secure	EL3	If EL3 implemented and using AArch32
Abort	abc	10111	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
Hyp	hyp	11010	Non-secure	EL2	If EL2 implemented and using AArch32
Undefined	und	11011	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
System	sys	11111	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always

a. EL3 if EL3 is using AArch32. EL1 if EL3 is using AArch64 and EL1 is using AArch32.

Mode changes can be made under software control, or can be caused by an external or internal exception.

## Notes on the AArch32 PE modes

PE modes are defined only in AArch32 state. Because each mode is implemented as part of a particular Exception level that is using AArch32, the set of available modes depends on which Exception levels are implemented and using AArch32, as described in [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325](#).

This section gives more information about each of the modes, when it is implemented.

**User mode** Software executing in User mode executes at EL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:

- Makes only unprivileged accesses to system resources, meaning it cannot access protected system resources.
- Makes only unprivileged access to memory.
- Cannot change mode except by causing an exception, see [Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340](#).

**System mode** System mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325](#).

System mode has the same registers available as User mode, and is not entered by any exception.

### Supervisor mode

Supervisor mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325](#).

Supervisor mode is the default mode to which a Supervisor Call exception is taken. Executing a SVC (Supervisor Call) instruction generates a Supervisor Call exception.

In an implementation where the highest implemented Exception level is using AArch32, if that Exception level is EL3 or EL1, a PE enters Supervisor mode on Reset.

**Abort mode** Abort mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325](#).

Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

### Undefined mode

Undefined mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325](#).

Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

**FIQ mode** FIQ mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325](#).

FIQ mode is the default mode to which an FIQ interrupt is taken.

**IRQ mode** IRQ mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-4325](#).

IRQ mode is the default mode to which an IRQ interrupt is taken.

**Hyp mode** Hyp mode is the Non-secure EL2 mode.

Hyp mode is entered on taking an exception from Non-secure state that must be taken to EL2.

In an implementation where the highest implemented Exception level is EL2 and EL2 uses AArch32 on reset, a PE enters Hyp mode on Reset.

The Hypervisor Call exception and Hyp Trap exception are implemented as part of EL2 and are always taken to Hyp mode.

---

**Note**

---

This means that Hypervisor Call and Hyp Trap exceptions cannot be taken from Secure state.

---

When the value of the Hypervisor Call enable bit, [SCR.HCE](#), is 1, executing an HVC (Hypervisor Call) instruction in a Non-secure EL1 mode generates a Hypervisor Call exception.

For more information, see [Hyp mode on page G1-4326](#).

### Monitor mode

Monitor mode is the Secure EL3 mode. This means it is always in the Secure state, regardless of the value of the [SCR.NS](#) bit.

Monitor mode is the mode to which a Secure Monitor Call exception is taken. In a Non-secure EL1 mode, or a Secure EL3 mode, executing an SMC (Secure Monitor Call) instruction generates a Secure Monitor Call exception.

When EL3 is using AArch32, some exceptions that are taken to a different mode by default can be configured to be taken to EL3, see [PE mode for taking exceptions on page G1-4350](#).

When EL3 is using AArch32, software executing in Monitor mode:

- Has access to both the Secure and Non-secure copies of System registers.
- Can perform an exception return to Secure state, or to Non-secure state.

This means that, when EL3 is using AArch32, Monitor mode provides the only recommended method of changing between the Secure and Non-secure Security states.

### Secure and Non-secure modes

In an implementation that includes EL3, the names of most implemented modes can be qualified as Secure or Non-secure, to indicate whether the PE is also in Secure state or Non-secure state. For example:

- If a PE is in Supervisor mode and Secure state, it is in *Secure Supervisor mode*.
- If a PE is in User mode and Non-secure state, it is in *Non-secure User mode*.

---

**Note**

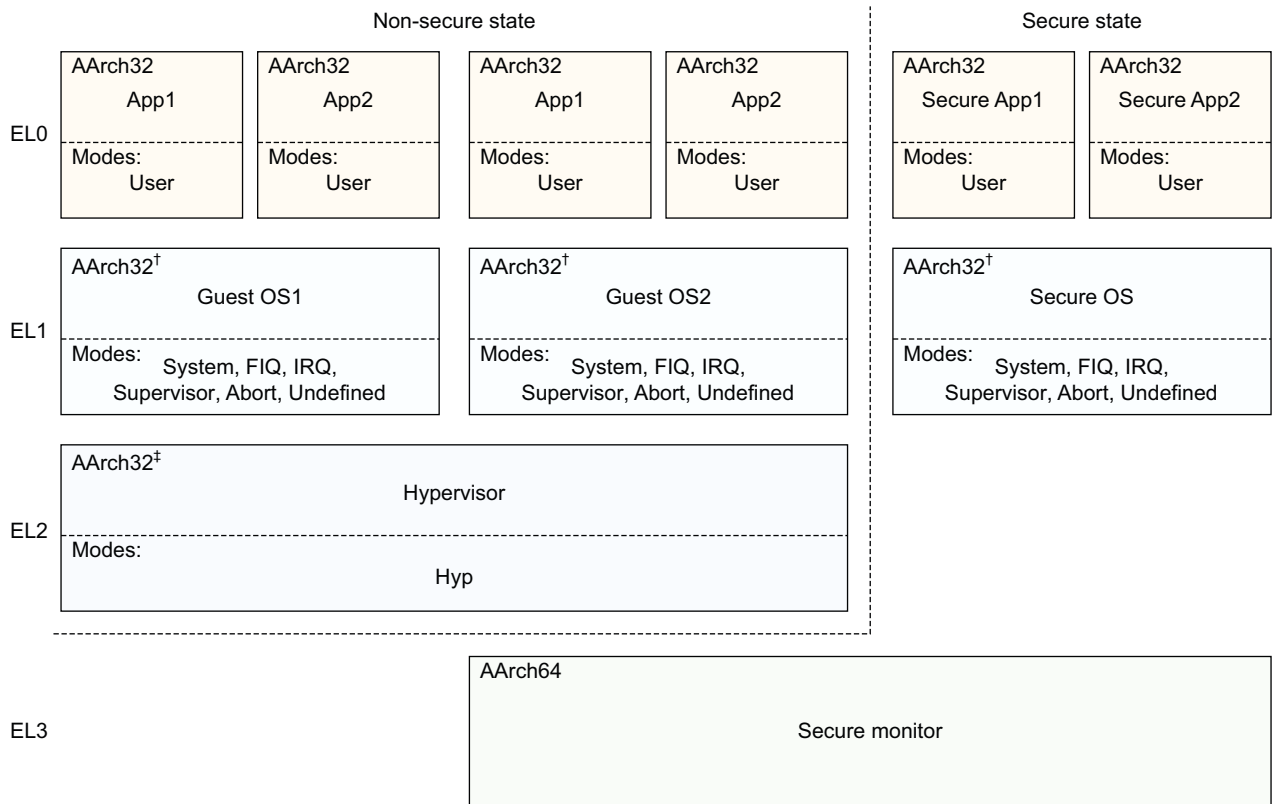

---

As indicated in the appropriate Mode descriptions:

- Monitor mode is a Secure mode, meaning it is always in the Secure state.
  - Hyp mode is a Non-secure mode, meaning it is accessible only in Non-secure state.
-

### Effect of the EL3 Execution state on the PE modes and Exception levels

Figure G1-1 on page G1-4316 shows the PE modes, Exception levels, and Security states, for an implementation that includes all of the Exception levels, when EL3 is using AArch32. Figure G1-2 shows how the implemented modes change when EL3 is using AArch64.

<sup>†</sup> When EL1 is using AArch64, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are not implemented

<sup>‡</sup> When EL2 is using AArch64, Hyp mode is not implemented

**Figure G1-2 ARMv8 Exception levels, and PE modes, when EL3 is using AArch64**

Comparing Figure G1-1 on page G1-4316 and Figure G1-2 shows how, in Secure state only, the implementation of System, FIQ, IRQ, Supervisor, Abort, and Undefined mode depends on the Execution state that EL3 is using. That is, these modes are implemented as follows:

#### Non-secure state

If Non-secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Non-secure state.

**Secure state** The implementation of these modes depends on the Execution state that EL3 is using, as follows:

**EL3 using AArch64** If Secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Secure state.

**EL3 using AArch32** In Secure state, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL3, see Figure G1-1 on page G1-4316.

## Hyp mode

Hyp mode is the Non-secure EL2 mode. When EL2 is using AArch32, it provides the usual method of controlling the virtualization of Non-secure execution at EL1 and EL0.

---

### Note

The alternative method of controlling this functionality is by accessing the EL2 controls from EL3 with the [SCR\\_EL3.NS](#) or [SCR.NS](#) bit set to 1.

---

This section summarizes how Hyp mode differs from the other modes, and references where this part of the manual describes the features of Hyp mode in more detail:

- Software executing in Hyp mode executes at EL2, see [Figure G1-1 on page G1-4316](#).
- Hyp mode is accessible only in Non-secure state. In Secure state, an attempt by a CPS or an MSR instruction to change [PSTATE.M](#) to Hyp mode is an illegal change to [PSTATE.M](#), as described in [Illegal changes to PSTATE.M on page G1-4336](#).
- In Non-debug state, the only mechanisms for changing to Hyp mode are:
  - An exception taken from a Non-secure EL1 or EL0 mode.
  - When EL3 is using AArch32, an exception return from Secure Monitor mode.
  - When EL3 is using AArch64, an exception return from EL3.
- In Hyp mode, the only exception return is execution of an ERET instruction, see [ERET on page F5-3117](#).
- In Hyp mode, the [CPACR](#) has no effect on the execution of;
  - System register access instructions.
  - Advanced SIMD and floating-point instructions.The [HCPTR](#) controls execution of these instructions in Hyp mode.
- If software running in Hyp mode executes an SVC instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see [SVC on page F5-3575](#).
- An exception return with restored [PSTATE](#) specifying Hyp mode is an *illegal return event*, as described in [Illegal return events from AArch32 state on page G1-4361](#), if any of the following applies:
  - EL3 is using AArch64 and the value of [SCR\\_EL3.NS](#) is 0.
  - EL3 is using AArch32 and the value of [SCR.NS](#) is 0.
  - The return is from a Non-secure EL1 mode.
- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
  - SRS. See [SRS, SRSDA, SRSDDB, SRSIA, SRSIB on page F5-3464](#).
  - RFE. See [RFE, RFEDA, RFEDB, RFEIA, RFEIB on page F5-3363](#).
  - [LDM \(exception return\) on page F5-3148](#).
  - [LDM \(User registers\) on page F5-3150](#).
  - [STM \(User registers\) on page F5-3499](#).
  - The SUBS PC, LR forms of the instructions described in [SUB, SUBS \(immediate\) on page F5-3560](#).

---

### Note

In T32 state, ERET is encoded as SUBS PC, LR, #0, and therefore this is a valid instruction.

---

- The exception return form of the instructions described in [MOV, MOVS \(register\) on page F5-3260](#).

In addition, deprecated forms of the A32 ADCS, ADDS, ANDS, BICS, EORS, MOVs, MVNS, ORRS, RSBS, RSCS, SBCS, and SUBS instructions with the PC as the destination register are UNDEFINED if executed in Hyp mode. The instruction descriptions identify these UNDEFINED cases.

- The Load unprivileged and Store unprivileged instructions LDRT, LDRSHT, LDRHT, LDRBT, STRT, STRHT, and STRBT, are CONSTRAINED UNPREDICTABLE if executed in Hyp mode, see [Execution of Load/Store unprivileged instructions in Hyp mode on page K1-6115](#).

In an implementation that includes EL3, from reset, the HVC instruction is UNDEFINED in Non-secure EL1 modes, meaning entry to Hyp mode is disabled by default. To permit entry to Hyp mode using the Hypervisor Call exception, Secure software must enable use of the HVC instruction:

- By setting the [SCR\\_EL3.HCE](#) bit to 1, if EL3 is using AArch64.
- By setting the [SCR.HCE](#) bit to 1, if EL3 is using AArch32.

When the HVC instruction is UNDEFINED in Non-secure EL1 modes because of the value of the [SCR\\_EL3.HCE](#) or [SCR.HCE](#) bit, HVC is CONSTRAINED UNPREDICTABLE in Hyp mode.

### Pseudocode description of mode operations

The [BadMode\(\)](#) function tests whether a 5-bit mode number corresponds to one of the permitted modes.

The [BadMode\(\)](#) function is defined in [Chapter J1 ARMv8 Pseudocode](#).

## G1.9.2 AArch32 general-purpose registers, the PC, and the Special-purpose registers

[The general-purpose registers, and the PC, in AArch32 state on page E1-2731](#) describes the application level view of the general-purpose registers, and the PC. This view provides:

- The general-purpose registers R0-R14, of which:
  - The preferred name for R13 is SP (*stack pointer*).
  - The preferred name for R14 is LR (*link register*).
- The PC (*program counter*), that can be described as R15.

These registers are selected from a larger set of registers, that includes *Banked* copies of some registers, with the current register selected by the execution mode. The implementation and banking of the general-purpose registers depends on whether or not the implementation includes EL2 and EL3, and whether those Exception levels are using AArch32. [Figure G1-3 on page G1-4328](#) shows the full set of Banked general-purpose registers, and the Special-purpose registers:

- The Program Status Registers [CPSR](#) and [SPSR](#).
- [ELR\\_hyp](#).

#### ————— Note —————

The architecture uses system level register names, such as R0\_usr, R8\_usr, and R8\_fiq, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.

Application level view		System level view								
	User	System	Hyp <sup>†</sup>	Supervisor	Abort	Undefined	Monitor <sup>‡</sup>	IRQ	FIQ	
R0	R0_usr									
R1	R1_usr									
R2	R2_usr									
R3	R3_usr									
R4	R4_usr									
R5	R5_usr									
R6	R6_usr									
R7	R7_usr									
R8	R8_usr								R8_fiq	
R9	R9_usr								R9_fiq	
R10	R10_usr								R10_fiq	
R11	R11_usr								R11_fiq	
R12	R12_usr								R12_fiq	
SP	SP_usr		SP_hyp	SP_svc	SP_abt	SP_und	SP_mon	SP_irq	SP_fiq	
LR	LR_usr			LR_svc	LR_abt	LR_und	LR_mon	LR_irq	LR_fiq	
PC	PC									
APSR	CPSR									
			SPSR_hyp	SPSR_svc	SPSR_abt	SPSR_und	SPSR_mon	SPSR_irq	SPSR_fiq	
			ELR_hyp							

‡ Part of EL3. Exists only in Secure state, and only when EL3 is using AArch32.

† Part of EL2. Exists only in Non-secure state, and only when EL2 is using AArch32.

Cells with no entry indicate that the User mode register is used.

**Figure G1-3 AArch32 general-purpose registers, PC, and Special-purpose registers, showing banking**

As described in *PE mode for taking exceptions* on page G1-4350, on taking an exception the PE changes mode, unless it is already in the mode to which it must take the exception. Each mode that the PE might enter in this way has:

- A Banked copy of the stack pointer, for example SP\_irq and SP\_hyp.
- A register that holds a preferred return address for the exception. This is:
  - For the EL2 mode, Hyp mode, the Special-purpose register [ELR\\_hyp](#).
  - For the other privileged modes to which exceptions can be taken, a Banked copy of the link register, for example LR\_und and LR\_mon.
- A saved copy of [PSTATE](#), made on exception entry, for example SPSR\_irq and SPSR\_hyp.

In addition FIQ mode has Banked copies of the general-purpose registers R8 to R12.

User mode and System mode share the same general-purpose registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see *The general-purpose registers, and the PC, in AArch32 state* on page E1-2731.

## AArch32 Special-purpose registers

In AArch32 state, the Special-purpose registers are:

- The [CPSR](#) and its view as the [APSR](#).
- The [SPSR](#), including the banked copies [SPSR\\_abt](#), [SPSR\\_fiq](#), [SPSR\\_hyp](#), [SPSR\\_irq](#), [SPSR\\_mon](#), [SPSR\\_svc](#), and [SPSR\\_und](#).
- The [ELR\\_hyp](#).

## Pseudocode description of general-purpose register and PC operations

The following pseudocode gives access to the general-purpose registers and the PC. These registers are an array, `_R[]`, indexed by parameter `n`. This array is common to AArch32 and AArch64 operation and therefore contains 31 64-bit registers. `_PC` is the program counter, and its definition is common to AArch32 and AArch64 operation and therefore its size is 64-bit.

`LookUpRIndex()` looks up the index value, `n`, for the specified register number and PE mode, using `RBankSelect()` to evaluates the result.

`R[]` accesses the specified general-purpose register in the current PE mode, using `Rmode[]` to access the register, accessing `_R[]` if necessary. `SP` accesses the stack pointer, `LR` accesses the link register, and `PC` accesses the program counter. Each function has a non-assignment form for register reads and an assignment form for register writes, other than `PC`, which has only a non-assignment form.

`BranchTo()` performs a branch to the specified address.

The `_R[]`, `_PC`, `LR`, `SP`, `LookUpRIndex()`, `RBankSelect()`, `Rmode[]`, and `BranchTo()` functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

### G1.9.3 Saved Program Status Registers (SPSRs)

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions. In AArch32 state, there is an SPSR for every mode that an exception can be taken to, as shown in [Figure G1-3 on page G1-4328](#). For example, the SPSR for Monitor mode is called `SPSR_mon`.

#### ———— Note ————

Exceptions cannot be taken to EL0.

When the PE takes an exception, PE state is saved from `PSTATE` in the SPSR for the mode the exception is taken to. For example, if the PE takes an exception to Monitor mode, PE state is saved in `SPSR_mon`. For more information on `PSTATE`, see [Process state, PSTATE on page G1-4332](#).

#### ———— Note ————

All `PSTATE` fields are saved, including those which have no direct read and write access.

Saving the `PSTATE` fields means the exception handler can:

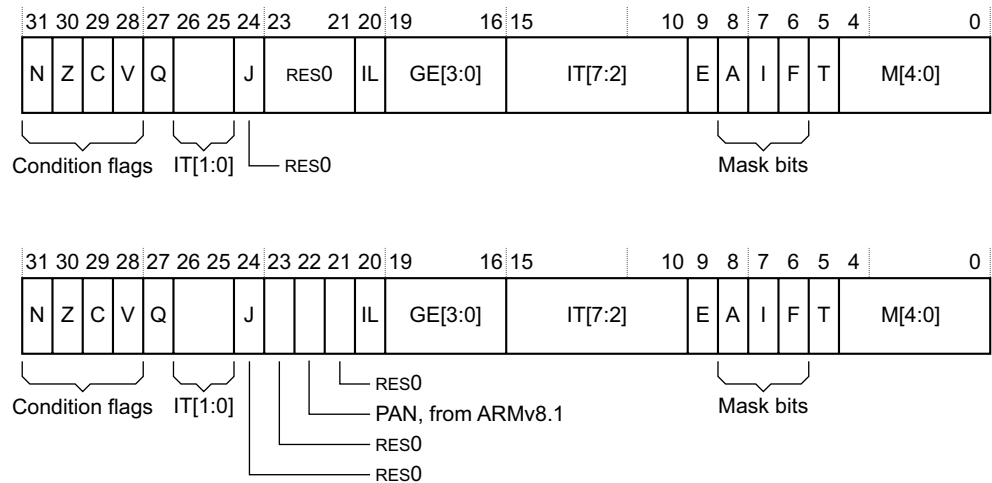

- On return from the exception, restore the PE state to the values it had immediately before the exception was taken. When the PE returns from an exception, PE state is restored to the state stored in the SPSR of the mode the exception is returning from, if the exception return is made using one of:
  - `ERET`.
  - `LDM`.
  - The Exception return form of the instruction described in [MOV, MOVS \(register\) on page F5-3260](#).
  - The Exception return form of the instruction described in [SUB, SUBS \(immediate\) on page F5-3560](#).

For example, on returning from Monitor mode, PE state is restored to the state stored in `SPSR_mon`. If the exception return is made using the `RFE` instruction, the PE restores the PE state from an SPSR valued read from memory.
- Examine the value that `PSTATE` had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

The SPSRs are UNKNOWN on reset. Any operation in a Non-secure EL1 or EL0 mode makes `SPSR_hyp` UNKNOWN.

## SPSR format for exceptions taken to AArch32 state

The SPSR bit assignments are:

### N, Z, C, V, Q, GE[3:0], bits[31:27, 19:16]

Shows the value of the [PSTATE](#). {N, Z, C, V, Q, GE} flags immediately before the exception was taken.

### IT[1:0], J, IL, IT[7:2], E, T, bits[26:24, 20, 15:9, 5]

Shows the values of the [PSTATE](#). {IT[7:0], J, IL, E, T} PE state controls immediately before the exception was taken. The J bit is RES0.

**Bit[23]** Reserved, RES0.

**Bit[22]** In ARMv8.0, RES0.

In ARMv8.1, PAN. Shows the value of the [PSTATE](#).PAN state bit immediately before the exception was taken.

**Bit[21]** Reserved, RES0.

### A, I, F, M, bits[8:6, 4:0]

Shows the values of the [PSTATE](#). {A, I, F} exception mask and [PSTATE](#).M mode bits immediately before the exception was taken.

SPSR bits that are defined as RES0 on an exception taken from AArch32 state are ignored on any exception return to AArch32 state.

## Pseudocode description of SPSR operations

The following pseudocode gives access to the SPSRs.

The [SPSR\[\]](#) function accesses the current SPSR and is common to AArch32 and AArch64 operation.

The [SPSRWriteByInstr\(\)](#) function is used by the [MSR \(register\)](#) and [MSR \(immediate\)](#) instructions to update the current SPSR.

The [SPSR\[\]](#) and [SPSRWriteByInstr\(\)](#) functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

## G1.9.4 ELR\_hyp

Hyp mode does not provide its own Banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred return address is stored in ELR\_hyp, a 32-bit Special-purpose register implemented for this purpose.

ELR\_hyp can be accessed explicitly only by executing:

- An MRS or MSR instruction that targets ELR\_hyp, see:
  - [MRS \(Banked register\) on page F5-3277](#).
  - [MSR \(Banked register\) on page F5-3281](#).

The ERET instruction uses the value in ELR\_hyp as the return address for the exception. For more information, see [ERET on page F5-3117](#).

Software execution in any Non-secure EL1 or EL0 mode makes ELR\_hyp UNKNOWN.

## G1.10 Process state, PSTATE

In the ARMv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:

- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type [ProcState](#). [ProcState](#) is defined in [Chapter J1 ARMv8 Pseudocode](#).

The PSTATE fields that are meaningful in AArch32 state are:

### The Condition flags

<b>N</b>	Negative Condition flag.
<b>Z</b>	Zero Condition flag.
<b>C</b>	Carry Condition flag.
<b>V</b>	Overflow Condition flag.

[Process state, PSTATE on page E1-2734](#) gives more information about these.

### The overflow or saturation flag

<b>Q</b>	See <a href="#">Process state, PSTATE on page E1-2734</a> .
----------	---

### The greater than or equal flags

<b>GE[3:0]</b>	See <a href="#">Process state, PSTATE on page E1-2734</a> .
----------------	---

### The PE state controls

<b>J, T</b>	Instruction set state. See <a href="#">Process state, PSTATE on page E1-2734</a> . J is RES0. On a reset to AArch32 state, T is set to an IMPLEMENTATION DEFINED value. On taking an exception to: <ul style="list-style-type: none"> <li>• A PL1 mode using AArch32, T is set to <a href="#">SCTLR.TE</a>.</li> <li>• EL2 using AArch32, T is set to <a href="#">HSCTLR.TE</a>.</li> </ul>
<b>IT[7:0]</b>	IT block state bits. See <a href="#">Process state, PSTATE on page E1-2734</a> . On a reset or taking an exception to AArch32 state, these bits are set to 0.
<b>E</b>	Endianness of data accesses. See <a href="#">Process state, PSTATE on page E1-2734</a> . If an implementation provides both Big-endian and Little-endian support, then: <ul style="list-style-type: none"> <li>• On a reset to AArch32 state this bit is set to the IMPLEMENTATION DEFINED reset value of: <ul style="list-style-type: none"> <li>— <a href="#">SCTLR.EE</a> if the highest implemented Exception level is not EL2.</li> <li>— <a href="#">HSCTLR.EE</a> if the highest implemented Exception level is EL2.</li> </ul> </li> <li>• On taking an exception to: <ul style="list-style-type: none"> <li>— A PL1 mode using AArch32, this bit is set to <a href="#">SCTLR.EE</a>.</li> <li>— EL2 using AArch32, this bit is set to <a href="#">HSCTLR.EE</a></li> </ul> </li> </ul>
<b>IL</b>	Illegal Execution state bit. See <a href="#">The Illegal Execution state exception on page G1-4363</a> . On a reset or taking an exception to AArch32 state, this bit is set to 0.

For information on how the J, T, IT[7:0], E, and IL fields can be accessed, see [Accessing the PE state controls and the Execution state bit on page G1-4335](#).

### The asynchronous exception mask bits

<b>A</b>	SError interrupt mask bit.
<b>I</b>	IRQ interrupt mask bit.
<b>F</b>	FIQ interrupt mask bit.

For each bit, the values are:

- 0** Exception not masked.
- 1** Exception masked.

On a reset to AArch32 state, these bits are set to 1.

On taking an exception to AArch32 state, one or more of these bits are set to 1.

For more information, see both:

- [Asynchronous exception masking controls on page G1-4368.](#)
- [PE state on exception entry on page G1-4354.](#)

#### The mode bits

**M[4:0]** Current mode of the PE. [Table G1-5 on page G1-4322](#) lists the permitted values of this field. All other values are reserved. [Illegal changes to PSTATE.M on page G1-4336](#) describes the effect of setting M[4:0] to a reserved value.

M[4] is:

##### **M[4], Execution state**

The current Execution state:

- 0** AArch64 state.
- 1** AArch32 state.

##### ———— **Note** ————

This is consistent with the use of M[4:0] in previous versions of the architecture.

On a reset to AArch32 state, M[4:0] is set to:

- 0b10011, meaning Supervisor mode, if the highest implemented Exception level is not EL2.
- 0b11010, meaning Hyp mode, if the highest implemented Exception level is EL2.

On taking an exception to AArch32 state, M[4:0] is set to the target mode for the exception type.

For more information about the PE modes, see:

- [AArch32 PE mode descriptions on page G1-4322.](#)
- [PE state on exception entry on page G1-4354.](#)

#### Access control bits, from ARMv8.1

**PAN** *Privileged Access Never* (PAN) state bit, see [About the PAN bit on page G4-4608.](#)

### G1.10.1 Accessing PSTATE fields

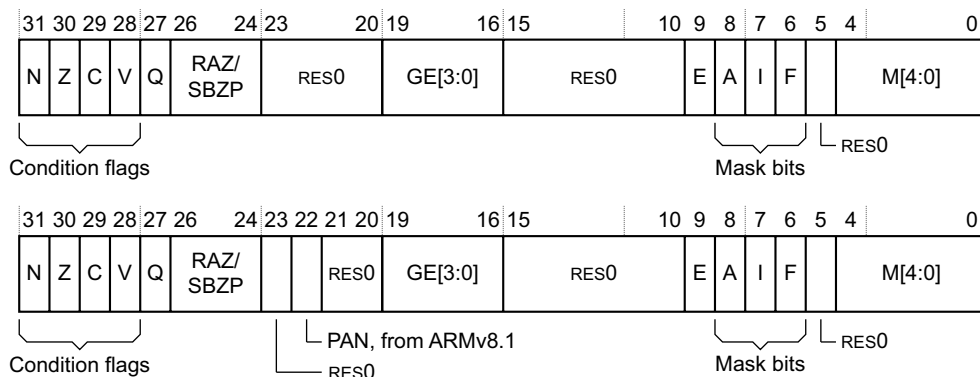

The **PSTATE** fields can be accessed as described in the following subsections:

- [The Current Program Status Register, CPSR on page G1-4334.](#)
- [Accessing the PE state controls and the Execution state bit on page G1-4335.](#)
- [The CPS instruction on page G1-4335.](#)
- [The SETEND instruction on page G1-4336.](#)
- [The SETPAN instruction on page G1-4336.](#)

## The Current Program Status Register, CPSR

Some [PSTATE](#) fields can be accessed using the Special-purpose *Current Program Status Register* (CPSR). The CPSR can be directly read using the [MRS](#) instruction, and directly written using the [MSR \(register\)](#) and [MSR \(immediate\)](#) instructions.

The CPSR bit assignments are:

### N, Z, C, V, bits [31:28]

The [PSTATE](#) Condition flags.

**Q, bit [27]** The [PSTATE](#) overflow or saturation flag.

**Bits[26:24]** Reserved, RAZ/SBZP. Software can use MSR instructions that write the top byte of the CPSR without using a read-modify-write sequence. If it does this, it must write zeros to bits[26:24].

### Bits[23, 21:20, 15:10, 5]

Reserved, RES0.

**Bit[22]** In ARMv8.0, Reserved, RES0.

In ARMv8.1, *Privileged Access Never* (PAN) state bit, see [About the PAN bit on page G4-4608](#).

### GE[3:0], bits [19:16]

The [PSTATE](#) greater than or equal flags.

**E, bit [9]** The [PSTATE](#) endianness bit.

### A, I, F, bits [8:6]

The [PSTATE](#) asynchronous exception mask bits.

### M[4:0], bits [4:0]

The [PSTATE](#) mode bits.

The other [PSTATE](#) fields cannot be accessed by using the CPSR. For information on how to access them, see [Accessing the PE state controls and the Execution state bit on page G1-4335](#).

The application level alias for the CPSR is the [APSR](#). The [APSR](#) is a subset of the CPSR. See [The Application Program Status Register, APSR on page E1-2736](#).

Writes to the CPSR have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the CPSR write. This means that they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

The privilege level and address space of memory accesses associated with fetching instructions depend on the current Exception level and Security state. Writes to [PSTATE.M](#) can change one or both of the Exception level and Security state. The effect, on memory accesses associated with fetching instructions, of a change of Exception level or Security state is:

- Synchronous to the change of Exception level or Security state, if that change is caused by an exception entry or exception return.
- Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
- Guaranteed to be visible to any memory access caused by fetching any instruction after the next [Context synchronization event](#) in the execution stream.
- Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See [Exception return to an Exception level using AArch32](#) on page G1-4360 for the definition of exception return instructions.

### Accessing the PE state controls and the Execution state bit

The PE state controls are the [PSTATE](#).{IL, IT[7:0], J, E, T} fields. Software can read or write these in an [SPSR](#).

In the [CPSR](#):

- The PE state controls, other than [PSTATE.E](#), are RAZ when read by an [MRS](#) instruction.
- Writes to the PE state controls, other than [PSTATE.E](#), by [MSR \(register\)](#) or [MSR \(immediate\)](#), are ignored in all modes.

Instructions other than [MRS](#), [MSR \(register\)](#), or [MSR \(immediate\)](#) that access the PE state controls can read and write them in any mode.

Unlike the other [PSTATE](#) PE state controls, [PSTATE.E](#) can be read by an [MRS](#) instruction and might be written by [MSR \(register\)](#) or [MSR \(immediate\)](#). However, ARM deprecates [PSTATE.E](#) having a different value from the equivalent System register EE bit, see [Mixed-endian support](#) on page G3-4524.

#### ————— Note —————

To determine the current endianness, software can use an LDR instruction to load a word from memory with a known value that differs if the endianness is reversed. For example, using an LDR instruction to load a word whose four bytes are 0x01, 0x00, 0x00, and 0x00 in ascending order of memory address loads the destination register with:

- 0x00000001 if the current endianness is little-endian.
- 0x01000000 if the current endianness is big-endian.

The [PSTATE.M](#)[4] bit is the Execution state bit. When read by an [MRS](#) instruction in AArch32 state, this bit always reads as 1. When written by an [MSR \(register\)](#) instruction or [MSR \(immediate\)](#) instruction, writing a value other than 1 is an illegal change to the [PSTATE.M](#) field. See [Illegal changes to PSTATE.M](#) on page G1-4336.

### The CPS instruction

The A32 and T32 instruction sets both include an instruction to manipulate [PSTATE](#).{A, I, F} and [PSTATE.M](#):

CPSIE <i>iflags</i> {, #<mode>}</p>
</div>
<div data-bbox="311 810 918 839" data-label="Text">
<p>Sets the specified <a href="#>PSTATE</a>.{A, I, F} exception masks to 0, enabling the exception, and optionally changes to the specified mode.</p>
</div>
<div data-bbox="218 849 393 863" data-label="Text">
<p>CPSID <i>iflags</i> {, #<mode>}</p>
</div>
<div data-bbox="311 862 918 891" data-label="Text">
<p>Sets the specified <a href="#>PSTATE</a>.{A, I, F} exception masks to 1, disabling the exception, and optionally changes to the specified mode.</p>
</div>
<div data-bbox="218 899 856 915" data-label="Text">
<p>CPS #<mode> Changes to the specified mode without affecting the <a href="#>PSTATE</a>.{A, I, F} exception masks.</p>
</div>
</div>
<div data-bbox="82 938 199 966" data-label="Page-Footer">
<p>ARM DDI 0487B.a  
ID033117</p>
</div>
<div data-bbox="282 938 712 966" data-label="Page-Footer">
<p>Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.  
Non-Confidential</p>
</div>
<div data-bbox="854 938 922 953" data-label="Page-Footer">
<p>G1-4335</p>
</div>

The CPS instruction is unconditional. For more information, see [CPS](#), [CPSID](#), [CPSIE](#) on page F5-3089.

### The SETEND instruction

The A32 and T32 instruction sets both include an instruction to manipulate [PSTATE.E](#):

SETEND BE      Sets [PSTATE.E](#) to 1, for big-endian operation.  
SETEND LE      Sets [PSTATE.E](#) to 0, for little-endian operation.

The SETEND instruction is unconditional. For more information, see [SETEND](#) on page F5-3411. ARM deprecates use of the SETEND instruction.

### The SETPAN instruction

[ARMv8.1-PAN](#) adds the SETPAN instruction to the A32 and T32 instruction sets, to manipulate [PSTATE.PAN](#):

SETPAN #0      Sets [PSTATE.PAN](#) to 0, disabling Privileged access-never operation.  
SETPAN #1      Sets [PSTATE.PAN](#) to 1, enabling Privileged access-never operation.

The SETPAN instruction is unconditional.

For more information see:

- [SETPAN](#) on page F5-3412.
- [About the PAN bit](#) on page G4-4608.

## G1.10.2 The Saved Program Status Registers (SPSRs)

On taking an exception, [PSTATE](#) is preserved in the SPSR of the mode to which the exception is taken. The SPSRs are described in [Saved Program Status Registers \(SPSRs\)](#) on page G1-4329.

## G1.10.3 Illegal changes to PSTATE.M

In AArch32 PE modes other than User mode, MSR and CPS instructions can explicitly change [PSTATE.M](#). The following changes to [PSTATE.M](#) by MSR or CPS instructions are illegal:

- A change to an encoding that [Table G1-5](#) on page G1-4322 does not show.
- A change to a mode that is not implemented.
- A change to a mode that is not accessible from the context the MRS or CPS instruction is executed in, as follows:
  - A change to a mode that would cause entry to a higher Exception level.
  - When executing in Non-secure state, a change to Monitor mode.
  - When executing in Secure EL1, a change to Monitor mode when EL3 is using AArch64.
  - A change to Hyp mode from any other mode.
  - A change from Hyp mode to any other mode.
  - When the value of [HCR.TGE](#) is 1, attempting to change from Monitor mode to a Non-secure PL1 mode, see [Trapping of general exceptions to Hyp mode](#) on page K1-6116.

On executing an instruction that attempts an illegal change to [PSTATE.M](#):

- [PSTATE.M](#) is unchanged, and the current mode remains unchanged.
- [PSTATE.IL](#) is set to 1.
- All other [PSTATE](#) fields are written to as normal.

#### ————— Note —————

For the [PSTATE](#) fields that MSR and CPS instructions update, see the instruction descriptions:

- [MSR \(register\)](#) on page F5-3287.
- [MSR \(immediate\)](#) on page F5-3285.

- [CPS, CPSID, CPSIE](#) on page F5-3089.
- 

When the value of [PSTATE.IL](#) is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See [The Illegal Execution state exception](#) on page G1-4363.

---

**Note**

- The PE ignores writes to [PSTATE.M](#) when executing at PL0.
  - In ARMv7, an instruction that attempts to make an illegal change to [PSTATE.M](#) is UNPREDICTABLE.
- 

#### G1.10.4 Pseudocode description of PSTATE operations

The [CPSRWriteByInstr\(\)](#) function is used by the [MSR \(register\)](#) and [MSR \(immediate\)](#) instructions to update [PSTATE](#).

The [SetPSTATEFromPSR\(\)](#) function updates [PSTATE](#) from a CPSR or SPSR.

[Chapter J1 ARMv8 Pseudocode](#) defines these functions.

## G1.11 Instruction set states

The instruction set states are described in [Chapter E2 The AArch32 Application Level Memory Model](#) and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- [Exceptions and instruction set state](#).
- [Unimplemented instruction sets](#).

### G1.11.1 Exceptions and instruction set state

If an exception is taken to an EL1 mode, the [SCTLR.TE](#) bit for the Security state the exception is taken to determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the [HSCTLR.TE](#) bit determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

On coming out of reset, if the highest implemented Exception level is using AArch32:

- If the highest implemented Exception level is EL2, the PE starts execution in Hyp mode, in the instruction set state determined by the reset value of [HSCTLR.TE](#).
- Otherwise, the PE starts execution in Supervisor mode, in the instruction set state determined by the reset value of [SCTLR.TE](#). If the implementation includes EL3, this execution is in Secure Supervisor mode.

For more information about exception entry, see [Overview of exception entry on page G1-4347](#).

### G1.11.2 Unimplemented instruction sets

The [PSTATE.T](#) bit defines the current instruction set state, see [Process state, PSTATE on page E1-2734](#).

In the ARMv8 architecture there is no support for the hardware acceleration of Java bytecodes, and the Jazelle Instruction set state is obsolete. Every AArch32 implementation must support the Trivial Jazelle implementation described in [Trivial implementation of the Jazelle extension](#).

#### ———— Note ————

In previous versions of the ARM architecture, the [PSTATE.{J, T}](#) bits determined the Instruction set state. In ARMv8, [PSTATE.J](#) is RES0.

### Trivial implementation of the Jazelle extension

ARMv8 requires that the implementation of AArch32 state includes the trivial Jazelle implementation.

In a trivial implementation of the Jazelle extension:

- At EL1, EL2, or EL3, if the Exception level is using AArch32:
  - The [JMCR](#) and [JOSCR](#) are RAZ/WI.
  - The [JIDR](#) is a RAZ read-only register.
- At EL0 when EL0 is using AArch32:
  - It is IMPLEMENTATION DEFINED whether the [JMCR](#) and [JOSCR](#) are RAZ/WI or UNDEFINED.
  - It is IMPLEMENTATION DEFINED whether [JIDR](#) is RAZ or UNDEFINED.
- The [BXJ](#) instruction behaves identically to the [BX](#) instruction in all circumstances.

#### ———— Note ————

This is consistent with the [JMCR.JE](#) bit being RAZ, and means that the A32 and T32 instruction sets do not provide any mechanism for attempting to enter Jazelle state.

- Jazelle state, as defined in previous versions of the ARM architecture, is an unimplemented instruction set state.

These requirements ensure that operating systems that support an EJVM execute correctly.

A trivial implementation is not required to extend the PC to 32 bits, that is, it can implement PC[0] as RAZ/WI.

———— **Note** —————

This is because the only way that PC[0] is visible in A32 or T32 state is as a result of an exception occurring during Jazelle state execution, and Jazelle state execution cannot occur on a trivial implementation.

—————

## G1.12 Handling exceptions that are taken to an Exception level using AArch32

An exception causes the PE to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the PE state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the PE is handling an exception.

The following sections describe exception handling:

- [Exception vectors and the exception base address.](#)
- [Exception prioritization for exceptions taken to AArch32 state on page G1-4344.](#)
- [Overview of exception entry on page G1-4347.](#)
- [PE mode for taking exceptions on page G1-4350.](#)
- [PE state on exception entry on page G1-4354.](#)
- [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356.](#)
- [Routing debug exceptions to EL2 using AArch32 on page G1-4358.](#)
- [Exception return to an Exception level using AArch32 on page G1-4360.](#)

[Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365](#) gives a full description of asynchronous exception handling, for exceptions taken asynchronously from AArch32 state.

### ———— Note ————

Because of the common model for handling exceptions, the current section requires some understanding of the asynchronous exception behaviors described in [Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365](#).

[AArch32 state exception descriptions on page G1-4376](#) then describes each exception.

### G1.12.1 Exception vectors and the exception base address

When an exception is taken, PE execution is forced to an address that corresponds to the type of exception. This address is called the *exception vector* for that exception. The vectors for the different types of exception form a *vector table*.

### ———— Note ————

There are significant differences in the sets of exception vectors for exceptions taken to an Exception level that is using AArch32 and for exceptions taken to an Exception level that is using AArch64. This part of this manual describes only how exceptions are taken to an Exception level that is using AArch32. So, for example, when executing at EL1 or EL0, an exception might be generated that must be taken to EL3. In this case:

- If EL3 is using AArch32 then the exception is taken as described in this chapter, using the exception vectors described in this section.
- If EL3 is using AArch64 then the exception is taken as described in [Chapter D1 The AArch64 System Level Programmers' Model](#) using the exception vectors described in [Exception vectors on page D1-1800](#).

AArch32 state defines exception vector tables for exceptions taken to EL2 and EL3 when those Exception levels are using AArch32. Those vector tables are not used when the corresponding Exception levels are using AArch64.

A set of exception vectors for an Exception level that is using AArch32 comprises eight consecutive word-aligned memory addresses, starting at an *exception base address*. These eight vectors form an AArch32 *vector table*.

The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented Exception levels, as follows:

#### Implementation that does not include EL3

Any implementation that does not include EL3 must include the following AArch32 vector table if EL1 can use AArch32:

- An exception table for exceptions taken to EL1 modes other than System mode. This is the EL1 vector table, and is in the address space of the PL1&0 translation regime.

#### ———— Note ————

Exceptions cannot be taken to System mode.

For this vector table, the [VBAR](#) holds the exception base address.

#### Implementation that includes EL2

Any implementation that includes EL2 must include the following additional AArch32 vector table if EL2 can use AArch32:

- An exception table for exceptions taken to Hyp mode. This is the Hyp vector table, and is in the address space of the Non-secure PL2 translation regime.

For this vector table, [HVBAR](#) holds the exception base address.

#### Implementation that includes EL3

Any implementation that includes EL3 must include the following AArch32 vector tables:

- If EL3 can use AArch32, a vector table for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, [MVBAR](#) holds the exception base address.

- If Secure EL1 can use AArch32, a vector table for exceptions taken to Secure privileged modes other than Monitor mode and System mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, the Secure [VBAR](#) holds the exception base address.

- If Non-secure EL1 can use AArch32, a vector table for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.

For this vector table, the Non-secure [VBAR](#) holds the exception base address.

The following subsections give more information:

- [The vector tables and exception offsets.](#)
- [Pseudocode determination of the exception base address on page G1-4344.](#)

#### The vector tables and exception offsets

[Table G1-6 on page G1-4342](#) defines the AArch32 vector table entries. In this table:

- The *Hyp mode* column defines the vector table entries for exceptions taken to Hyp mode.
- The *Monitor mode* column defines the vector table entries for exceptions taken to Monitor mode.
- The *Secure* and *Non-secure* columns define the Secure and Non-secure vector table entries, that are used for exceptions taken to modes other than Monitor mode, Hyp mode, System mode, and User mode. [Table G1-7 on page G1-4342](#) shows the mode to which each of these exceptions is taken. Each of these modes is described as the *default* mode for taking the corresponding exception.

#### ———— Note ————

Exceptions cannot be taken to System mode or User mode.

For more information about determining the mode to which an exception is taken, see [PE mode for taking exceptions on page G1-4350](#).

When EL2 is using AArch32, it provides a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see [interrupt Offsets of AArch32 exceptions provided by EL2 on page G1-4343](#).

**Table G1-6 The AArch32 vector tables**

Offset	Vector tables			
	Hyp <sup>a</sup>	Monitor <sup>b</sup>	Secure <sup>c</sup>	Non-secure <sup>c</sup>
0x00	Not used	Not used	Not used <sup>d</sup>	Not used
0x04	Undefined Instruction, from Hyp mode	Monitor Trap	Undefined Instruction	Undefined Instruction
0x08	Hypervisor Call, from Hyp mode	Secure Monitor Call	Supervisor Call	Supervisor Call
0x0C	Prefetch Abort, from Hyp mode	Prefetch Abort	Prefetch Abort	Prefetch Abort
0x10	Data Abort, from Hyp mode	Data Abort	Data Abort	Data Abort
0x14	Hyp Trap, or Hyp mode entry <sup>e</sup>	Not used	Not used	Not used
0x18	IRQ interrupt	IRQ interrupt	IRQ interrupt	IRQ interrupt
0x1C	FIQ interrupt	FIQ interrupt	FIQ interrupt	FIQ interrupt

- a. Non-secure state only. Implemented only if the implementation includes EL2 and EL2 can use AArch32.
- b. Secure state only. Implemented only if the implementation includes EL3 and EL3 can use AArch32.
- c. If the implementation does not include EL3 then there is a single vector table for exceptions taken to EL1 when EL1 is using AArch32. That table holds the vectors shown in the Secure column of this table
- d. In previous versions of the architecture, this entry has been used for the Reset vector, meaning the address at which execution starts on coming out of reset. In ARMv8, the AArch32 Reset vector is IMPLEMENTATION DEFINED. An implementation might use this vector table entry to hold the Reset vector.
- e. See [Use of offset 0x14 in the Hyp vector table on page G1-4343](#).

**Table G1-7 Modes for taking the exceptions shown in the Secure or Non-secure vector table**

Exception	Mode taken to
Undefined Instruction	Undefined
Supervisor Call	Supervisor
Prefetch Abort	Abort
Data Abort	Abort
IRQ interrupt	IRQ
FIQ interrupt	FIQ

For more information about use of the vector tables see [Overview of exception entry on page G1-4347](#).

### **interrupt Offsets of AArch32 exceptions provided by EL2**

EL2 provides the following exceptions. When EL2 is using AArch32, these exceptions are taken to Hyp mode, and the PE enters the handlers for these exceptions using the following vector table entries shown in [Table G1-6 on page G1-4342](#):

#### **Hypervisor Call**

If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see [Use of offset 0x14 in the Hyp vector table](#).

**Hyp Trap** Shown explicitly in the Hyp mode vector table.

**Virtual Abort** Entered through the Data Abort vector in the Non-secure vector table.

**Virtual IRQ** Entered through the IRQ vector in the Non-secure vector table.

**Virtual FIQ** Entered through the FIQ vector in the Non-secure vector table.

#### **———— Note ————**

[Virtual exceptions when an implementation includes EL2 on page G1-4365](#) gives more information about the virtual exceptions.

### **Use of offset 0x14 in the Hyp vector table**

The vector at offset 0x14 in the Hyp vector table is used for exceptions that cause entry to Hyp mode. This means it is:

- Always used for the Hyp Trap exception.
- Used for any Hypervisor Call exception that is taken from a mode other than Hyp mode.
- Used for any Supervisor Call exception that is taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
- Used for any Undefined Instruction that is taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
- Used for any Prefetch Abort exception that is:
  - Taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
  - Generated by a Debug exception from Non-secure state when the value of [HDCR.TDE](#) is 1.
  - Generated by a stage 2 abort on an address translation instruction.
- Used for any Data Abort exception that is:
  - Taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
  - Generated by an SError interrupt from Non-secure state when the value of [HCR.AMO](#) is 1.
  - Generated by a Watchpoint exception from Non-secure state when the value of [HDCR.TDE](#) is 1.
  - Generated by a stage 2 abort on an address translation operation.

#### **———— Note ————**

Offset 0x14 is never used for the following exceptions:

- IRQ exceptions.
- Virtual IRQ exceptions.
- FIQ exceptions.
- Virtual FIQ exceptions.

Virtual exceptions are never taken to Hyp mode.

For more information, see [PE mode for taking exceptions on page G1-4350](#).

### **Pseudocode determination of the exception base address**

For an exception taken to a PL1 mode, the `ExcVectorBase()` function determines the exception base address.

The `ExcVectorBase()` function is defined in [Chapter J1 ARMv8 Pseudocode](#).

---

#### **Note**

The PL1 modes to which exceptions can be taken are Supervisor mode, Undefined mode, Abort mode, IRQ mode, and FIQ mode. In Non-secure state, and in Secure state when EL3 is using AArch64, these are EL1 modes. However, in Secure state when EL3 is using AArch32, these are EL3 modes. For more information see [Security state, Exception levels, and AArch32 execution privilege on page G1-4318](#).

---

## **G1.12.2 Exception prioritization for exceptions taken to AArch32 state**

The following sections describe the ARMv8 requirements for the prioritization of synchronous exceptions, and the limits on when asynchronous exceptions can be taken:

- [Synchronous exception prioritization for exceptions taken to AArch32 state](#).
- [Architectural requirements for taking asynchronous exceptions on page G1-4346](#).

See also:

- [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660](#), for information about:
  - The prioritization of aborts on a single memory access in a VMSA implementation.
  - The prioritization of exceptions generated during address translation.
- [Debug state entry and debug event prioritization on page H2-5437](#) for information about the relative prioritization of exceptions and the debug events that cause entry to Debug state.

### **Synchronous exception prioritization for exceptions taken to AArch32 state**

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. This section describes the prioritization of such exceptions when they are taken to an Exception level that is using AArch32.

---

#### **Note**

- An exception that is taken to an Exception level that is using AArch32 must have been taken from an Exception level that is using AArch32.
  - The priority numbering in this list only shows the relative priorities of exceptions taken to an Exception level that is using AArch32. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#).
- 

For an exception that is taken to an Exception level that is using AArch32, exceptions are prioritized as follows, where 1 is the highest priority.

1. PC alignment fault exceptions. A PC alignment fault exception can only be taken to an Exception level that is using AArch32 as a result of:
  - The CONSTRAINED UNPREDICTABLE handling of a branch to an unaligned address, see [Branching to an unaligned PC on page K1-6098](#).
  - Exiting from Debug state to AArch32 specifying an unaligned PC value, see [Exiting Debug state on page H2-5471](#).

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, see [Prefetch Abort exception reporting a PC alignment fault exception on page G1-4385](#).

2. Prefetch Abort exceptions. See [Prefetch Abort exception on page G1-4384](#) and [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4660](#).
3. Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
  - [Breakpoint exceptions on page G2-4470](#).
  - [Vector Catch exceptions on page G2-4510](#).

**Note**

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in this section. This means that it does not have its own entry in this list.

4. Illegal Execution state exceptions. See [The Illegal Execution state exception on page G1-4363](#).
5. Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
  - [HSTR.Tn](#).
  - [HCR.TIDCP](#).
6. Undefined Instruction exceptions that occur as a result of one or more of the following:
  - An attempt to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
  - An attempt to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
  - Debug state execution of an instruction encoding that is unallocated in Debug state.
  - Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
  - Execution of an HVC instruction, when HVC instructions are disabled by [SCR.HCE](#) or [HCR.HCD](#).
  - Execution of an HLT instruction when HLT instructions are disabled by [EDSCR.HDE](#).
  - In Debug state:
    - Execution of a DCP51 instruction in Non-secure EL0 when [HCR.TGE](#) is 1.
    - Execution of a DCP52 instruction in EL1 or EL0 when [SCR.NS](#) is 0 or when EL2 is not implemented.
    - Execution of a DCP53 instruction when [EDSCR.SDD](#) is 1 or when EL3 is not implemented.
    - When the value of [EDSCR.SDD](#) is 1, execution in EL2, EL1, or EL0 of an instruction that is trapped to EL3.
  - Execution of an instruction that is UNDEFINED as a result of any of:
    - Being in an IT block when [SCTLR.ITD](#) is 1, or when [HSCTLR.ITD](#) is 1.
    - Executing a SETEND instruction when [SCTLR.SED](#) is 1, or when [HSCTLR.SED](#) is 1.
    - Executing a [CP15DMB](#), [CP15DSB](#), or [CP15ISB](#) barrier instruction when [SCTLR.CP15BEN](#) is 0, or when [HSCTLR.CP15BEN](#) is 0.

See [Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality on page G1-4421](#) and [Disabling or enabling EL2 use of AArch32 deprecated functionality on page G1-4430](#).

  - Execution of an instruction that is UNDEFINED because at least one of [FPSCR](#).{Stride, Len} is nonzero, when programming these bits to nonzero values is supported. See [Floating-point exception traps on page G1-4416](#).
7. Exceptions taken to EL1, or taken to EL2 because the value of [HCR.TGE](#) is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 1-6.
8. Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
  - [HSTR.Tn](#).
  - [HCR.TIDCP](#).
9. Exceptions taken to EL2 because of configuration settings in the [HCPTR](#).

10. Exceptions taken to EL2 because of one of the following configuration settings:
  - Any setting in [HCR](#), other than the TIDCP bit.
  - Any setting in [CNTHCTL](#).
  - Any setting in [HDCR](#).
11. Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities [1](#) - [10](#).
12. Exceptions caused by the SMC instruction being UNDEFINED because the value of [SCR.SCD](#) is 1.
13. Exceptions caused by the execution of an Exception generating instruction, SVC, HVC, SMC, or BKPT.
14. Exceptions taken to EL3 because of configuration settings in the [SDCR](#). These might be taken from EL0, EL1, or EL2.
15. Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities [1](#) - [14](#).
16. Trapped floating-point exceptions, if supported. See [Floating-point exception traps](#) on page G1-4416.
17. Data Abort exceptions other than a Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk. That is, any Data Abort exception that is not covered by item [19](#). See [Data Abort exception](#) on page G1-4387 and [AArch32 state prioritization of synchronous aborts from a single stage of address translation](#) on page G4-4660. It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item [19](#).
18. Watchpoint exceptions. See [Watchpoint exceptions](#) on page G2-4496.
19. Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk, see [External aborts](#) on page G3-4550. It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item [17](#).

For items [17](#) - [19](#), if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

———— **Note** ————

Exceptions generated by a translation table walk are reported and prioritized as either a Prefetch Abort exception, priority [2](#) in this list, or a Data Abort exception, priority [17](#) in this list. See also [AArch32 state prioritization of synchronous aborts from a single stage of address translation](#) on page G4-4660.

## Architectural requirements for taking asynchronous exceptions

The ARM architecture does not define when asynchronous exceptions are taken. The prioritization of asynchronous exceptions, including virtual asynchronous exceptions, is IMPLEMENTATION DEFINED.

An asynchronous exception that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event completes its execution, provided that the pending asynchronous event is not masked:

- Execution of an ISB instruction that does not fail its Condition code check.
- Exception entry.
- Exception return.
- Exit from Debug state.

---

**Note**

- If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.
- The [ISR](#) identifies any pending asynchronous exceptions.
- Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.

---

In the absence of a specific requirement to take an asynchronous exception, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

---

**Note**

The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.

---

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken then it must be taken before the first [Context synchronization event](#) after the interrupt was changed to not pending.

[PSTATE](#) includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the corresponding asynchronous exception from being taken, although when the PE is in Non-secure state other controls can modify the effect of these bits. For more information, see [Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365](#).

Taking an exception sets an exception-dependent subset of these mask bits.

---

**Note**

In some contexts, the [PSTATE](#).{A, I, F} bits mask the taking of asynchronous exceptions. The way these are set on exception entry, described in [PSTATE.{A, I, F, M} values on exception entry on page G1-4355](#), can prevent an exception handler being interrupted by an asynchronous exception.

### G1.12.3 Overview of exception entry

There are some significant differences between the handling of exceptions taken to Hyp mode and exceptions taken to other modes. Because Hyp mode is the EL2 mode, this means that the following descriptions sometimes distinguish between the *EL2 mode* and the *non-EL2 modes*.

On taking an exception to an Exception level that is using AArch32:

1. The hardware determines the mode to which the exception must be taken, see [PE mode for taking exceptions on page G1-4350](#).
2. A link value, indicating the *preferred return address* for the exception, is saved. This is a possible return address for the exception handler, and depends on:
  - The exception type.
  - Whether the exception is taken to the EL2 mode or to a non-EL2 mode.
  - For some exceptions taken to non-EL2 modes, the instruction set state when the exception was taken.

Where the link value is saved depends on whether the exception is taken to the EL2 mode.

For more information see [Link values saved on exception entry on page G1-4349](#).

3. The value of [PSTATE](#) is saved in the [SPSR](#) for the mode to which the exception must be taken. The value saved in [SPSR.IT\[7:0\]](#) is always correct for the preferred return address.

4. In an implementation that includes EL3, when EL3 is using AArch32:
  - If the exception is taken from Monitor mode, **SCR.NS** is cleared to 0.
  - Otherwise, taking the exception leaves **SCR.NS** unchanged.
When EL3 is using AArch64, Monitor mode is not available.
5. **PSTATE** is updated with new context information for the exception handler. This includes:
  - Setting **PSTATE.M** to the PE mode to which the exception is taken.
  - Setting the appropriate **PSTATE** mask bits. This can disable the corresponding exceptions, preventing uncontrolled nesting of exception handlers.
  - Setting the instruction set state to the state required for exception entry.
  - Setting the endianness to the required value for exception entry.
  - Clearing the **PSTATE.IT[7:0]** bits to 0.
For more information, see *PE state on exception entry* on page G1-4354.
6. The appropriate exception vector is loaded into the PC, see *Exception vectors and the exception base address* on page G1-4340.
7. Execution continues from the address held in the PC.

For an exception taken to a non-EL2 mode, on exception entry, the exception handler can use the SRS instruction to store the return state onto the stack of any mode at the same Exception level and in the same Security state, and can use the CPS instruction to change mode. For more information about the instructions, see *SRS, SRSDA, SRSDb, SRSIA, SRSIB* on page F5-3464 and *CPS, CPSID, CPSIE* on page F5-3089.

Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the PE state changes on taking that exception. Table G1-8 gives an index to these descriptions:

**Table G1-8 Pseudocode descriptions of exception entry for exceptions taken to AArch32 state**

Exception	Description of exception entry
Reset	<i>Pseudocode descriptions of reset</i> on page G1-4402
Undefined Instruction	<i>Pseudocode description of taking the Undefined Instruction exception</i> on page G1-4378
Hyp Trap	<i>Pseudocode description of taking the Hyp Trap exception</i> on page G1-4380
Monitor Trap	<i>Pseudocode description of taking the Monitor Trap exception</i> on page G1-4379
Supervisor Call	<i>Pseudocode description of taking the Supervisor Call exception</i> on page G1-4381
Secure Monitor Call	<i>Pseudocode description of taking the Secure Monitor Call exception</i> on page G1-4382
Hypervisor Call	<i>Pseudocode description of taking the Hypervisor Call exception</i> on page G1-4383
Prefetch Abort	<i>Pseudocode description of taking the Prefetch Abort exception</i> on page G1-4387
Data Abort	<i>Pseudocode description of taking the Data Abort exception</i> on page G1-4390
Virtual Abort	<i>Pseudocode description of taking the Virtual SError interrupt exception</i> on page G1-4392
IRQ	<i>Pseudocode description of taking the physical IRQ exception</i> on page G1-4394
Virtual IRQ	<i>Pseudocode description of taking the Virtual IRQ exception</i> on page G1-4395
FIQ	<i>Pseudocode description of taking the FIQ exception</i> on page G1-4396
Virtual FIQ	<i>Pseudocode description of taking the Virtual FIQ exception</i> on page G1-4397

The following sections give more information about the PE state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- [PE mode for taking exceptions on page G1-4350.](#)
- [PE state on exception entry on page G1-4354.](#)

### Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the *preferred return address for the exception*, as shown in [Table G1-9](#):

**Table G1-9 Exception return addresses for exceptions taken to AArch32 state**

Exception	Preferred return address	Taken to a mode at
Undefined Instruction	Address of the UNDEFINED instruction	Non-EL2 <sup>a</sup> , or EL2 <sup>c</sup>
Hyp Trap	Address of the trapped instruction	EL2 only <sup>c</sup>
Monitor Trap	Address of the trapped instruction	EL3 only
Supervisor Call	Address of the instruction after the SVC instruction	Non-EL2 <sup>a</sup> or EL2 <sup>c</sup>
Secure Monitor Call	Address of the instruction after the SMC instruction	EL3 <sup>b</sup> , and only in Secure state
Hypervisor Call	Address of the instruction after the HVC instruction	EL2 only <sup>c</sup>
Prefetch Abort	Address of aborted instruction fetch	Non-EL2 <sup>a</sup> or EL2 <sup>c</sup>
Data Abort	Address of instruction that generated the abort	Non-EL2 <sup>a</sup> or EL2 <sup>c</sup>
Virtual Abort	Address of next instruction to execute	EL1, and only in Non-secure state
IRQ or FIQ	Address of next instruction to execute	Non-EL2 <sup>a</sup> or EL2 <sup>c</sup>
Virtual IRQ or Virtual FIQ	Address of next instruction to execute	EL1, and only in Non-secure state

- EL1 if the exception is taken to a Non-secure mode, or is taken to a Secure mode when EL3 is using AArch64. EL3 if the exception is taken to a Secure mode when EL3 is using AArch64.
- A Secure Monitor Call exception is taken to EL3, and therefore is taken to AArch32 state only if EL3 is using AArch32, in which case it is taken to Monitor mode.
- EL2 is implemented only in Non-secure state. Therefore, an exception can be taken to EL2 mode only if it is taken from Non-secure state.

### Note

- Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.
- For each exception, the preferred return address is not affected by the Exception level from which the exception was taken.

The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to an EL2 mode, as follows:

#### Exception taken to a non-EL2 mode

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as [Table G1-10](#) shows:

**Table G1-10 Offsets applied to Link value for exceptions taken to non-EL2 modes**

Exception	Offset, for PE state of:	
	A32	T32
Undefined Instruction	+4	+2
Monitor Trap	+4	+2
Supervisor Call	None	None
Secure Monitor Call	None	None
Prefetch Abort	+4	+4
Data Abort	+8	+8
Virtual Abort	+8	+8
IRQ or FIQ	+4	+4
Virtual IRQ or Virtual FIQ	+4	+4

#### Exception taken to an EL2 mode

The link value is saved in the [ELR\\_hyp](#) Special-purpose register.

The saved link value is the preferred return address for the exception, as shown in [Table G1-9 on page G1-4349](#), with no offset.

### G1.12.4 PE mode for taking exceptions

The following principles determine the Exception level to which an exception is taken, and if that Exception level is using AArch32, the PE mode to which the exception is taken:

- An exception cannot be taken to the EL0 mode.
- An exception is taken either:
  - To the Exception level at which the PE was executing when it took the exception.
  - To a higher Exception level.

This means that, in Secure state:

  - When EL3 is using AArch32, an exception is always taken to an EL3 mode.
  - When EL3 is using AArch64, an exception that is taken to AArch32 state is taken to an EL1 mode.
- Configuration options and other features provided by EL2 and EL3 can determine the mode to which some exceptions are taken, as follows:

#### In an implementation that does not include EL2 or EL3

An exception is always taken to the default mode for that exception.

### In an implementation that includes EL3

A Secure Monitor Call exception is always taken to EL3. This means:

- If EL3 is using AArch32 the exception is taken to Secure Monitor mode.
- If EL3 is using AArch64 then executing the instruction generates an exception that is taken to EL3, see *Execution of an SMC instruction from a privileged Exception level that is using AArch32* on page G1-4352.

IRQ, FIQ, and External abort exceptions can be configured to be taken to EL3. Therefore, if EL3 is using AArch32 the exceptions are taken to Secure Monitor mode.

When EL3 is using AArch32, a Monitor Trap exception is taken to Secure Monitor mode.

Any exception taken from Secure state that is not taken to Secure Monitor mode is taken to Secure state in the default mode for that exception. As described in *Security state, Exception levels, and AArch32 execution privilege* on page G1-4318, this means it is taken to:

- An EL3 mode other than Monitor mode if EL3 is using AArch32.
- An EL1 mode if EL3 is using AArch64.

If the implementation does not include EL2, any exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state to the default mode for that exception. The default mode will be an EL1 mode.

### In an implementation that includes EL2

An exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state and:

- If the exception is taken from Hyp mode then it is taken to Hyp mode.
- Otherwise, the exception is either taken to Hyp mode, as described in *Exceptions taken to Hyp mode* on page G1-4352, or taken to the default mode for the exception.

#### ————— Note —————

- Hyp mode is the EL2 mode. The other modes to which an exception can be taken in Non-secure state are EL1 modes.
- EL2 has no effect on the handling of exceptions taken from Secure state.

Table G1-7 on page G1-4342 shows the default mode to which each exception is taken.

*Asynchronous exception routing controls* on page G1-4367 describes the exception routing controls provided by EL2 and EL3.

*Routing of aborts taken to AArch32 state* on page G4-4649 gives more information about the modes to which memory aborts are taken.

*The possible modes for taking each exception* on page G1-4353 shows all modes to which each exception might be taken, in any implementation. That is, it applies to implementations:

- That include neither EL2 nor EL3.
- That include EL2 but not EL3
- That do not include EL2 but include EL3
- That include both EL2 and EL3.

## Exceptions taken to Hyp mode

In an implementation that includes EL2 and EL3, when EL2 is using AArch32:

- Any exception taken from Hyp mode, that is not routed to EL3 by the controls described in [Asynchronous exception routing controls on page G1-4367](#), is taken to Hyp mode.
  - The following exceptions, if taken from Non-secure state, are taken to Hyp mode:
    - An abort that [Routing of aborts taken to AArch32 state on page G4-4649](#) identifies as taken to Hyp mode.
    - A Hyp Trap exception, see [EL2 configurable controls on page G1-4427](#).
    - A Hypervisor Call exception. This is generated by executing an HVC instruction in a Non-secure mode.
    - An SError interrupt exception, IRQ exception or FIQ exception that is not routed to EL3 but is explicitly routed to Hyp mode, as described in [Asynchronous exception routing controls on page G1-4367](#).
    - A synchronous external abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the Non-secure EL0 mode and explicitly routed to Hyp mode, as described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356](#).
- **Note** ————
- A synchronous external abort can be routed to Hyp mode only if it is not routed to EL3.
- **Note** ————
- A debug exception that is explicitly routed to Hyp mode as described in [Routing debug exceptions to EL2 using AArch32 on page G1-4358](#).

———— **Note** ————

The virtual exceptions cannot be taken to Hyp mode. They are always taken to a Non-secure EL1 mode.

## Security behavior in Exception levels using AArch32 when EL3 is using AArch64

As described in [The ARMv8-A security model on page G1-4315](#), when EL3 is using AArch64, lower Exception levels, in either Security state, can be using AArch32. This means software executing in those Exception levels might try to access AArch32 security features that are not available. The following subsections describe the associated behaviors:

- [Execution of an SMC instruction from a privileged Exception level that is using AArch32](#)
- [Non-secure reads of the NSACR](#)
- [Secure EL1 operations when Secure EL1 is using AArch32 on page G1-4353](#)

### Execution of an SMC instruction from a privileged Exception level that is using AArch32

When EL3 is using AArch64, an SMC instruction executed from Secure or Non-secure EL1 using AArch32, or from Non-secure EL2 using AArch32 when the value of HCR.TSC is 0, generates an exception that is taken to EL3. The exception syndrome is reported with an EC value of 0x13, SMC instruction executed in AArch32 state, see [Exception from SMC instruction execution in AArch32 state on page D1-1809](#).

### Non-secure reads of the NSACR

The NSACR is defined as being RO from Non-secure PE modes other than User mode. When EL3 is using AArch64, a read of the NSACR returns a fixed value of 0x00000C00 in the following cases:

- If the read is from a Non-secure EL1 mode when EL1 is using AArch32.
- If the read is from Hyp mode when EL2 is using AArch32.

### Secure EL1 operations when Secure EL1 is using AArch32

When Secure EL1 is using AArch32 and EL3 is using AArch64:

- Any of the following operations performed in a Secure EL1 mode is trapped to Secure EL3:
  - A read or write of any of the [SCR](#), [NSACR](#), [MVBAR](#), and [SDCR](#).
  - Executing any of the [ATS12NSO\\*\\*](#) instructions.
  - Executing an SRS instruction that would use SP\_mon, see [SRS](#), [SRSDA](#), [SRSDDB](#), [SRSIA](#), [SRSIB](#) on [page F5-3464](#).
  - Executing an MRS (Banked register) or MSR (Banked register) instruction that would access SPSR\_mon, SP\_mon, or LR\_mon, see [MRS \(Banked register\)](#) on [page F5-3277](#) and [MSR \(Banked register\)](#) on [page F5-3281](#).

For more information about these traps, including the associated exception syndromes, see [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32](#) on [page D1-1870](#).

- Writes to the [CNTFRQ](#) register are UNDEFINED.
- Any attempt to move into Monitor mode, either by an exception return or by executing a CPS or MSR instruction, is treated as an illegal operation and is handled as described in [Illegal return events from AArch32 state](#) on [page G1-4361](#).

#### ————— **Note** —————

This functionality supports a usage model where:

- EL3 uses AArch64.
- Secure software executed in Secure EL1 using AArch32 and Secure EL0 using AArch32.
- The Non-secure state uses AArch64.

### The possible modes for taking each exception

Each of the exception descriptions in [AArch32 state exception descriptions](#) on [page G1-4376](#) includes a subsection that describes the modes to which each exception can be taken. Those subsections are:

- [The PE mode to which the Undefined Instruction exception is taken](#) on [page G1-4377](#).
- [The PE mode to which the Hyp Trap exception is taken](#) on [page G1-4380](#).
- [The PE mode to which the Monitor Trap exception is taken](#) on [page G1-4379](#).
- [The PE mode to which the Supervisor Call exception is taken](#) on [page G1-4381](#).
- [The PE mode to which the Secure Monitor Call exception is taken](#) on [page G1-4382](#).
- [The PE mode to which the Hypervisor Call exception is taken](#) on [page G1-4383](#).
- [The PE mode to which the Prefetch Abort exception is taken](#) on [page G1-4386](#).
- [The PE mode to which the Data Abort exception is taken](#) on [page G1-4389](#).
- [The PE mode to which the Virtual SError interrupt exception is taken](#) on [page G1-4392](#).
- [The PE mode to which the physical IRQ exception is taken](#) on [page G1-4393](#).
- [The PE mode to which the Virtual IRQ exception is taken](#) on [page G1-4394](#).
- [The PE mode to which the physical FIQ exception is taken](#) on [page G1-4396](#).
- [The PE mode to which the Virtual FIQ exception is taken](#) on [page G1-4397](#).

These descriptions also show the vector offset for the exception entry for each mode. These descriptions assume that all Exception levels are using AArch32, meaning:

- [HCR](#), rather than [HCR\\_EL2](#), controls the routing of exceptions to EL2.
- [SCR](#), rather than [SCR\\_EL3](#), controls the routing of exceptions to EL3.

For more information about:

- Vector offsets, see [Exception vectors and the exception base address](#) on page G1-4340.
- The routing of synchronous external aborts or SError, IRQ, and FIQ interrupt exceptions, and the virtual exceptions, see [Asynchronous exception routing controls](#) on page G1-4367.

#### UNPREDICTABLE cases when the value of HCR.TGE is 1

When the value of HCR.TGE is 1, exceptions that would otherwise be taken to EL1 are, instead, routed to EL2, see [Routing exceptions from Non-secure EL0 to EL2](#) on page G1-4356. Related to this, when the value of HCR.TGE is 1, execution in a Non-secure EL1 mode is UNPREDICTABLE. ARMv8 does not constrain this UNPREDICTABLE behavior, but in ARMv8 software that follows the ARM recommendations cannot get to this state. When following the ARM recommendations, any attempt to move to a Non-secure EL1 mode when the value of HCR.TGE is 1 is either:

- An illegal exception return, see [Illegal return events from AArch32 state](#) on page G1-4361.
- An illegal PE mode change, see [Illegal changes to PSTATE.M](#) on page G1-4336.

### G1.12.5 PE state on exception entry

The description of each exception includes a pseudocode description of entry to that exception, as [Table G1-8](#) on page G1-4348 shows. The following sections describe the PE state changes on entering an exception, for different implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:

- [Instruction set state on exception entry.](#)
- [PSTATE.E value on exception entry](#) on page G1-4355.
- [PSTATE.{A, I, F, M} values on exception entry](#) on page G1-4355.

#### ———— Note ————

The descriptions in these sections assume that EL2 and EL3, that control some aspects of the routing of exceptions taken from EL1 or EL0, are both using AArch32. If this is not the case:

- If EL2 is using AArch64:
  - Controls shown as provided by the HSCTLR are provided by the SCTLR\_EL2.
  - Controls shown as provided by the HCR are provided by the HCR\_EL2.
- If EL3 is using AArch64, controls shown as provided by the SCR are provided by the SCR\_EL3.

#### Instruction set state on exception entry

Exception handlers can execute in either T32 state or A32 state. On exception entry, PSTATE.T is set to the required value, as determined by SCTLR.TE or HSCTLR.TE, depending on the mode the exception is taken to. [Table G1-11](#) shows this:

**Table G1-11 PSTATE.T bit value on exception entry**

Mode to which exception is taken	HSCTLR.TE	SCTLR.TE	PSTATE.T	Exception handler state
Not Hyp mode	x	0	0	A32
		1	1	T32
Hyp mode	0	x	0	A32
	1	x	1	T32

When an implementation includes EL3 and EL3 is using AArch32, **SCTLR** is Banked for Secure and Non-secure states, and therefore the TE bit value might be different for Secure and Non-secure states. For an exception taken to a PE mode other than Hyp mode, the **SCTLR**.TE bit for the Security state to which the exception is taken determines the instruction set state for the exception handler. This means the instruction set state in which an exception handler might depending on the Security state to which the exception is taken.

### PSTATE.E value on exception entry

**PSTATE**.E controls the load and store endianness for data handling. Table G1-12 show the value to which this bit is set on exception entry:

Table G1-12 **PSTATE**.E value on exception entry

Exception mode	HSCTLR.EE	SCTLR.EE	Endianness for data loads and stores	PSTATE.E
Secure or Non-secure EL1	x	0	Little-endian	0
		1	Big-endian	1
Hyp	0	x	Little-endian	0
	1	x	Big-endian	1

For more information, see the bit description in *SPSR format for exceptions taken to AArch32 state on page G1-4330*.

### PSTATE.{A, I, F, M} values on exception entry

On exception entry, **PSTATE**.M is set to the value for the mode to which the exception is taken, as described in *PE mode for taking exceptions on page G1-4350*.

Table G1-13 shows the cases where **PSTATE**.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and Security state to which an exception is taken. If the table entry for a particular mode and Security state does not define a value for a **PSTATE**.{A, I, F} bit then that bit is unchanged by the exception entry. In this table:

- The *Exception mode* column is the mode to which the exception is taken.
- The *Non-secure, EL2 not implemented* column applies to exceptions taken to Non-secure state in an implementation that includes EL3 but does not include EL2.
- The *All others* column applies to:
  - Exceptions taken to Secure state.
  - Implementations that do not include the EL3.
  - Exceptions taken to Non-secure state in an implementation that includes EL2.

Table G1-13 **PSTATE**.{A, I, F} values on exception entry

PE mode exception is taken to	Security state	
	Non-secure	Secure
Hyp	If <b>SCR</b> .EA==0 then <b>PSTATE</b> .A is set to 1 If <b>SCR</b> .IRQ==0 then <b>PSTATE</b> .I is set to 1 If <b>SCR</b> .FIQ==0 then <b>PSTATE</b> .F is set to 1	-
Monitor	-	<b>PSTATE</b> .A is set to 1 <b>PSTATE</b> .I is set to 1 <b>PSTATE</b> .F is set to 1

Table G1-13 **PSTATE**.{A, I, F} values on exception entry (continued)

PE mode exception is taken to	Security state	
	Non-secure	Secure
FIQ	<b>PSTATE.A</b> is set to 1 <b>PSTATE.I</b> is set to 1 <b>PSTATE.F</b> is set to 1	<b>PSTATE.A</b> is set to 1 <b>PSTATE.I</b> is set to 1 <b>PSTATE.F</b> is set to 1
IRQ, Abort	<b>PSTATE.A</b> is set to 1 <b>PSTATE.I</b> is set to 1	<b>PSTATE.A</b> is set to 1 <b>PSTATE.I</b> is set to 1
Undefined, Supervisor	<b>PSTATE.I</b> is set to 1	<b>PSTATE.I</b> is set to 1

*Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365* describes how, in some situations, the **PSTATE**.{A, I, F} bits mask the taking ofSError interrupts, IRQ interrupts, and FIQ interrupts.

### G1.12.6 Routing exceptions from Non-secure EL0 to EL2

#### ———— Note ————

The routing control described in this section permits a Non-secure state usage model where applications execute in User mode under a hypervisor, that executes in Hyp mode, without a Guest OS running at Non-secure EL1. This control applies when the PE is executing in Non-secure EL0 using AArch32 and either:

- EL2 is using AArch32 and the value of **HCR.TGE** is 1.
- EL2 is using AArch64 and the value of **HCR\_EL2.TGE** is 1.

In general, this section describes only the handling and reporting of exceptions that are taken to EL2 using AArch32 because the value of **HCR.TGE** is 1. *Exception entry on page D1-1799* describes the handling of exceptions that are taken to EL2 using AArch64 because the value of **HCR\_EL2.TGE** is 1.

If the PE is in Non-secure User mode, any exception that would otherwise be taken to Non-secure EL1 is taken to EL2 if either:

- EL2 is using AArch32 and the value of **HCR.TGE** is 1.  
In this case the exception is taken to Hyp mode, instead of to the default Non-secure mode for handling the exception. For more information see *Exception reporting when HCR.TGE routes an exception to EL2 using AArch32 on page G1-4357*.
- EL2 is using AArch64 and the value of **HCR\_EL2.TGE** is 1.  
In this case the exception is taken to EL2 using AArch64, see *Exception entry on page D1-1799*.

Any exception that is routed to Secure Monitor mode or to EL3 using AArch64 is unaffected by the value of **HCR.TGE** or **HCR\_EL2.TGE**.

When the value of **HCR.TGE** is 1, meaning TGE routing from Non-secure EL0 using AArch32 to EL2 using AArch32 applies:

- The **SCTLR.M** bit is treated as 0 for all purposes other than a direct read of the **SCTLR** register.
- Each of the **HCR**.{FMO, IMO, AMO} bits is treated as 1 for all purposes other than a direct read of the **HCR** register
- Each of the **HDCR**.{TDE, TDA, TDRA, TDOSA} bits is treated as 1 for all purposes other than a direct read of the **HDCR** register.
- An exception return to Non-secure EL1 is treated as an illegal exception return, see *Illegal return events from AArch32 state on page G1-4361*.

- All virtual interrupts, including any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts, are disabled.

## Exception reporting when HCR.TGE routes an exception to EL2 using AArch32

The following sections give more information about the behavior of synchronous exceptions that are routed to Hyp mode because the value of HCR.TGE is 1:

- *Undefined Instruction exception, when the value of HCR.TGE is 1.*
- *Supervisor Call exception, when the value of HCR.TGE is 1.*
- *Abort exceptions, when the value of HCR.TGE is 1.*
- *Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1 on page G1-4358.*

### Undefined Instruction exception, when the value of HCR.TGE is 1

When HCR.TGE is set to 1, if the PE is executing in Non-secure User mode and attempts to execute an UNDEFINED instruction, it takes the Hyp Trap exception, instead of an Undefined Instruction exception. On taking the Hyp Trap exception, the HSR reports an unknown reason for the exception, using the EC value 0x00. For more information see *Use of the HSR on page G4-4677*.

### Supervisor Call exception, when the value of HCR.TGE is 1

When HCR.TGE is set to 1, if the PE executes an SVC instruction in Non-secure User mode, the Supervisor Call exception generated by the instruction is taken to Hyp mode.

The HSR reports that entry to Hyp mode was because of a Supervisor Call exception, and:

- If the SVC is unconditional, takes for the imm16 value in the HSR:
  - A zero-extended 8-bit immediate value for the T32 SVC instruction.
- If the SVC is conditional, the imm16 value in the HSR is UNKNOWN.

#### ————— Note —————

The only T32 encoding for SVC is a 16-bit instruction encoding.

- The bottom16 bits of the immediate value for the A32 SVC instruction.

If the SVC is conditional, the PE takes the exception only if the instruction passes its Condition code check.

The HSR reports the exception as a Supervisor Call exception taken to Hyp mode, using the EC value 0x11. For more information, see *Use of the HSR on page G4-4677*.

#### ————— Note —————

The effect of setting HCR.TGE to 1 is to route the Supervisor Call exception to Hyp mode, not to trap the execution of the SVC instruction. This means that the preferred return address for the exception, when routed to Hyp mode in this way, is the instruction after the SVC instruction.

### Abort exceptions, when the value of HCR.TGE is 1

When the value of HCR.TGE is 1, if the PE is executing in Non-secure User mode then any abort exception that is not routed to Secure Monitor mode or to EL3 using AArch64 generates an exception that is taken as a Hyp Trap exception. Where an attempt to execute an instruction causes an abort, on taking the Hyp Trap exception, the HSR indicates whether a Data Abort exception or a Prefetch Abort exception caused the Hyp Trap exception entry, and presents a valid syndrome in the HSR.

When SCR.EA is set to 1, external aborts and SError interrupts are routed to EL3, and this routing takes priority over the HCR.TGE routing. For more information, see *Asynchronous exception routing controls on page G1-4367*. The SCR.EA control described in that section applies to both synchronous external aborts and asynchronous SError interrupts.

An SError interrupt that is routed to Hyp mode because the value of HCR.TGE is 1 is reported as a Data Abort exception routed to Hyp mode.

The [HSR](#) reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information about the exception reporting, see [Use of the HSR on page G4-4677](#).

#### Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1

[PL1 configurable controls on page G1-4419](#) describes controls that, when the value of HCR.TGE is 0, can generate exceptions that are taken from Non-secure EL0 to EL1. When EL2 is using AArch32 and the value of HCR.TGE is 1, the exceptions generated by these controls are routed to Hyp mode. [Table G1-14](#) shows how these exceptions are then reported in the [HSR](#).

**Table G1-14 Syndrome reporting in HSR from HCR.TGE routing of traps, disables, and enables**

Control provided by PL1	Control type <sup>a</sup>	Syndrome reporting in HSR
<a href="#">SCTLR</a> .{nTWE, nTWI}	T	Uses EC value 0x00, Exception for an unknown reason
<a href="#">SCTLR</a> .{SED, ITD}	D	Uses EC value 0x00, Exception for an unknown reason
<a href="#">SCTLR</a> .CP15BEN	E	Uses EC value 0x00, Exception for an unknown reason
<a href="#">CPACR</a> .TRCDIS	T	Uses EC value 0x00, Exception for an unknown reason
<a href="#">CPACR</a> .{cp11, cp10}	E	Uses EC value 0x00, Exception for an unknown reason
<a href="#">FPEXC</a> .EN	E	Uses EC value 0x00, Exception for an unknown reason
<a href="#">CPACR</a> .ASEDIS	D	Uses EC value 0x00, Exception for an unknown reason
<a href="#">DBGDSCRExt</a> .UDCCdis	T	Uses EC value 0x00, Exception for an unknown reason
<a href="#">CNTKCTL</a> .{PL0PTEN, PL0VTEN, PL0PCTEN, PL0VCTEN}	T	Uses EC value 0x00, Exception for an unknown reason
<a href="#">PMUSERENR</a> .{ER, CR, SW, EN}	T	Uses EC value 0x00, Exception for an unknown reason

- a. T indicates a trap control, E indicates an instruction enable, and D indicates an instruction disable. For the definition of these terms, see the list that begins with [Instruction enables and instruction disables on page G1-4418](#).

### G1.12.7 Routing debug exceptions to EL2 using AArch32

When the value of [HDCR](#).TDE is 1, if the PE is executing in a Non-secure mode other than Hyp mode, any Debug exception is routed to Hyp mode. This means it generates a Hyp Trap exception. This applies to:

- Debug exceptions associated with an instruction fetch, that would otherwise generate a Prefetch Abort exception. These are the Breakpoint, Breakpoint Instruction, and Vector Catch exception, see [Chapter G2 AArch32 Self-hosted Debug](#).
- Watchpoint exceptions associated with data accesses, that would otherwise generate a Data Abort exception. See [Watchpoint exceptions on page G2-4496](#).

When the value of [HDCR](#).TDE is 1, each of the [HDCR](#).{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than reading the [HDCR](#) register.

---

**Note**

---

- A Breakpoint or Watchpoint debug event that generates entry to Debug state cannot be trapped to Hyp mode. See [Breakpoint and Watchpoint debug events on page H2-5436](#).
- When [HDCR.TDE](#) is set to 1, the Hyp Trap exception is generated instead of the Prefetch Abort exception or Data Abort exception that is otherwise generated by the Debug exception.
- Debug exceptions, other than Breakpoint Instruction exceptions, are never generated in Hyp mode.

---

When a Hyp Trap exception is generated because the value of [HDCR.TDE](#) is 1, The [HSR](#) reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information see [Use of the HSR on page G4-4677](#).

## G1.13 Exception return to an Exception level using AArch32

In the ARM architecture, *exception return* to an Exception level that is using AArch32 requires the simultaneous restoration of the PC and [PSTATE](#) to values that are consistent with the desired state of execution on returning from the exception. Typically, exception return involves returning to one of:

- The instruction after the instruction boundary at which an asynchronous exception was taken.
- The instruction following an SVC, SMC, or HMC instruction, for an exception generated by one of those instructions.
- The instruction that caused the exception, after the reason for the exception has been removed.
- The subsequent instruction, if the instruction that caused the exception has been emulated in the exception handler.

The ARM architecture defines a *preferred return address* for each exception other than Reset, see [Link values saved on exception entry on page G1-4349](#). The values of the [SPSR.IT\[7:0\]](#) bits generated on exception entry are always correct for this preferred return address, but might require adjustment by the exception handler if returning elsewhere.

In some cases, to calculate the appropriate preferred return address for a return to an Exception level that is using AArch32, a subtraction must be performed on the link value saved on taking the exception. The description of each exception includes any value that must be subtracted from the link value, and other information about the required exception return.

On an exception return, the [PSTATE](#) takes either:

- The value loaded by the RFE instruction.
- If the exception return is not performed by executing an RFE instruction, the value of the current [SPSR](#) at the time of the exception return.

[Illegal return events from AArch32 state on page G1-4361](#) describes the behavior if the restored PE state would not be valid for the Exception level, PE mode, and Security state targeted by the exception return.

### G1.13.1 Exception return instructions

The instructions that an exception handler can use to return from an exception depend on whether the exception was taken to an EL1 mode, or in an EL2 mode, see:

- [Return from an exception taken to a PE mode other than Hyp mode.](#)
- [Return from an exception taken to Hyp mode on page G1-4361.](#)

#### Return from an exception taken to a PE mode other than Hyp mode

For an exception taken to a PE mode other than Hyp mode, the ARM AArch32 architecture provides the following *exception return instructions*:

- From privileged modes other than System mode, the ERET instruction. After the exception return, execution resumes from the address held in the LR (R14) for the mode in which ERET is executed. See [ERET on page F5-3117](#).
- Data-processing instructions with the S bit set and the PC as a destination, see [MOV, MOVS \(register\) on page F5-3260](#) and [SUB, SUBS \(immediate\) on page F5-3560](#).

#### ————— Note —————

The A32 instruction set includes other instructions that can be used for an exception return, but ARM deprecates any use of those instructions.

Typically:

- A return where no subtraction is required uses SUBS with an operand of 0, or the equivalent MOVN instruction.
- A return requiring subtraction uses SUBS with a nonzero operand.
- The RFE instruction, see [RFE, RFEDA, RFEDB, RFEIA, RFEIB](#) on page F5-3363. If a subtraction is required, typically it is performed before saving the LR value to memory. After the exception return, execution resumes from the address held in the memory location indicated by the base register specified by the RFE instruction.
- In A32 state, a form of the LDM instruction in which the PC is one of the registers loaded, see [LDM \(exception return\)](#) on page F5-3148. If a subtraction is required, typically it is performed before saving the LR value to memory.

## Return from an exception taken to Hyp mode

For an exception taken to Hyp mode, the ARM architecture provides the ERET instruction, see [ERET](#) on page F5-3117. An exception handler executing in Hyp mode must return using the ERET instruction.

Both Hyp mode and the ERET instruction are implemented only as part of EL2.

### G1.13.2 Alignment of exception returns

The T bit of the value transferred to the [PSTATE](#) by an exception return controls the target instruction set of that return. The behavior of the hardware for exception returns for different values of the T bit is as follows:

- T == 0**      The target instruction set state is A32 state. Bits[1:0] of the address transferred to the PC are ignored by the hardware.
- T == 1**      The target instruction set state is T32 state:
- Bit[0] of the address transferred to the PC is ignored by the hardware.
  - Bit[1] of the address transferred to the PC is part of the instruction address.

#### ———— Note —————

In previous versions of the ARM architecture, the [PSTATE](#).{J, T} bits determined the Instruction set state. In ARMv8, [PSTATE](#).J is RES0.

ARM deprecates any dependence on the requirements that the hardware ignores bits of the address. ARM recommends that the address transferred to the PC for an exception return is correctly aligned for the target instruction set.

After an exception entry other than Reset, the LR value has the correct alignment for the instruction set indicated by the [SPSR](#).T bit. This means that if exception return instructions are used with the LR and [SPSR](#) values produced by such an exception entry, the only precaution software needs to take to ensure correct alignment is that any subtraction is of a multiple of four if returning to A32 state, or a multiple of two if returning to T32 state.

### G1.13.3 Illegal return events from AArch32 state

Throughout this section:

- Return**      In AArch32 state, refers to any of:
- Execution of any exception return instruction.
  - Execution of a DRPS instruction in Debug state.
  - Exit from Debug state.
- If an exception or debug return from an Exception level using AArch32 triggers an illegal exception return, then bit[1] of the PC is either:
- Zero.
  - The value of bit[1] of the return address for the exception or debug return.

The choice between these two alternatives is made by the implementation, and might differ from instance to instance of an illegal exception return.

**Note**

This means software must support both alternatives.

**Saved process state value**

In AArch32 state, refers to any of:

- The value held in the [SPSR](#) for any exception return other than an exception return made by executing an RFE instruction.
- The value read from memory that is to be restored to [PSTATE](#) by the execution of an RFE instruction.
- The value held in the [SPSR](#) for the execution of a DRPS instruction in Debug state.
- The value held in the [DSPSR](#) for a Debug state exit.

**Link address** In AArch32 state, refers to any of:

- The address held in the link register for any exception return other than an exception return made by executing an ERET, LDM, or RFE instruction.
- The address held in [ELR\\_hyp](#) for any exception return made by executing an ERET instruction.
- The address read from memory that is to be restored to the PC by the execution of an LDM or RFE instruction.
- The address held in the [DLR](#) for Debug state exit.

**Configured from reset**

Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling exception or debug returns to a mode or state that is illegal. In AArch32 state, this can occur as a result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the mode being returned to is not implemented. For example:
  - A return to Hyp mode when EL2 is not implemented.
  - A return to Monitor mode, when EL3 is either not implemented or using AArch64 state.
- A return to EL2 when:
  - EL3 is implemented and using AArch64, and the value of the [SCR\\_EL3.NS](#) bit is 0.
  - EL3 is implemented and using AArch32, and the value of the [SCR.NS](#) bit is 0.
- A return to Non-secure EL1 when:
  - EL2 is implemented and using AArch64, and the value of the [HCR\\_EL2.TGE](#) bit is 1.
  - EL2 is implemented and using AArch32, and the value of the [HCR.TGE](#) bit is 1.
- A return where the value of the saved process state M[4:0] field is not a valid AArch32 PE mode for the implementation. [Table G1-5 on page G1-4322](#) shows the valid M[4:0] values for AArch32 PE modes.

In these cases:

- [PSTATE.IL](#) is set to 1, to indicate an illegal return.
- [PSTATE.M](#) is unchanged. This means the PE mode does not change.
- The SS bit is handled in the same way as any other exception or debug return, see [Software Step exceptions on page D2-1956](#).

- The following **PSTATE** bits are restored from the saved process state value:
  - The N, Z, C, V Condition flags.
  - The Q Overflow or saturation flag.
  - The GE Greater than or Equal flags.
  - The E Endianness mapping bit.
  - The A, I, F exception mask bits.
- The **PSTATE**.{IT, T} bits are each either:
  - Set to 0.
  - Copied from the saved process state in the **SPSR** for the PE mode in which the exception is handled.The choice between these two options is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.
- The PC is restored from the link address, unless the illegal return is the execution of a DRPS instruction in Debug state.

When the value of the **PSTATE**.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See *The Illegal Execution state exception*.

All aspects of the illegal return, other than the effects described in this section, are the same as for a legal return.

#### G1.13.4 Legal returns that set **PSTATE**.IL to 1

In this section, return, saved process state value, and link address have the meaning that is defined in *Illegal return events from AArch32 state on page G1-4361*.

If the IL bit in the saved process state value is 1, then it is copied to **PSTATE** meaning that **PSTATE**.IL is set to 1. In this case, the **PSTATE**.{IT, T} bits are each either:

- Set to 0.
- Copied from the **SPSR**, or loaded from memory if the exception return was performed by executing an RFE instruction.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. This means software must regard each value as being an UNKNOWN choice between the two permitted values.

Because the return sets the **PSTATE**.IL bit to 1, any attempt to execute any instruction results in an Illegal Execution state exception. See *The Illegal Execution state exception*.

#### G1.13.5 The Illegal Execution state exception

When the value of the **PSTATE**.IL bit is 1, any attempt to execute an instruction generates an Illegal Execution state exception. In AArch32 state, the **PSTATE**.IL bit can be set to 1 by one of the following:

- An illegal return, as described in *Illegal return events from AArch32 state on page G1-4361*.
- An illegal change to **PSTATE**.M, as described in *Illegal changes to PSTATE.M on page G1-4336*.
- A legal return that sets **PSTATE**.IL to 1, as described in *Legal returns that set PSTATE.IL to 1*.

An Illegal Execution state exception is taken in the same way as an Undefined Instruction exception in the current Exception level. If the current Exception level is EL2 using AArch32 state, the **HSR** provides additional syndrome information for the exception, see *Use of the HSR on page G4-4677*.

An Illegal Execution state exception has priority over any other Undefined Instruction exception that might arise from instruction execution.

---

**Note**

---

This section only describes the handling of an Illegal Execution state exception that is taken to an Exception level that is using AArch32 state. *The Illegal Execution state exception on page D1-1818* describes the cases where an Illegal Execution state exception is taken to an Exception level that is using AArch64 state.

---

On taking any exception to an Exception level that is using AArch32 state:

1. The value of the `PSTATE.IL` bit is 1 and this is copied to the `SPSR.IL` bit for the PE mode to which the exception is taken.
2. The `PSTATE.IL` bit is cleared to 0.

---

**Note**

---

This means that it is not possible for software to observe the value of `PSTATE.IL`.

---

### Pseudocode description of exception return

The `AArch32.ExceptionReturn()` function transfers the return address to the PC and restores `PSTATE` to its saved value.

This function uses the function `SetPSTATEFromPSR()`.

The `IllegalExceptionReturn()` function checks for an Illegal Execution state exception.

*Chapter J1 ARMv8 Pseudocode* includes the definitions of these functions.

## G1.14 Asynchronous exception behavior for exceptions taken from AArch32 state

In an implementation that does not include EL2 or EL3, the asynchronous exceptions behave as follows when EL1 and EL0 are both using AArch32:

- An SError interrupt is taken to Abort mode.
- An IRQ exception is taken to IRQ mode.
- An FIQ exception is taken to FIQ mode.

These are the *default PE modes* for taking these exceptions.

### ———— Note ————

The SError interrupt replaces the ARMv7 asynchronous abort. The new name better describes the nature of the exception.

However, the `PSTATE`.{A, I, F} bits *mask* the asynchronous exceptions, meaning that when the value of one of these `PSTATE` bits is 1, the corresponding exception is not taken.

If a masked asynchronous exceptions remains signaled, then the exception remains pending unless the value of the `PSTATE` bit is changed to 0.

EL2 and EL3 provide controls that affect:

- The routing of these exceptions, see [Asynchronous exception routing controls on page G1-4367](#).
- Masking of these exceptions in Non-secure state, see [Asynchronous exception masking controls on page G1-4368](#).

Similar register control bits are provided regardless of whether EL2 and EL3 are using AArch32 or AArch64:

- The EL2 controls are provided by the `HCR` when EL2 is using AArch32, and by the `HCR_EL2` when EL2 is using AArch64.
- The EL3 controls are provided by the `SCR` when EL3 is using AArch32, and by the `SCR_EL3` when EL3 is using AArch64.

Therefore, most references to the `HCR` or `SCR` in this section are to entries in [Table K11-1 on page K11-6282](#), that disambiguates between AArch32 registers and AArch64 registers. However, the Execution states used by EL2 and EL3 do affect some aspects of the routing and masking of the asynchronous exceptions, see [Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-4370](#).

### G1.14.1 Virtual exceptions when an implementation includes EL2

When implemented, EL2 provides the following virtual exceptions, that correspond to the physical asynchronous exceptions:

- Virtual SError, that corresponds to a physical external SError interrupt.
- Virtual IRQ, that corresponds to a physical IRQ.
- Virtual FIQ, that corresponds to a physical FIQ.

When the value of `HCR`.TGE is 0 and the value of an `HCR`.{AMO, IMO, FMO} routing control bit is 1, the corresponding virtual interrupt is enabled and a virtual exception is generated either:

- By setting the corresponding virtual interrupt pending bit, `HCR`.{VA, VI, VF}, to 1.
- For a Virtual IRQ or Virtual FIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the *ARM Generic Interrupt Controller Architecture Specification*.

When the value of `HCR_EL2`.TGE is 1 all virtual interrupts are disabled.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the `ISR`.

In AArch32 state, a virtual exception is taken only from a Non-secure EL1 or EL0 mode. In any other mode, if the exception is generated it is not taken.

A virtual exception is taken in Non-secure state to the default mode for the corresponding physical exception. This means:

- A Virtual SError is taken to Non-secure Abort mode.
- A Virtual IRQ is taken to Non-secure IRQ mode.
- A Virtual FIQ is taken to Non-secure FIQ mode.

**Table G1-15** summarizes the **HCR** bits that route asynchronous exceptions to EL2, and the bits that generate the virtual exceptions.

**Table G1-15 HCR bits controlling asynchronous exceptions**

Exception	Routing the physical exception to EL2	Generating the virtual exception
SError	<a href="#">HCR.AMO</a>	<a href="#">HCR.VA</a>
IRQ	<a href="#">HCR.IMO</a>	<a href="#">HCR.VI</a>
FIQ	<a href="#">HCR.FMO</a>	<a href="#">HCR.VF</a>

The **HCR**.{VA, VI, VF} bits generate a virtual exception only if set to 1 when the value of the corresponding **HCR**.{AMO, IMO, FMO} is 1.

Similarly, if the implementation also includes EL3, the **HCR**.{AMO, IMO, FMO} bits route the corresponding physical exception to Hyp mode only if the physical exception is not routed to Monitor mode by the **SCR**.{EA, IRQ, FIQ} bit. For more information, see *Asynchronous exception routing controls* on page G1-4367.

When the value of an **HCR**.{AMO, IMO, FMO} control bit is 1, the corresponding mask bit in **PSTATE**:

- Does not mask the physical exception.
- Masks the virtual exception when the PE is executing in a Non-secure EL1 or EL0 mode.

Taking a Virtual Abort exception clears **HCR.VA** to zero. Taking a Virtual IRQ exception or a Virtual FIQ exception does not affect the value of **HCR.VI** or **HCR.VF**.

#### ———— **Note** ————

This means that the exception handler for a Virtual IRQ exception or a Virtual FIQ exception must cause software that is executing at EL2 or EL3 to update the **HCR** to clear the appropriate virtual exception bit to 0.

See *WFE wake-up events* on page G1-4405 and *Wait For Interrupt* on page G1-4406 for information about how virtual exceptions affect wake up from power-saving states.

#### ———— **Note** ————

A hypervisor can use virtual exceptions to signal exceptions to the current Guest OS. The Guest OS takes a virtual exception exactly as it would take the corresponding physical exception, and is unaware of any distinction between virtual exception and the corresponding physical exception.

### Effects of the **HCR**.{AMO, IMO, FMO} bits

As described in this section, the **HCR**.{AMO, IMO, FMO} bits are part of the mechanism for enabling the virtual exceptions. In addition, for exceptions generated in Non-secure state:

- As mentioned in this section, affect the routing of the exceptions. See *Asynchronous exception routing controls* on page G1-4367.
- Affect the masking of the exceptions. See *Asynchronous exception masking controls* on page G1-4368.

## G1.14.2 Asynchronous exception routing controls

---

### Note

---

This section describes the behavior when all Exception levels are using AArch32. For the differences when this is not the case see [Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-4370](#).

---

In an implementation that includes EL3 the following bits in the **SCR** control the routing of asynchronous exceptions, and also the routing of synchronous external aborts:

**SCR.EA** When the value of this bit is 1, any synchronous external abort or SError interrupt is taken to EL3.

---

### Note

---

- Although this section describes the asynchronous exception routing controls, **SCR.EA** controls the routing of both synchronous external aborts and asynchronous SError interrupts.
  - The other classes of abort cannot be routed to EL3. For more information about the classification of aborts, see [VMSAv8-32 memory aborts on page G4-4649](#).
- 

**SCR.FIQ** When the value of this bit is 1, any FIQ exception is taken to EL3.

**SCR.IRQ** When the value of this bit is 1, any IRQ exception is taken to EL3.

When EL3 is using AArch32 and the value of one of the **SCR**.{EA, FIQ, IRQ} bits is 1, the exception is taken to Monitor mode.

Only Secure software can change the values of these bits.

In an implementation that includes EL2, the following bits in the **HCR** route asynchronous exceptions to EL2, for exceptions that are both:

- Taken from a Non-secure EL1 or EL0 mode.
- If the implementation also includes EL3, not configured, by the **SCR**.{EA, FIQ, IRQ} controls, to be taken to EL3.

**HCR.AMO** When the value of this bit is 1, an SError interrupt exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure Abort mode. If the implementation also includes EL3, this control applies only if the value of **SCR.EA** is 0. When the value of **SCR.EA** is 1, the value of the AMO bit is ignored.

**HCR.FMO** When the value of this bit is 1, an FIQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure FIQ mode. If the implementation also includes EL3, this control applies only if the value of **SCR.FIQ** is 0. When the value of **SCR.FIQ** is 1, the value of the FMO bit is ignored.

**HCR.IMO** When the value of this bit is 1, an IRQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure IRQ mode. If the implementation also includes EL3, this control applies only if the value of **SCR.IRQ** is 0. When the value of **SCR.IRQ** is 1, the value of the IMO bit is ignored.

When EL2 is using AArch32 and the value of one of the **HCR**.{AMO, FMO, IMO} bits is 1, the exception is taken to Hyp mode.

Only software executing in Hyp mode, or Secure software executing at EL3 with **SCR.NS** set to 1, can change the values of these bits. If EL3 is using AArch32, this requires the Secure software to be executing in Monitor mode.

The **HCR**.{AMO, FMO, IMO} bits also affect the masking of asynchronous exceptions in Non-secure state, as described in [Asynchronous exception masking controls on page G1-4368](#).

The **SCR**.{EA, FIQ, IRQ} and **HCR**.{AMO, FMO, IMO} bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.

---

**Note**

---

When the PE is in Hyp mode:

- Physical asynchronous exceptions that are not routed to Monitor mode are taken to Hyp mode.
- Virtual exceptions are not signaled to the PE.

---

See also [Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-4365](#).

### G1.14.3 Asynchronous exception masking controls

---

**Note**

---

This section describes the behavior when all Exception levels are using AArch32. For the differences when this is not the case see [Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-4370](#).

The **PSTATE**.{A, I, F} bits can mask the taking of the corresponding exceptions from AArch32 state, as follows:

- **PSTATE**.A can mask SError interrupt exceptions.
- **PSTATE**.I can mask IRQ exceptions.
- **PSTATE**.F can mask FIQ exceptions.

In an implementation that does not include either of EL2 and EL3, setting one of these bits to 1 masks the corresponding exception, meaning the exception cannot be taken.

In an implementation that includes EL2, the **HCR**.{AMO, IMO, FMO} bits modify the masking of exceptions taken from Non-secure state.

Similarly, in an implementation that includes EL3, the **SCR**.{AW, FW} bits modify the masking of exceptions taken from Non-secure state by the **PSTATE**.{A, F} bits.

An implementation that includes only EL1 and EL0 does not provide any masking of the **PSTATE**.{A, I, F} bits. The following subsections describe the masking of these bits in other implementations:

- [Asynchronous exception masking in an implementation that includes EL2 but not EL3](#).
- [Asynchronous exception masking in an implementation that includes EL3 but not EL2](#).
- [Asynchronous exception masking in an implementation that includes both EL2 and EL3 on page G1-4369](#).
- [Summary of the asynchronous exception masking controls on page G1-4369](#).

#### Asynchronous exception masking in an implementation that includes EL2 but not EL3

The **HCR**.{AMO, IMO, FMO} bits modify the effect of the **PSTATE**.{A, I, F} bits. When the value of an **HCR**.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding **PSTATE**.{A, I, F} bit is ignored when the exception is taken from a Non-secure mode other than Hyp mode.

#### Asynchronous exception masking in an implementation that includes EL3 but not EL2

The **SCR**.{AW, FW} bits modify the effect of the **PSTATE**.{A, F} bits. When the value of one of the **SCR**.{AW, FW} bits is 0, the corresponding **PSTATE** bit is ignored when both of the follow apply:

- The corresponding exception is taken from Non-secure state.
- The value of the corresponding **SCR**.{EA, FIQ} bit is 1, routing the exception to EL3. This means the exception is routed to Monitor mode if EL3 is using AArch32.

---

**Note**

---

Whenever the value of **PSTATE**.I is 1, IRQ exceptions are masked and cannot be taken.

### Asynchronous exception masking in an implementation that includes both EL2 and EL3

When the value of an [HCR](#).{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding [PSTATE](#).{A, I, F} bit is ignored when both of the following apply:

- The exception is taken from Non-secure state.
- Either:
  - The corresponding [SCR](#).{EA, IRQ, FIQ} bit routes the exception to Monitor mode.
  - The exception is taken from a Non-secure mode other than Hyp mode.

In addition, when the value of an [SCR](#).{AW, FW} bit is 0, the value of the corresponding [PSTATE](#).{A, F} bit is ignored when all of the following apply:

- The exception is taken from Non-secure state.
- The corresponding [SCR](#).{EA, FIQ} bit routes the exception to Monitor mode.
- The corresponding [HCR](#).{AMO, FMO} mask override bit is set to 0.

### Summary of the asynchronous exception masking controls

The tables in this section show the masking controls for each of the [PSTATE](#).{A, I, F} bits. For an implementation that does not include all of the Exception levels:

#### If the implementation includes only EL1 and EL0

The [PSTATE](#) bits cannot be masked. The behavior is as shown in the *Secure* row of the tables.

#### If the implementation includes EL2 but not EL3

The behavior is as shown in the *Non-secure* table rows when the control bits in the [SCR](#) are both 0.

#### If the implementation includes EL3 but not EL2

The behavior is as shown in the table rows where the control bit in the [HCR](#) is 0.

[Table G1-16](#) shows the controls of the masking of SError interrupt exceptions by [PSTATE](#).A.

**Table G1-16 Control of masking by [PSTATE](#).A**

Security state	<a href="#">HCR</a> .AMO	<a href="#">SCR</a> .EA	<a href="#">SCR</a> .AW	Mode	<a href="#">PSTATE</a> .A
Secure	x	x	x	x	Masks SError interrupt, when set to 1
Non-secure	0	0	x	x	Masks SError interrupt, when set to 1
		1	0	x	Ignored
			1	x	Masks SError interrupt, when set to 1
	1	x	x	Not Hyp	Ignored
		0	x	Hyp	Masks SError interrupt, when set to 1
		1	x	x	Ignored

Table G1-17 shows the controls of the masking of FIQ exceptions by [PSTATE.F](#):

**Table G1-17 Control of masking by [PSTATE.I](#)**

Security state	<a href="#">HCR.IMO</a>	<a href="#">SCR.IRQ</a>	Mode	<a href="#">PSTATE.I</a>
Secure	x	x	x	Masks IRQs, when set to 1
Non-secure	0	x	x	Masks IRQs, when set to 1
		1	Not Hyp	Ignored
	1	0	Hyp	Masks IRQs, when set to 1
		1	x	Ignored

Table G1-18 shows the controls of the masking of FIQ exceptions by [PSTATE.F](#):

**Table G1-18 Control of masking by [PSTATE.F](#)**

Security state	<a href="#">HCR.FMO</a>	<a href="#">SCR.FIQ</a>	<a href="#">SCR.FW</a>	Mode	<a href="#">PSTATE.F</a>
Secure	x	x	x	x	Masks FIQs, when set to 1
Non-secure	0	0	x	x	Masks FIQs, when set to 1
		1	0	x	Ignored
			1	x	Masks FIQs, when set to 1
	1	x	x	Not Hyp	Ignored
		0	x	Hyp	Masks FIQs, when set to 1
		1	x	x	Ignored

#### G1.14.4 Asynchronous exception routing and masking with higher Exception levels using AArch64

[Asynchronous exception routing controls](#) on page G1-4367 and [Asynchronous exception masking controls](#) on page G1-4368 give full descriptions of the routing and masking of the asynchronous exceptions when all Exception levels are using AArch32. However, when EL0 and EL1 are using AArch32:

- As already described, the [SCR](#) and [HCR](#) controls might be from Exception levels that are using AArch64.
- If EL3 is using AArch64, or EL2 is using AArch64, there are some changes to the asynchronous exception behaviors.

Therefore, the following sections summarize the asynchronous exception behaviors, taking account of the Execution state being used at EL2 and EL3:

- [Summary of physical interrupt routing](#).
- [Summary of physical interrupt masking](#) on page G1-4372.

#### Summary of physical interrupt routing

The following tables show the routing of physical interrupts. [Table G1-19 on page G1-4371](#) shows the routing of physical FIQ interrupts, [Table G1-20 on page G1-4371](#) shows the routing of physical IRQ interrupts, and [Table G1-21 on page G1-4372](#) shows the routing of physical SError interrupts.

In these tables, for exceptions that must be taken to an Exception level that is using AArch32, the table shows the target Exception level and PE mode. In these entries, *Mon* indicates Monitor mode, and *Abt* indicates Abort mode.

Table G1-19 Routing of physical FIQ exceptions

EL3 Execution state	Control bits			Target when take from:					
	SCR	HCR		Non-secure			Secure		
	FIQ	RW <sup>a</sup>	FMO <sup>b</sup>	EL0	EL1	EL2	EL0	EL1 <sup>c</sup>	EL3
AArch32	0	x	0	EL1 FIQ	EL1 FIQ	EL2 Hyp	EL3 FIQ	-	EL3 FIQ
			1	EL2 Hyp	EL2 Hyp	EL2 Hyp	EL3 FIQ	-	EL3 FIQ
	1	x	x	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
AArch64	0	0	0	EL1 FIQ	EL1 FIQ	EL2 Hyp	EL1 FIQ	EL1 FIQ	P <sup>d</sup>
		x	1	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL1 <sup>f</sup>	EL1 <sup>f</sup>	P <sup>d</sup>
		1	0	EL1	EL1	P <sup>d</sup>	EL1	EL1	P <sup>d</sup>
	1	x	x	EL3	EL3	EL3	EL3	EL3	EL3

- a. [SCR\\_EL3.RW](#). When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.  
b. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.  
c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.  
d. Interrupt is not taken, but remains pending.  
e. If EL2 is using AArch32, taken to Hyp mode.  
f. If EL1 is using AArch32, taken to Abort mode.

Table G1-20 Routing of physical IRQ exceptions

EL3 Execution state	Control bits			Target when take from:					
	SCR	HCR		Non-secure			Secure		
	IRQ	RW <sup>a</sup>	IMO <sup>b</sup>	EL0	EL1	EL2	EL0	EL1 <sup>c</sup>	EL3
AArch32	0	x	0	EL1 IRQ	EL1 IRQ	EL2 Hyp	EL3 IRQ	-	EL3 IRQ
			1	EL2 Hyp	EL2 Hyp	EL2 Hyp	EL3 IRQ	-	EL3 IRQ
	1	x	x	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
AArch64	0	0	0	EL1 IRQ	EL1 IRQ	EL2 Hyp	EL1 IRQ	EL1 IRQ	P <sup>d</sup>
		x	1	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL1 <sup>f</sup>	EL1 <sup>f</sup>	P <sup>d</sup>
		1	0	EL1	EL1	P <sup>d</sup>	EL1	EL1	P <sup>d</sup>
	1	x	x	EL3	EL3	EL3	EL3	EL3	EL3

- a. [SCR\\_EL3.RW](#). When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.  
b. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.  
c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.  
d. Interrupt is not taken, but remains pending.  
e. If EL2 is using AArch32, taken to Hyp mode.

f. If EL1 is using AArch32, taken to Abort mode.

**Table G1-21 Routing of physical SError interrupts**

EL3 Execution state	Control bits			Target when take from:					
	SCR		HCR	Non-secure			Secure		
	EA	RW <sup>a</sup>	AMO <sup>b</sup>	EL0	EL1	EL2	EL0	EL1 <sup>c</sup>	EL3
AArch32	0	x	0	EL1 Abt	EL1 Abt	EL2 Hyp	EL3 Abt	-	EL3 Abt
			1	EL2 Hyp	EL2 Hyp	EL2 Hyp	EL3 Abt	-	EL3 Abt
	1	x	x	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
AArch64	0	0	0	EL1 Abt	EL1 Abt	EL2 Hyp	EL1 Abt	EL1Abt	p <sup>d</sup>
		x	1	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL1 <sup>f</sup>	EL1 <sup>f</sup>	p <sup>d</sup>
		1	0	EL1	EL1	p <sup>d</sup>	EL1	EL1	p <sup>d</sup>
	1	x	x	EL3	EL3	EL3	EL3	EL3	EL3

a. [SCR\\_EL3.RW](#). When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.

b. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.

c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

d. Interrupt is not taken, but remains pending.

e. If EL2 is using AArch32, taken to Hyp mode.

f. If EL1 is using AArch32, taken to Abort mode.

## Summary of physical interrupt masking

The following tables show the masking of physical interrupts. [Table G1-22 on page G1-4373](#) shows the masking of physical FIQ interrupts, [Table G1-23 on page G1-4373](#) shows the masking of physical IRQ interrupts, and [Table G1-24 on page G1-4374](#) shows the masking of physical SError interrupts. In these tables:

- M** Indicates that the exception is masked when the value of the [PSTATE](#) mask bit is 1.
- T** Indicates that the exception is taken, regardless of the value of the [PSTATE](#) mask bit.
- P** Indicates that the exception is not taken but remains pending. The value of the [PSTATE](#) mask bit has no effect on this behavior.

Table G1-22 Masking of physical FIQ exceptions

EL3 Execution state	Control bits			Effect of <b>PSTATE.F</b> <sup>a</sup> mask in Exception level						
	<b>SCR</b>	<b>FW</b>	<b>RW<sup>b</sup></b>	<b>HCR</b>	Non-secure			Secure		
					<b>EL0</b>	<b>EL1</b>	<b>EL2</b>	<b>EL0</b>	<b>EL1<sup>d</sup></b>	<b>EL3</b>
AArch32	0	x	x	0	M	M	M	M	-	M
				1	T	T	M	M	-	M
	1	0	x	0	T	T	T	M	-	M
			1	0	M	M	M	M	-	M
		x	x	1	T	T	T	M	-	M
	AArch64	0	x	0	M	M	M	M	M	P
				1	T	T	M	M	M	P
				0	M	M	P	M	M	P
				1	T	T	M	M	M	P
		1	x	x	T	T	T	T	T	M

- a. In AArch32 state this is visible as **CPSR.F**.  
b. **SCR\_EL3** only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.  
c. When the value of **HCR.TGE** is 1, the effective value of this bit is 1.  
d. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

Table G1-23 Masking of physical IRQ exceptions

EL3 Execution state	Control bits			Effect of <b>PSTATE.I</b> <sup>a</sup> mask in Exception level						
	<b>SCR</b>	<b>IRQ</b>	<b>RW<sup>b</sup></b>	<b>HCR</b>	Non-secure			Secure		
					<b>EL0</b>	<b>EL1</b>	<b>EL2</b>	<b>EL0</b>	<b>EL1<sup>d</sup></b>	<b>EL3</b>
AArch32	0	x	x	0	M	M	M	M	-	M
				1	T	T	M	M	-	M
	1	x	x	0	M	M	M	M	-	M
				1	T	T	T	M	-	M
AArch64	0	0	x	0	M	M	M	M	M	P
				1	T	T	M	M	M	P
				0	M	M	P	M	M	P
				1	T	T	M	M	M	P
	1	x	x	x	T	T	T	T	T	M

- In AArch32 state this is visible as [CPSR.I](#).
- [SCR\\_EL3](#) only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
- When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.
- When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

**Table G1-24 Masking of physical SError interrupts**

EL3 Execution state	Control bits				Effect of <b>PSTATE.A</b> <sup>a</sup> mask in Exception level							
	<b>SCR</b>				<b>HCR</b>	Non-secure			Secure			
		<b>EA</b>	<b>AW</b>	<b>RW<sup>b</sup></b>		<b>AMO<sup>c</sup></b>	<b>EL0</b>	<b>EL1</b>	<b>EL2</b>	<b>EL0</b>	<b>EL1<sup>d</sup></b>	<b>EL3</b>
AArch32	0	x	x	0	M	M	M	M	-	M		
				1	T	T	M	M	-	M		
	1	0	x	0	T	T	T	M	-	M		
		1	x	0	M	M	M	M	-	M		
		x	x	1	T	T	T	M	-	M		
AArch64	0	x	0	0	M	M	M	M	M	P		
				1	T	T	M	M	M	M	P	
				1	0	M	M	P	M	M	M	P
					1	T	T	M	M	M	M	P
	1	x	x	x	T	T	T	T	T	M		

- In AArch32 state this is visible as [CPSR.A](#).
- [SCR\\_EL3](#) only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
- When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.
- When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

### G1.14.5 Taking an interrupt or other exception during a multiple-register load or store

In AArch32 state in ARMv8.0 and ARMv8.1, an interrupt cannot be taken during a sequence of memory accesses caused by a single load or store instruction.

When ARMv8.2-LSMAOC is implemented, an interrupt is permitted during a sequence of memory accesses generated by a LDM or STM instruction. Two control bits are added to HSCTLR and SCTLr to control this behavior. These are:

- The LSMAOE bit. This indicates that LDM and STM are permitted to be reordered or interrupted in any memory type.
- The nTLSMD bit. This causes LDM and STM instructions accessing Device memory to cause an Alignment fault.

When the LSMAOE bit is 0, if an interrupt is taken within the sequence of memory accesses generated by an LDM or STM instruction, then:

- For a load, any register being loaded by the instruction other than ones used in the generation of the address by the instruction, or PC, can contain an UNKNOWN value. Registers used in the generation of the address are restored to their initial value and the LR is set on the interrupt to a value consistent with returning to the instruction.
- For a store, any data location being stored to by the instruction can contain an UNKNOWN value.
- For either a load or store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.

## G1.15 AArch32 state exception descriptions

*Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340* gives general information about exception handling. This section describes each of the exceptions, in the following subsections:

- *Undefined Instruction exception.*
- *Monitor Trap exception on page G1-4379.*
- *Hyp Trap exception on page G1-4379.*
- *Supervisor Call (SVC) exception on page G1-4380.*
- *Secure Monitor Call (SMC) exception on page G1-4382.*
- *Hypervisor Call (HVC) exception on page G1-4383.*
- *Prefetch Abort exception on page G1-4384.*
- *Data Abort exception on page G1-4387.*
- *VirtualSError interrupt exception on page G1-4391.*
- *IRQ exception on page G1-4392.*
- *Virtual IRQ exception on page G1-4394.*
- *FIQ exception on page G1-4395.*
- *Virtual FIQ exception on page G1-4397.*

*Additional pseudocode functions for exception handling on page G1-4398* gives additional pseudocode that is used in the pseudocode descriptions of a number of the exceptions.

### G1.15.1 Undefined Instruction exception

An Undefined Instruction exception might be caused by:

- A System register access, floating-point, or Advanced SIMD instruction that is not accessible because of the settings in one or more of the [CPACR](#), [NSACR](#), [HCPTR](#), and [DBGDSCRext](#).
- A System register access, floating-point, or Advanced SIMD instruction that is not implemented.
- A System register access, floating-point, or Advanced SIMD instruction that causes an exception during execution. This includes:
  - Trapped floating-point exceptions that are taken to AArch32, if an implementation supports these traps. See [Floating-point exceptions and exception traps on page E1-2743](#).
  - Execution of certain floating-point instructions when one or both of the [FPSCR](#).{Stride, Len} fields in nonzero, in an implementation in which those fields are RW. The description of [FPEXC](#) specifies the instructions to which this applies.
- An instruction that is UNDEFINED.

#### ———— Note —————

The Undefined Instruction exception is taken using offset 0x04 in the Hyp, Secure, or Non-secure vector table. In the Monitor vector table this offset is used for the Monitor Trap exception. See [Monitor Trap exception on page G1-4379](#) and [The vector tables and exception offsets on page G1-4341](#).

By default, an Undefined Instruction exception is taken to Undefined mode, but an Undefined Instruction exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see [The PE mode to which the Undefined Instruction exception is taken on page G1-4377](#).

The Undefined Instruction exception can provide:

- Signaling of an illegal instruction execution.
- *Lazy context switching* of System registers.

The preferred return address for an Undefined Instruction exception is the address of the instruction that generated the exception. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from Secure or Non-secure Undefined mode, the exception return uses the [SPSR](#) and [LR\\_und](#) values generated by the exception entry, as follows:
  - If [SPSR.T](#) is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
  - If [SPSR.T](#) is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the [SPSR](#) and [ELR\\_hyp](#) values generated by the exception entry.

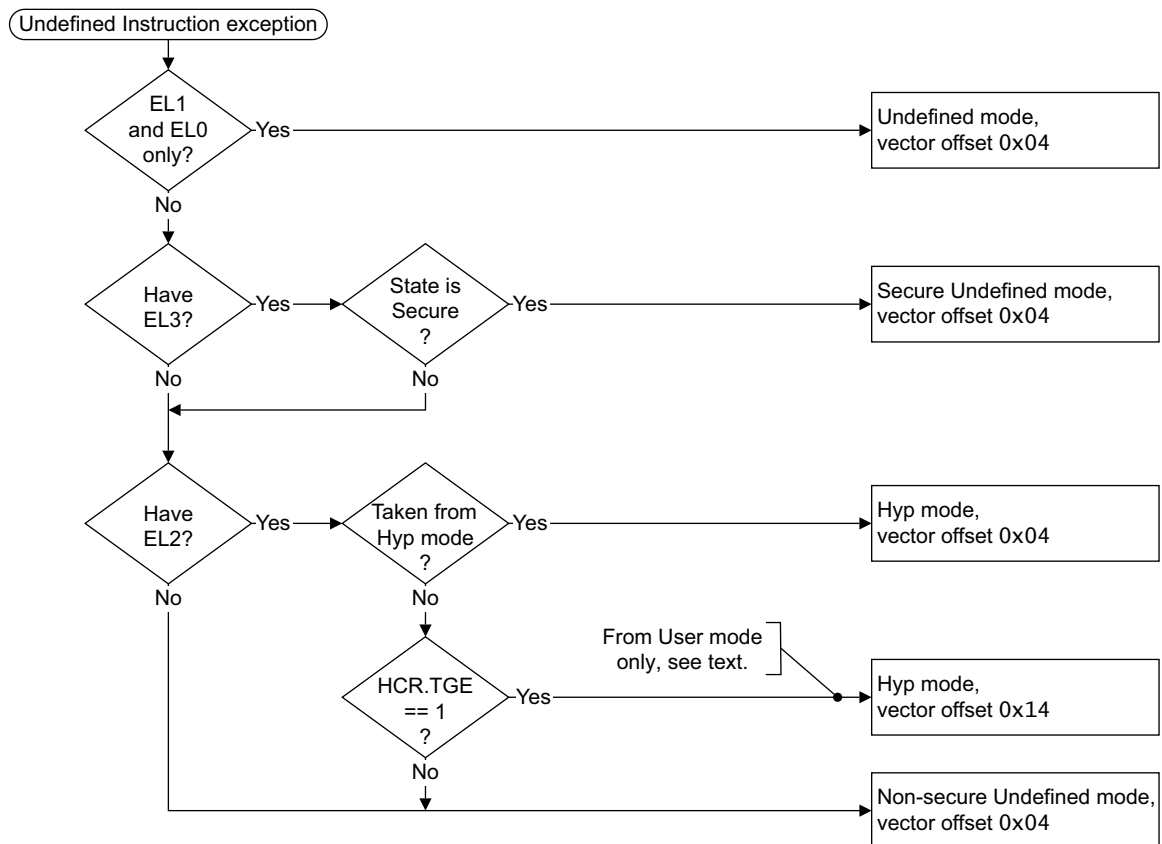

For more information, see [Exception return to an Exception level using AArch32](#) on page G1-4360.

#### ———— Note ————

If handling the Undefined Instruction exception requires instruction emulation, followed by return to the next instruction after the instruction that caused the exception, the instruction emulator must use the instruction length to calculate the correct return address, and to calculate the updated values of the IT bits if necessary.

### The PE mode to which the Undefined Instruction exception is taken

[Figure G1-4](#) shows how the implementation, state, and configuration options determine the PE mode to which an Undefined Instruction exception is taken, when the exception is taken to an Exception level that is using AArch32.

**Figure G1-4 The PE mode an Undefined Instruction exception is taken to in AArch32 state**

See also [UNPREDICTABLE cases when the value of HCR.TGE is 1](#) on page G1-4354.

## Pseudocode description of taking the Undefined Instruction exception

The `AArch32.UndefinedFault()` pseudocode procedure determines whether the Undefined Instruction exception is taken to AArch32 state. If it is taken to AArch32 state, the `AArch32.TakeUndefInstrException()` pseudocode procedure describes how the PE takes the exception.

An Undefined Instruction exception is taken to an Exception level using AArch64 if either:

- It is generated in User mode when EL1 is using AArch64.
- It is generated in Non-secure User mode when EL2 is using AArch64 and the value of `HCR_EL2.TGE` is 1.

## Conditional execution of undefined instructions

The conditional execution rules described in [Conditional execution on page F2-2849](#) apply to all instructions. This includes undefined instructions and other instructions that would cause entry to the Undefined Instruction exception.

If such an instruction fails its condition check, the behavior depends on the potential cause of entry to the Undefined Instruction exception, as follows:

- If the potential cause is the execution of the instruction itself and depends on data values used by the instruction, the instruction executes as a NOP and does not cause an Undefined Instruction exception.
- In the following cases, it is IMPLEMENTATION DEFINED whether the instruction executes as a NOP or causes an Undefined Instruction exception:
  - The potential cause is the execution of an earlier System register access instruction, floating-point instruction, or Advanced SIMD instruction.
  - The potential cause is the execution of the instruction itself without dependence on the data values used by the instruction.

An implementation must handle all such cases in the same way.

### ———— Note ————

Before ARMv7, all implementations executed any instruction that failed its condition check as a NOP, even if it would otherwise have caused an Undefined Instruction exception. An Undefined Instruction handler written for these implementations might assume without checking that the undefined instruction passed its condition check. Such an Undefined Instruction handler is likely to need rewriting, to check the condition is passed, before it functions correctly on all AArch32 implementations.

## Interaction of UNDEFINED instruction behavior with UNPREDICTABLE or CONSTRAINED UNPREDICTABLE instruction behavior

If this manual describes an instruction as both:

- UNPREDICTABLE and UNDEFINED then the instruction is UNPREDICTABLE.
- CONSTRAINED UNPREDICTABLE and UNDEFINED then the instruction is CONSTRAINED UNPREDICTABLE.

### ———— Note ————

An example of this is where both:

- An instruction, or instruction class, is made UNDEFINED by some general principle, or by a configuration field.
- A particular encoding of that instruction or instruction class is specified as CONSTRAINED UNPREDICTABLE.

### G1.15.2 Monitor Trap exception

The Monitor Trap exception is implemented only as part of EL3, and can be generated only if EL3 is using AArch32.

---

**Note**

The Monitor Trap exception is taken using offset 0x04 in the Monitor vector table. In the other vector tables, this offset is used for the Undefined Instruction exception. See [Undefined Instruction exception on page G1-4376](#) and [The vector tables and exception offsets on page G1-4341](#).

---

A Monitor Trap exception is generated if the PE is running in a mode other than Monitor mode, and commits for execution a WFI or WFE instruction that would otherwise cause suspension of execution when:

- In the case of the WFI instruction, the value of the [SCR.TWI](#) bit is 1.
- In the case of the WFE instruction, the value of the [SCR.TWE](#) bit is 1.

---

**Note**

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

The preferred return address for a Monitor Trap exception is the address of the instruction that generated the exception. The exception return uses the [SPSR](#) and [LR\\_mon](#) values generated by the exception entry, as follows:

- If [SPSR.T](#) is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
- If [SPSR.T](#) is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.

For more information, see [Exception return to an Exception level using AArch32 on page G1-4360](#).

#### The PE mode to which the Monitor Trap exception is taken

When EL3 is using AArch32, a Monitor Trap exception is taken to Monitor mode, using a vector offset of 0x04 from the Monitor exception base address.

#### Pseudocode description of taking the Monitor Trap exception

The [AArch32.TakeMonitorTrapException\(\)](#) pseudocode procedure describes how the PE takes the exception.

### G1.15.3 Hyp Trap exception

The Hyp Trap exception provides the standard mechanism for trapping Guest OS functions to the hypervisor.

The Hyp Trap exception is implemented only as part of EL2 and can be generated only if EL2 is using AArch32.

A Hyp Trap exception is generated if the PE is running in a Non-secure mode other than Hyp mode, and commits for execution an instruction that is trapped to Hyp mode. Instruction traps are enabled by setting bits to 1 in the [HCR](#), [HCPTR](#), [HDCR](#), or [HSTR](#). For more information see [EL2 configurable controls on page G1-4427](#).

Traps to Hyp mode never apply in Secure state, regardless of the value of the [SCR.NS](#) bit.

The preferred return address for a Hyp Trap exception is the address of the trapped instruction. The exception return is performed by an ERET instruction, using the [SPSR](#) and [ELR\\_hyp](#) values generated by the exception entry.

---

**Note**

The [SPSR](#) and [ELR\\_hyp](#) values generated on exception entry can be used, without modification, for an exception return to re-execute the trapped instruction. If the exception handler emulates the trapped instruction, and must return to the following instruction, the emulation of the instruction must include modifying [ELR\\_hyp](#), and possibly updating [SPSR\\_hyp](#).

---

When the PE enters the handler for a Hyp Trap exception, the [HSR](#) holds syndrome information for the exception. For more information see [Use of the HSR on page G4-4677](#).

### The PE mode to which the Hyp Trap exception is taken

A Hyp Trap exception is taken to Hyp mode, using a vector offset of 0x14 from the Hyp exception base address.

### Pseudocode description of taking the Hyp Trap exception

The [AArch32.TakeHypTrapException\(\)](#) pseudocode procedure describes how the PE takes the exception.

## G1.15.4 Supervisor Call (SVC) exception

The Supervisor Call instruction, SVC, requests a supervisor function, typically to request an operating system function. When EL1 is using AArch32, executing an SVC instruction causes the PE to enter Supervisor mode. For more information, see [SVC on page F5-3575](#).

---

**Note**

In an implementation that includes EL2, when EL2 is using AArch32:

- When an SVC instruction is executed in Hyp mode, the Supervisor Call exception is taken to Hyp mode. For more information see [SVC on page F5-3575](#).
- When the [HCR.TGE](#) bit is set to 1, the Supervisor Call exception generated by execution of an SVC instruction in Non-secure User mode is routed to Hyp mode. For more information, see [Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-4357](#).

---

By default, a Supervisor Call exception that is taken to AArch32 state is taken to Supervisor mode, but a Supervisor Call exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see [The PE mode to which the Supervisor Call exception is taken on page G1-4381](#).

The preferred return address for a Supervisor Call exception is the address of the next instruction after the SVC instruction. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from Secure or Non-secure Supervisor mode, the exception return uses the [SPSR](#) and [LR\\_svc](#) values generated by the exception entry, in an exception return instruction without subtraction.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the [SPSR](#) and [ELR\\_hyp](#) values generated by the exception entry.

For more information, see [Exception return to an Exception level using AArch32 on page G1-4360](#).

## The PE mode to which the Supervisor Call exception is taken

Figure G1-5 shows how the implementation, state, and configuration options determine the PE mode to which a Supervisor Call exception is taken, when the exception is taken to an Exception level that is using AArch32.

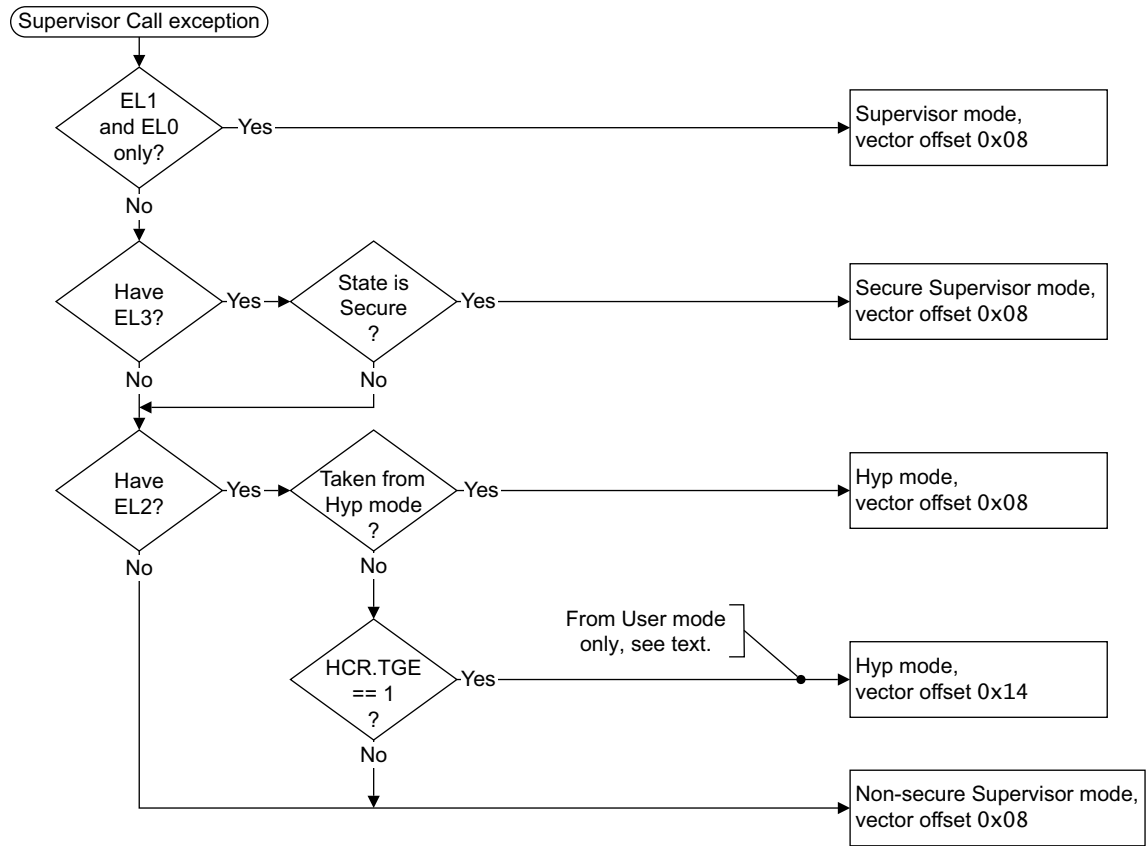

Figure G1-5 The PE mode the Supervisor Call exception is taken to in AArch32 state

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-4354.

## Pseudocode description of taking the Supervisor Call exception

The `AArch32.CallSupervisor()` pseudocode procedure determines whether the Supervisor Call exception is taken to AArch32 state. If it is taken to AArch32 state, the `AArch32.TakeSVCException()` pseudocode procedure describes how the PE takes the exception.

An Supervisor Call exception is taken to an Exception level using AArch64 if either:

- It is generated by executing an SVC instruction in User mode when EL1 is using AArch64.
- It is generated by executing an SVC instruction in Non-secure User mode when EL2 is using AArch64 and the value of `HCR_EL2.TGE` is 1.

## G1.15.5 Secure Monitor Call (SMC) exception

The Secure Monitor Call exception is implemented only as part of EL3. When EL3 is using AArch32, the exception is taken to Monitor mode.

The Secure Monitor Call instruction, SMC, requests a Secure Monitor function. When EL3 is using AArch32, executing an SMC instruction causes the PE to enter Monitor mode. For more information, see [SMC on page F5-3429](#).

---

### Note

- In an implementation that includes EL2, execution of an SMC instruction in a Non-secure EL1 mode can be trapped to EL2. When EL2 is using AArch32, this means that when [HCR.TSC 1](#), execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap Exception that is taken to Hyp mode. For more information see [Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-4434](#).
- The Operation pseudocode in the description of the AArch32 SMC instruction, in [SMC on page F5-3429](#), identifies cases where execution of the instruction generates an exception that is taken to EL3 using AArch64.

---

The preferred return address for a Secure Monitor Call exception is the address of the next instruction after the SMC instruction. For an exception taken to AArch32 state, this return is performed using the [SPSR](#) and [LR\\_mon](#) values generated by the exception entry, using an exception return instruction without a subtraction.

For more information, see [Exception return to an Exception level using AArch32 on page G1-4360](#).

---

### Note

For an exception taken to AArch32 state, the exception handler can return to the SMC instruction itself by returning using a subtraction of 4, without any adjustment to the [SPSR.IT\[7:0\]](#) bits. If it does this, the return occurs, then asynchronous exceptions might occur and be handled, then the SMC instruction is re-executed and another Secure Monitor Call exception occurs.

This relies on:

- The SMC instruction being used correctly, either outside an IT block or as the last instruction in an IT block, so that the [SPSR.IT\[7:0\]](#) bits indicate unconditional execution.
- The Secure Monitor Call handler not changing the result of the original conditional execution test for the SMC instruction.

---

## The PE mode to which the Secure Monitor Call exception is taken

The Secure Monitor Call exception is supported only as part of EL3. When EL3 is using AArch32, a Secure Monitor Call exception is taken to Monitor mode, using vector offset [0x08](#) from the Monitor exception base address.

---

### Note

- An SMC instruction that is trapped to Hyp mode because [HCR.TSC](#) is set to 1 generates a Hyp Trap exception, see [The PE mode to which the Hyp Trap exception is taken on page G1-4380](#).
- If EL3 is using AArch64 then [Security behavior in Exception levels using AArch32 when EL3 is using AArch64 on page G1-4352](#) describes the effect of executing an SMC instruction at an Exception level that is using EL1.

---

## Pseudocode description of taking the Secure Monitor Call exception

The [AArch32.TakeSMCException\(\)](#) pseudocode procedure describes how the PE takes the exception when the exception is taken to an Exception level that is using AArch32.

## G1.15.6 Hypervisor Call (HVC) exception

The Hypervisor Call exception is implemented only as part of EL2.

The Hypervisor Call instruction, HVC, requests a hypervisor function. When EL2 is using AArch32, executing an HVC instruction generates a Hypervisor Call exception that is taken to Hyp mode. For more information, see [HVC on page F5-3123](#).

### Note

- Execution of HVC instructions is disabled when the value of `SCR.HCE` is 0. Descriptions of HVC instruction execution elsewhere in this section assume the *Effective value* of `SCR.HCE` is 1.
- When EL2 is using AArch64 an HVC instruction executed in a Non-secure EL1 mode generates an exception that is taken to EL2 using AArch64. [Exception classes and the ESR\\_ELx syndrome registers on page D1-1801](#) describes how this exception is reported in `ESR_EL2`.

The preferred return address for a Hypervisor Call exception is the address of the next instruction after the HVC instruction. The exception return is performed by an ERET instruction, using the `SPSR` and `ELR_hyp` values generated by the exception entry.

For more information, see [Exception return to an Exception level using AArch32 on page G1-4360](#).

When EL2 is using AArch32, executing an HVC instruction transfers the immediate argument of the instruction to the `HSR`. The exception handler retrieves the argument from the `HSR`, and therefore does not have to access the original HVC instruction. For more information see [Use of the HSR on page G4-4677](#).

### The PE mode to which the Hypervisor Call exception is taken

The Hypervisor Call exception is supported only as part of EL2. When EL2 is using AArch32, a Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as [Figure G1-6](#) shows. This offset is from the Hyp exception base address.

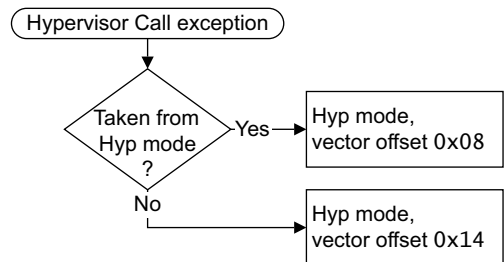

Figure G1-6 The PE mode the Hypervisor Call exception is taken to in AArch32 state

### Pseudocode description of taking the Hypervisor Call exception

The `AArch32.CallHypervisor()` pseudocode procedure determines whether the valid execution of an HVC instruction in AArch32 state generates an exception that is taken to EL2 using AArch64, or generates a Hypervisor Call exception taken to Hyp mode. The `AArch32.TakeHVCException()` pseudocode procedure describes how the PE takes a Hypervisor Call exception.

## G1.15.7 Prefetch Abort exception

A Prefetch Abort exception can be generated by:

- A synchronous memory abort on an instruction fetch.

———— **Note** ————

Asynchronous external aborts on instruction fetches are reported as SError interrupts using the Data Abort exception, see [Data Abort exception on page G1-4387](#).

A Prefetch Abort exception entry is synchronous to the instruction whose fetch aborted.

For more information about memory aborts see [VMSAv8-32 memory aborts on page G4-4649](#).

- A Breakpoint, Vector Catch or Breakpoint Instruction exception, see [Chapter G2 AArch32 Self-hosted Debug](#).

———— **Note** ————

If an implementation fetches instructions speculatively, it must handle a synchronous abort on such an instruction fetch by:

- Generating a Prefetch Abort exception only if the instruction would be executed in a simple sequential execution of the program.
- Ignoring the abort if the instruction would not be executed in a simple sequential execution of the program.

By default, when EL1 is using AArch32, a Prefetch Abort exception is taken to Abort mode, but a Prefetch Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the Prefetch Abort exception is taken to an Exception level that is using AArch32, see [The PE mode to which the Prefetch Abort exception is taken on page G1-4386](#).
- About cases where the Prefetch Abort generates an exception that is taken to an Exception level that is using AArch64, see [Pseudocode description of taking the Prefetch Abort exception on page G1-4387](#).

The preferred return address for a Prefetch Abort exception is the address of the aborted instruction. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and [LR](#) values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - [SPSR\\_abt](#) and [LR\\_abt](#) if returning from Abort mode.
  - [SPSR\\_mon](#) and [LR\\_mon](#) if returning from Monitor mode.
- If returning from Hyp mode, using the [SPSR\\_hyp](#) and [ELR\\_hyp](#) values generated by the exception entry, using an ERET instruction.

For more information about the handling of Prefetch Abort exceptions in AArch32 state see [Exception return to an Exception level using AArch32 on page G1-4360](#).

## Prefetch Abort exception reporting a PC alignment fault exception

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, and:

### If the exception is taken to EL1 using AArch32 or EL3 using AArch32

- The IFSR indicates the cause of the exception:
  - If the value of [TTBCR.EAE](#) is 0, [IFSR.FS](#) takes the value 0b00001.
  - If the value of [TTBCR.EAE](#) is 1, [IFSR.STATUS](#) takes the value 0b100001.
- [IFAR](#) holds the value of the address that faulted, including the misaligned low order bit or bits.
- [R14\\_abt](#) holds the address that faulted, including the misaligned low order bit or bits, with the standard offset for a Prefetch Abort exception.

### If the exception is taken to EL2 using AArch32

- [HSR.EC](#) takes the value 0b100010.
- [HSR.IL](#) is UNKNOWN.
- [HSR.ISS](#) is RES0.
- [HIFAR](#) and [ELR\\_hyp](#) each hold the value of the address that faulted, including the misaligned low order bit or bits.

For a PC alignment fault exception taken to an Exception level that is using AArch32:

- If the exception occurred because of the CONSTRAINED UNPREDICTABLE behavior of a branch to an unaligned PC value, as described in [Branching to an unaligned PC on page K1-6098](#), then bit[0] of the faulting address is forced to zero, and therefore the misalignment is because the value of bit[1] of this address is 1.
- If the exception occurred on an exit from Debug state, as described in [Exiting Debug state on page H2-5471](#), then it is CONSTRAINED UNPREDICTABLE whether bit[0] of the faulting address is forced to zero.

## The PE mode to which the Prefetch Abort exception is taken

Figure G1-7 shows how the implementation, state, and configuration options determine the PE mode to which a Prefetch Abort exception is taken, when the exception is taken to an Exception level that is using AArch32.

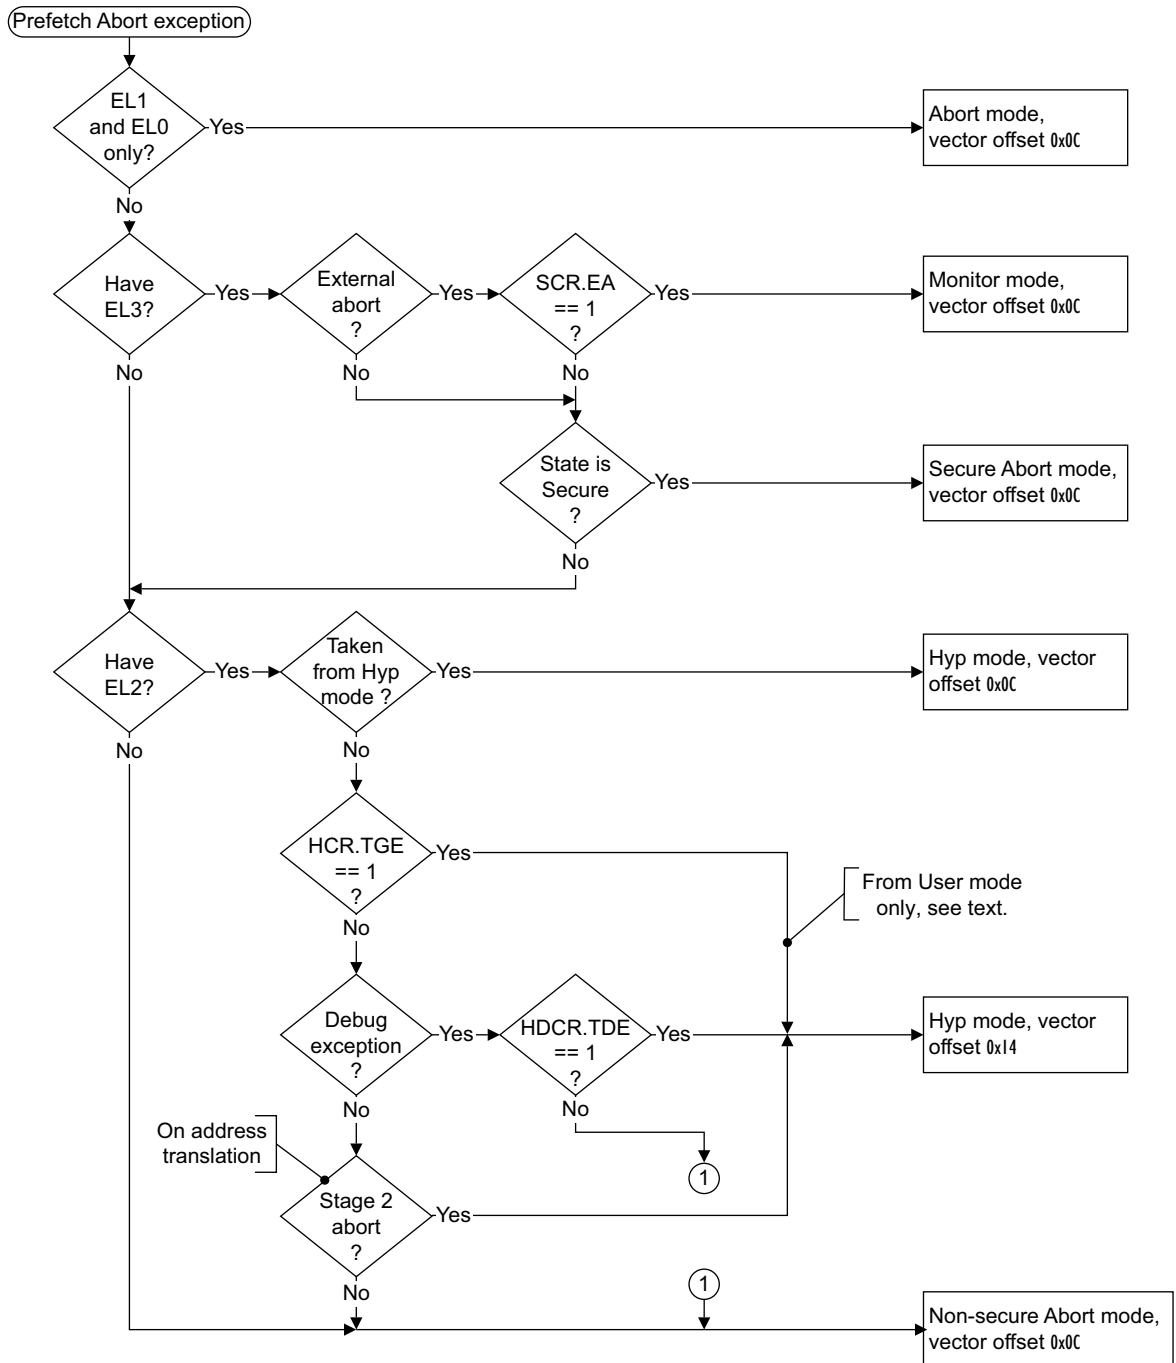

Figure G1-7 The PE mode the Prefetch Abort exception is taken to in AArch32 state

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-4354.

## Pseudocode description of taking the Prefetch Abort exception

The [AArch32.Abort\(\)](#) pseudocode function determines whether the Prefetch Abort condition generates an exception that is taken to an Exception level that is using AArch64, or generates a Prefetch Abort exception that is taken in AArch32 state. When the exception is taken in AArch32 state, the [AArch32.TakePrefetchAbortException\(\)](#) pseudocode procedure describes how the PE takes the exception.

The exception is taken to an Exception level using AArch64 if one of the following applies:

- The exception is generated in User mode when EL1 is using AArch64.
- The implementation includes EL2, EL2 is using AArch64, and one of the following applies:
  - The value of [HCR\\_EL2.TGE](#) is 1 and the exception is generated in Non-secure User mode.
  - The value of [MDCR\\_EL2.TDE](#) is 1 and the exception is generated by a Debug exception in a Non-secure EL1 or Non-secure EL0 mode.
  - The exception is generated by a stage 2 fault during a stage 1 translation table walk using the AArch32 Non-secure EL1&0 translation regime.
- The implementation includes EL3, EL3 is using AArch64, the value of [SCR\\_EL3.EA](#) is 1, and the exception is generated by an external abort in AArch32 state.

### G1.15.8 Data Abort exception

In AArch32 state, a Data Abort exception can be generated by:

- A synchronous abort on a data read or write memory access. Exception entry is synchronous to the instruction that generated the memory access.
- An SError interrupt. The SError interrupt might be caused by an external abort on a memory access, which can be any of:
  - A data read or write access.
  - An instruction fetch.
  - In a VMSA memory system, a translation table access.

Exception entry occurs asynchronously.

As described in [Asynchronous exception masking controls](#) on page G1-4368, SError interrupts can be masked. When this happens, a generated SError interrupt is not taken until it is not masked.

- A watchpoint, see [Watchpoint exceptions](#) on page G2-4496.

By default, when EL1 is using AArch32 a Data Abort exception is taken to Abort mode, but a Data Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the Data Abort exception is taken to an Exception level that is using AArch32 see [The PE mode to which the Data Abort exception is taken](#) on page G1-4389.
- About memory aborts in AArch32 state see [VMSAv8-32 memory aborts](#) on page G4-4649.
- About cases where the Data Abort generates an exception that is taken to an Exception level that is using AArch64 see [Pseudocode description of taking the Data Abort exception](#) on page G1-4390.

The preferred return address for a Data Abort exception is the address of the instruction that generated the aborting memory access, or the address of the instruction following the instruction boundary at which an SError interrupt exception was taken. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and LR values generated by the exception entry, using an exception return instruction with a subtraction of 8. This means using:
  - [SPSR\\_abt](#) and [LR\\_abt](#) if returning from Abort mode.
  - [SPSR\\_mon](#) and [LR\\_mon](#) if returning from Monitor mode.
- If returning from Hyp mode, using the [SPSR\\_hyp](#) and [ELR\\_hyp](#) values generated by the exception entry, using an ERET instruction.

For more information about the handling of Data Abort exceptions in AArch32 state see [Exception return to an Exception level using AArch32](#) on page G1-4360.

## The PE mode to which the Data Abort exception is taken

Figure G1-8 shows the determination of the mode to which a Data Abort exception is taken when the exception is taken to an Exception level that is using AArch32.

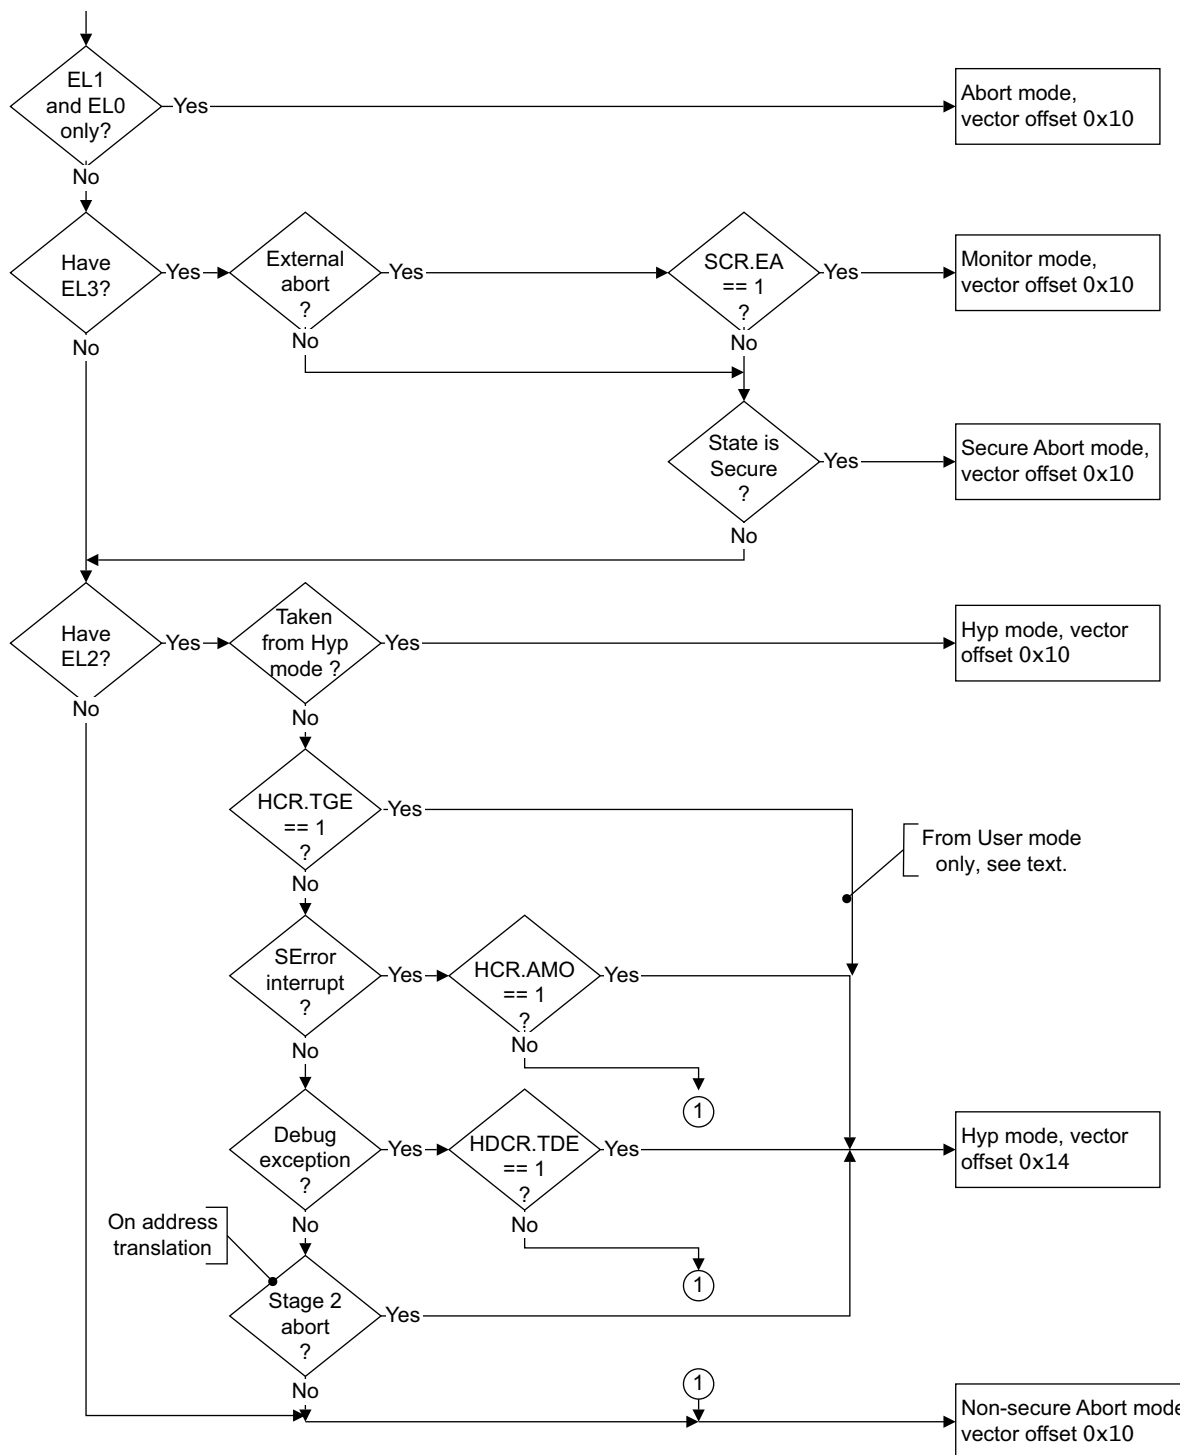

Figure G1-8 The PE mode the Data Abort exception is taken to in AArch32 state

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-4354.

## Pseudocode description of taking the Data Abort exception

The `AArch32.Abort()` pseudocode function determines whether the Data Abort condition generates an exception that is taken to an Exception level that is using AArch64, or generates a Data Abort exception that is taken in AArch32 state. When the exception is taken in AArch32 state, the `AArch32.TakeDataAbortException()` pseudocode procedure describes how the PE takes the exception.

The exception is taken to an Exception level using AArch64 if one of the following applies:

- The exception is generated in User mode when EL1 is using AArch64.
- The implementation includes EL2, EL2 is using AArch64, and one of the following applies:
  - The value of `HCR_EL2.TGE` is 1 and the exception is generated in Non-secure User mode.
  - The value of `MDCR_EL2.TDE` is 1 and the exception is generated by a Debug exception in a Non-secure EL1 or Non-secure EL0 mode.
  - The exception is generated by a stage 2 fault during a stage 1 translation table walk using the AArch32 Non-secure EL1&0 translation regime.
- The implementation includes EL3, EL3 is using AArch64, the value of `SCR_EL3.EA` is 1, and the exception is generated by an external abort in AArch32 state.

## Effects of data-aborted instructions

An instruction that accesses data memory can modify memory by storing one or more values. If the execution of such an instruction generates a Data Abort exception, or causes Debug state entry because of a watchpoint set on the instruction, the value of each memory location that the instruction stores to is:

- Unchanged for any location for which one of the following applies:
  - An MMU fault is generated.
  - A Watchpoint is generated.
  - An external abort is generated, if that external abort is taken synchronously.
- UNKNOWN for any location for which no exception and no debug event is generated.

If the access to a memory location generates an external abort that is taken asynchronously, it is outside the scope of the architecture to define the effect of the store on that memory location, because this depends on the system-specific nature of the external abort. However, in general, ARM recommends that such locations are unchanged.

For external aborts and Watchpoints, where in principle faulting could be identified at byte or halfword granularity, the size of a location in this definition is the size for which a memory access is single-copy atomic.

In AArch32 state, instructions that access data memory can modify registers in the following ways:

- By loading values into one or more of the general-purpose registers. The registers loaded can include the PC.
- By loading values into one or more of the registers in the Advanced SIMD and floating-point register file.
- By specifying *base register writeback*, in which the base register used in the address calculation has a modified value written to it. All instructions that support base register writeback have CONSTRAINED UNPREDICTABLE results if base register writeback is specified with the PC as the base register. Only general-purpose registers can be modified reliably in this way.
- By a direct or indirect write to one or more System registers, for example:
  - An LDC instruction that writes to `DBGDTRTXint` using a value read from memory is a *direct write* to the System register `DBGDTRTXint`.
  - An STC instruction that reads `DBGDTRRXint` makes an *indirect write* to `DBGDSCRint.RXfull`.
- By modifying `PSTATE`.

If the execution of such an instruction generates a synchronous Data Abort exception, the following rules determine the values left in these registers:

- On entry to the Data Abort exception handler:
  - The PC value is the Data Abort vector address, see [Exception vectors and the exception base address on page G1-4340](#).
  - The LR\_abt value is determined from the address of the aborted instruction.
 Neither value is affected by the results of any load specified by the instruction.
- The base register is restored to its original value if either:
  - The aborted instruction is a load and the list of registers to be loaded includes the base register.
  - The base register is being written back.
- If the instruction only loads one general-purpose register the value in that register is unchanged.
- If the instruction loads more than one general-purpose register, UNKNOWN values are left in destination registers other than the PC and the base register of the instruction.
- If the instruction affects any registers in the Advanced SIMD and floating-point register file, UNKNOWN values are left in the registers that are affected.
- **PSTATE** bits that are not defined as updated on exception entry retain their current value.
- If the instruction is a STREX, STREXB, STREXH, or STREXD, <Rd> is not updated.

After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN. Therefore, ARM strongly recommends that the abort handler performs a CLREX instruction, or a dummy STREX instruction, to clear the Exclusives monitor state.

### The ARM abort model

The abort model used by an ARM PE is described as a *Base Restored Abort Model*. This means that if a synchronous Data Abort exception is generated by executing an instruction that specifies base register writeback, the value in the base register is unchanged.

The abort model applies uniformly across all instructions.

## G1.15.9 Virtual SError interrupt exception

The Virtual SError interrupt exception is implemented only as part of EL2.

A Virtual SError interrupt exception is generated in AArch32 state if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of **PSTATE.A** is 0.
- Either:
  - EL2 is using AArch32 and the values of the **HCR**.{TGE, AMO, VA} bits are {0, 1, 1}.
  - EL2 is using AArch64 and the values of the **HCR\_EL2**.{TGE, AMO, VA} bits are {0, 1, 1}.

The conditions for generating a Virtual SError interrupt exception in AArch32 state mean the exception is:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure Abort mode if EL1 is using AArch32.
- Taken to Non-secure EL1 using AArch64 if Non-secure EL0 is using AArch32 and Non-secure EL1 is using AArch64.

For more information see [Virtual exceptions when an implementation includes EL2 on page G1-4365](#).

---

**Note**

---

Because a Virtual SError interrupt exception taken to AArch32 state is always taken to Non-secure Abort mode, on exception entry the preferred return address is always saved to LR\_abt.

---

The preferred return address for a Virtual SError interrupt exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state, this return is performed using the [SPSR](#) and LR\_abt values generated by the exception entry, using an exception return instruction without subtraction.

### The PE mode to which the Virtual SError interrupt exception is taken

The Virtual SError interrupt exception is supported only as part of EL2. A Virtual SError interrupt exception is taken from a Non-secure EL1 or EL0 mode, and when taken to AArch32 state is taken to Non-secure Abort mode, using a vector offset of 0x10 from the Non-secure exception base address.

For more information about this exception see [Virtual exceptions when an implementation includes EL2 on page G1-4365](#).

### Pseudocode description of taking the Virtual SError interrupt exception

The [AArch32.TakeVirtualSErrorException\(\)](#) pseudocode procedure describes how the PE takes the exception. This procedure includes the case where in Non-secure state EL0 is using AArch32 and EL1 is using AArch64, and the exception is taken to EL1 using AArch64.

---

**Note**

---

This is the only case where the exception is taken from an Exception level using AArch32 to an Exception level using AArch64.

---

## G1.15.10 IRQ exception

The IRQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an IRQ interrupt request input to the PE.

When an IRQ exception is taken, exception entry is precise to an instruction boundary.

As described in [Asynchronous exception masking controls on page G1-4368](#), IRQ exceptions can be masked. When this happens, a generated IRQ exception is not taken until it is not masked.

By default, when EL1 is using AArch32, an IRQ exception is taken to IRQ mode, but an IRQ exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the exception is taken to an Exception level using AArch32 see [The PE mode to which the physical IRQ exception is taken on page G1-4393](#).
- About cases where the exception is taken to an Exception level using AArch64 see [Pseudocode description of taking the physical IRQ exception on page G1-4394](#).

The preferred return address for an IRQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the **SPSR** and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - **SPSR\_irq** and **LR\_irq** if returning from IRQ mode.
  - **SPSR\_mon** and **LR\_mon** if returning from Monitor mode.
- If returning from Hyp mode, using the **SPSR\_hyp** and **ELR\_hyp** values generated by the exception entry, using an ERET instruction.

For more information, see [Exception return to an Exception level using AArch32](#) on page G1-4360.

### The PE mode to which the physical IRQ exception is taken

Figure G1-9 shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken when the exception is taken to an Exception level that is using AArch32.

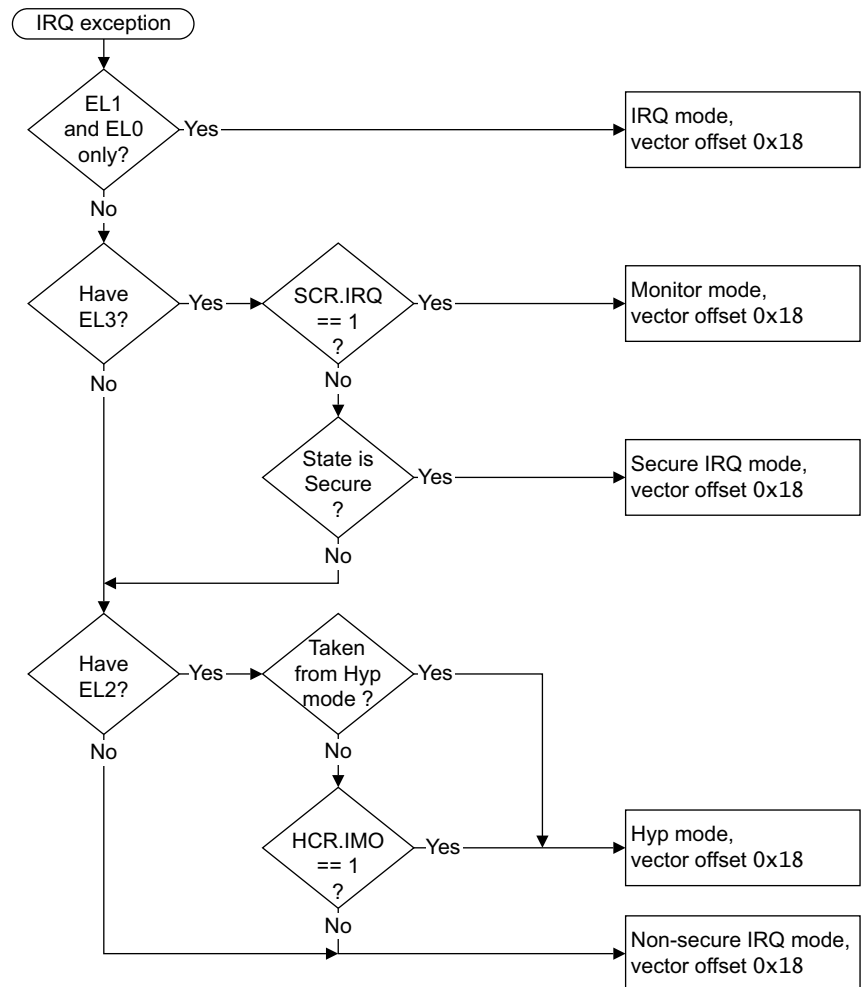

Figure G1-9 The PE mode the IRQ exception is taken to in AArch32 state

## Pseudocode description of taking the physical IRQ exception

The [AArch32.TakePhysicalIRQException\(\)](#) pseudocode procedure describes how the PE takes the exception. This procedure includes the case where the exception is taken to an Exception level that is using AArch64. This happens if one of the following applies:

- The exception is taken from User mode and EL1 is using AArch64. The Exception is taken to EL1 using AArch64.
- The exception is taken from Non-secure User mode, EL2 is implemented and using AArch64, and the value of [HCR\\_EL2.TGE](#) is 1. The Exception is taken to EL2 using AArch64, in Non-secure state.
- The exception is taken from a Non-secure EL0 or EL1 mode, EL2 is implemented and using AArch64, and the value of [HCR\\_EL2.IMO](#) is 1. The Exception is taken to EL2 using AArch64, in Non-secure state.
- The exception is taken from a PE mode other than Monitor mode, EL3 is implemented and using AArch64, and the value of [SCR\\_EL3.IRQ](#) is 1. The Exception is taken to EL3 using AArch64.

### G1.15.11 Virtual IRQ exception

The Virtual IRQ exception is implemented only as part of EL2.

A Virtual IRQ exception is generated in AArch32 state if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of [PSTATE.I](#) is 0.
- Either:
  - EL2 is using AArch32 and the value of [HCR.{TGE, IMO}](#) is {0, 1}.
  - EL2 is using AArch64 and the value of [HCR\\_EL2.{TGE, IMO}](#) is {0, 1}.
- One of the following applies:
  - EL2 is using AArch32 and the value of [HCR.VI](#) is 1.
  - EL2 is using AArch64 and the value of [HCR\\_EL2.VI](#) is 1.
  - A Virtual IRQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual IRQ exception in AArch32 state mean the exception is:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure IRQ mode if EL1 is using AArch32.
- Taken to Non-secure EL1 using AArch64 if Non-secure EL0 is using AArch32 and Non-secure EL1 is using AArch64.

For more information see [Virtual exceptions when an implementation includes EL2 on page G1-4365](#).

The preferred return address for a Virtual IRQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the [SPSR](#) and [LR\\_irq](#) values generated by the exception entry, using an exception return instruction with a subtraction of 4.

### The PE mode to which the Virtual IRQ exception is taken

The Virtual IRQ exception is supported only as part of EL2. A Virtual IRQ exception is taken from a Non-secure EL1 or EL0 mode, and when taken to AArch32 state is taken to Non-secure IRQ mode, using a vector offset of 0x18 from the Non-secure exception base address.

For more information about this exception see [Virtual exceptions when an implementation includes EL2 on page G1-4365](#).

## Pseudocode description of taking the Virtual IRQ exception

The [AArch32.TakeVirtualIRQException\(\)](#) pseudocode procedure describes how the PE takes the exception. This procedure includes the case where, in Non-secure state, EL0 is using AArch32 and EL1 is using AArch64, and the exception is taken to Non-secure EL1 using AArch64.

### ———— Note ————

This is the only case where the exception is taken from an Exception level using AArch32 to an Exception level using AArch64.

## G1.15.12 FIQ exception

The FIQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an FIQ interrupt request input to the PE.

When an FIQ exception is taken, exception entry is precise to an instruction boundary.

As described in [Asynchronous exception masking controls on page G1-4368](#), FIQ exceptions can be masked. When this happens, a generated FIQ exception is not taken until it is not masked.

By default, an FIQ exception is taken to FIQ mode, but an FIQ exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information:

- About cases where the exception is taken to an Exception level using AArch32 see [The PE mode to which the physical FIQ exception is taken on page G1-4396](#).
- About cases where the exception is taken to an Exception level using AArch64 see [Pseudocode description of taking the FIQ exception on page G1-4396](#).

The preferred return address for an FIQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - [SPSR\\_fiq](#) and [LR\\_fiq](#) if returning from FIQ mode.
  - [SPSR\\_mon](#) and [LR\\_mon](#) if returning from Monitor mode.
- If returning from Hyp mode, using the [SPSR\\_hyp](#) and [ELR\\_hyp](#) values generated by the exception entry, using an ERET instruction.

For more information see [Exception return to an Exception level using AArch32 on page G1-4360](#).

## The PE mode to which the physical FIQ exception is taken

Figure G1-9 on page G1-4393 shows how the implementation, state, and configuration options determine the PE mode to which an FIQ exception is taken when the exception is taken to an Exception level that is using AArch32.

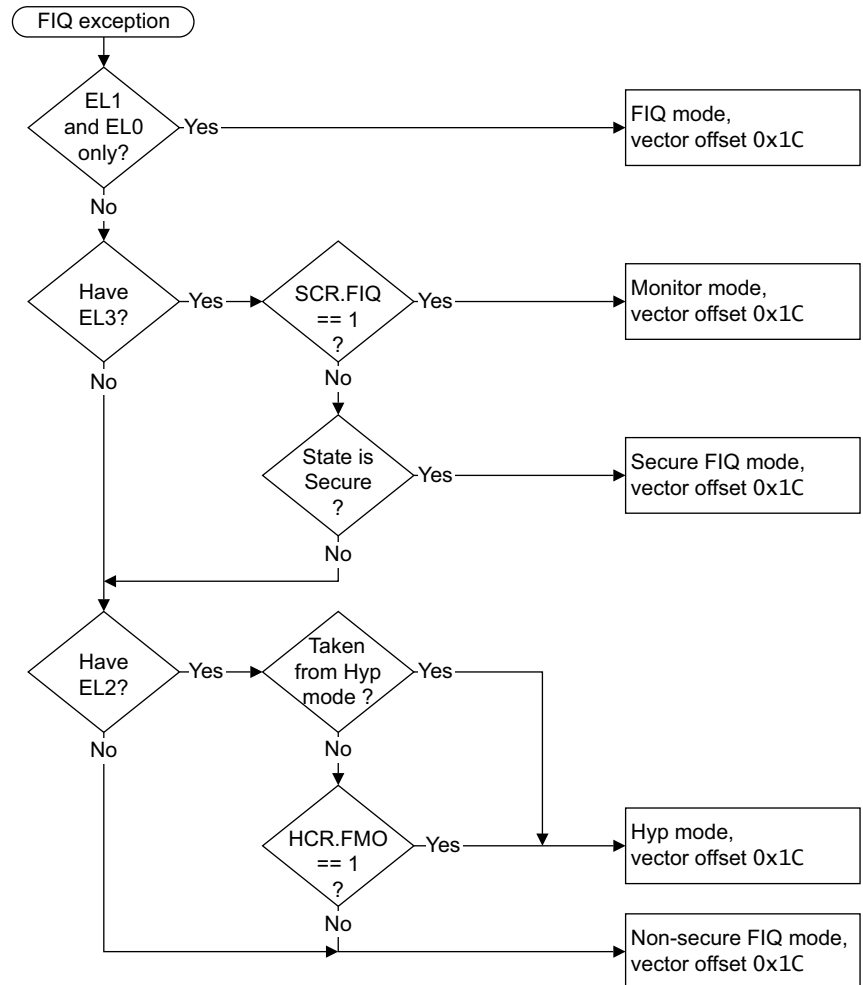

Figure G1-10 The PE mode the FIQ exception is taken to in AArch32 state

## Pseudocode description of taking the FIQ exception

The `AArch32.TakePhysicalFIQException()` pseudocode procedure describes how the PE takes the exception. This procedure includes the case where the exception is taken to an Exception level that is using AArch64. This happens if one of the following applies:

- The exception is taken from User mode and EL1 is using AArch64. The Exception is taken to EL1 using AArch64.
- The exception is taken from Non-secure User mode, EL2 is implemented and using AArch64, and the value of `HCR_EL2.TGE` is 1. The Exception is taken to EL2 using AArch64, in Non-secure state.
- The exception is taken from a Non-secure EL0 or EL1 mode, EL2 is implemented and using AArch64, and the value of `HCR_EL2.FMO` is 1. The Exception is taken to EL2 using AArch64, in Non-secure state.
- The exception is taken from a PE mode other than Monitor mode, EL3 is implemented and using AArch64, and the value of `SCR_EL3.FIQ` is 1. The Exception is taken to EL3 using AArch64.

### G1.15.13 Virtual FIQ exception

The Virtual FIQ exception is implemented only as part of EL2.

A Virtual FIQ exception is generated in AArch32 state if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of `PSTATE.F` is 0.
- Either:
  - EL2 is using AArch32 and the value of `HCR.{TGE, FMO}` is {0, 1}.
  - EL2 is using AArch64 and the value of `HCR_EL2.{TGE, FMO}` is {0, 1}.
- One of the following applies:
  - EL2 is using AArch32 and the value of `HCR.VF` is 1.
  - EL2 is using AArch64 and the value of `HCR_EL2.VF` is 1.
  - A Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual FIQ exception in AArch32 state mean the exception is:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure FIQ mode if EL1 is using AArch32.
- Taken to Non-secure EL1 using AArch64 if Non-secure EL0 is using AArch32 and Non-secure EL1 is using AArch64.

For more information see [Virtual exceptions when an implementation includes EL2 on page G1-4365](#).

The preferred return address for a Virtual FIQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the `SPSR` and `LR_irq` values generated by the exception entry, using an exception return instruction with a subtraction of 4.

#### The PE mode to which the Virtual FIQ exception is taken

The Virtual FIQ exception is supported only as part of EL2. A Virtual FIQ exception is taken from a Non-secure EL1 or EL0 mode, and when taken to AArch32 state is taken to Non-secure FIQ mode, using a vector offset of `0x1C` from the Non-secure exception base address.

For more information about this exception see [Virtual exceptions when an implementation includes EL2 on page G1-4365](#).

#### Pseudocode description of taking the Virtual FIQ exception

The `AArch32.TakeVirtualFIQException()` pseudocode procedure describes how the PE takes the exception. This procedure includes the case where, in Non-secure state, EL0 is using AArch32 and EL1 is using AArch64, and the exception is taken to Non-secure EL1 using AArch64.

#### ———— Note —————

This is the only case where the exception is taken from an Exception level using AArch32 to an Exception level using AArch64.

#### G1.15.14 Additional pseudocode functions for exception handling

The [AArch32.EnterMonitorMode\(\)](#) pseudocode function changes the PE mode to Monitor mode, with the required state changes.

The [AArch32.EnterHypMode\(\)](#) pseudocode function changes the PE mode to Hyp mode, with the required state changes.

The [AArch32.EnterMode\(\)](#) pseudocode function changes the PE mode to a PL1 mode, with the required state changes. It is used for all exceptions that are not routed to Hyp mode or Monitor mode.

The [AArch32.EnterMonitorMode\(\)](#), [AArch32.EnterHypMode\(\)](#), and [AArch32.EnterMode\(\)](#) functions are described in [Chapter J1 ARMv8 Pseudocode](#).

## G1.16 Reset into AArch32 state

[Reset on page D1-1795](#) describes the ARMv8 reset model, including the defined levels of reset. When reset is deasserted, the PE starts executing instructions in the highest implemented Exception level. If that Exception level is using AArch32, then it starts execution:

- In Secure state, if the implementation includes EL3.
- With interrupts disabled:
  - In Hyp mode, if the highest implemented Exception level is EL2.
  - In Supervisor mode, otherwise.

---

### Note

- This section describes the architectural requirements for a reset into AArch32 state. It takes no account of whether ARM licenses any particular combination of Exception levels and Execution state. For more information about the licensed combinations see [Support for Exception levels and Execution states on page D1-1900](#).
  - The Execution state in which the highest implemented Execution level starts executing instructions on coming out of reset might be determined by a configuration input signal.
- 

Reset returns some PE state to architecturally-defined or IMPLEMENTATION DEFINED values, and makes other state UNKNOWN, as described in [PE state on reset into AArch32 state on page G1-4400](#). For more information about behavior when resetting into an Exception level using AArch32, see:

- [Behavior of caches at reset on page G3-4531](#).
- [Enabling stages of address translation on page G4-4569](#).
- [TLB behavior at reset on page G4-4629](#).
- [Reset and debug on page H6-5545](#).

When reset is deasserted, if the PE resets into an Exception level that is using AArch32, it is IMPLEMENTATION DEFINED whether execution starts:

- From an IMPLEMENTATION DEFINED address.
- If reset is into EL3 or EL1, from the low or high reset vector address, as determined by the reset value of the [SCTLR.V](#) bit. This reset value can be determined by an IMPLEMENTATION DEFINED configuration input signal.

---

### Note

This option might be implemented for compatibility with earlier versions of the architecture.

---

Software might be able to identify the reset address:

- If reset is into EL3, by reading the reset value of [MVBAR](#). That is, after coming out of reset, by reading [MVBAR](#) before the boot software has updated it. It is IMPLEMENTATION DEFINED whether this discovery mechanism is supported.
- If reset is into EL2 or EL1, by reading [RVBAR](#). [RVBAR](#) can only be implemented at the highest implemented Exception level, and only if that Exception level is not EL3.

If [RVBAR](#) is not implemented, and at all Exception levels other than the highest implemented Exception level, the encoding for [RVBAR](#) is UNDEFINED.

The ARM architecture does not define any way of returning to a previous Execution state from a reset.

## G1.16.1 PE state on reset into AArch32 state

---

### Note

---

See the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* for the reset requirements for GIC System registers.

---

Immediately after a reset, much of the PE state is UNKNOWN. However, some of the PE state is defined. If the PE resets to AArch32 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- If reset is into EL3 using AArch32 then all fields of the **SCR** reset to zero.

---

### Note

---

This means **SCR.NS** correctly indicates that the PE is in Secure state.

---

- If reset is into EL2 using AArch32 then reset is into Hyp mode and **CPSR.M** resets to 0b1010, otherwise reset is into Supervisor mode and **CPSR.M** resets to 0b0011,
- **CPSR.IL** resets to 0.
- The **CPACR**.{cp11, cp10} fields reset to zero, and if **CPACR.ASEDIS** is implemented as an RW field it resets to zero.

---

### Note

---

When **CPACR.TRCDIS** is a RW field, its reset value is architecturally UNKNOWN.

---

- **PSTATE** is reset to the values defined by the **AArch32.TakeReset()** pseudocode function, see *Pseudocode descriptions of reset on page G1-4402*.
- The **FPEXC.EN** field resets to 0.
- In the **SCTLR**:
  - The {AFE, TRE, UWXN, WXN, I, SED, ITD, C, A, M} fields reset to 0.
  - The {nTWE, nTWI, CP15BEN} fields reset to 1.
  - The {TE, EE, V} fields reset to IMPLEMENTATION DEFINED values, see the register description for more information.

When the reset is to EL3 using AArch32 then these reset values apply only to the Secure instance of the **SCTLR**, and the reset value of the Non-secure **SCTLR** is architecturally UNKNOWN.

- All field of the **TTBCR** reset to 0.  
When the reset is to EL3 using AArch32 then:
  - All fields of the Secure **TTBCR** reset to 0.
  - In the Non-secure **TTBCR**, the EAE field resets to 0, and the reset values of all other fields are architecturally UNKNOWN.
- The **VBAR** resets to an IMPLEMENTATION DEFINED value.  
When the reset is to EL3 using AArch32 then this reset value applies only to the Secure instance of the register, and the reset value of the Non-secure **VBAR** is architecturally UNKNOWN.
- All fields of the **DBGDCCINT** reset to 0.
- The **DBGDSCRext**.{MDBGen, UDCCdis} fields reset to 0.
- The **DBGOSDLR**.DLK field resets to 0.

In addition:

**If the reset is into EL1 using AArch32**

- In the [RMR](#) register, the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a cold reset.

**If the reset is into EL2 using AArch32**

- In the [HRMR](#), the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a cold reset.
- The [HSCTLR](#).{I, C, M} fields all reset to 0, and the [HSCTLR](#).EE field resets to an IMPLEMENTATION DEFINED value.

**If the reset is into EL2 using AArch32 or into EL3 using AArch32**

For a reset into EL3 using AArch32 these reset values apply only if the implementation includes EL2, see the register descriptions for more information.

- All fields of the [HCPTR](#) reset to zero.
- All fields of the [HCR](#) reset to zero.
- The [HCR2](#).{ID, CD} fields reset to zero.
- All fields of the [HSTR](#) reset to zero.
- The [VMPIDR](#) resets to the value of the [MPIDR](#), see the register description for more information.
- The [VPIDR](#) resets to the value of the [MIDR](#), see the register description for more information.
- The [VTTBR](#).VMID field resets to zero.
- In the [HDCR](#):
  - The HPMN field resets to the IMPLEMENTATION DEFINED value of [PMCR](#).N.
  - The reset value of the HPME field is architecturally UNKNOWN.
  - All other fields reset to 0.

**If the reset is into EL3 using AArch32**

- The [MVBAR](#) resets to an IMPLEMENTATION DEFINED value, see the register description for more information.
- If the [NSACR](#).{NSTRCDIS, NSASEDIS} fields are RW fields then they reset to 0.
- In the [RMR](#) register, the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a cold reset.
- All fields of the [SCR](#) reset to zero.
- All fields of the [SDER](#) reset to 0.
- All fields of the [SDCR](#) reset to zero.

**For either a warm or a cold reset**

- The [EDPRSR](#).SR field resets to 1.
- The [EDES](#).{SS, RC, OSUC} fields reset to 0.

**For a cold reset only**

- The [EDSCR](#).{RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull} fields reset to 0.
- The [EDECCR](#).{NSE, SE} fields reset to 0.
- The [EDPRSR](#).{SPMAD, SDAD} fields reset to 0, and the [EDPRSR](#).SPD field resets to 1.
- The [DBGOSLSR](#).OSLK field resets to 1.
- The [DBGPRCR](#).CORENPDRQ field resets to the value of [EDPRCR](#).COREPURQ.

An External Debug reset sets [EDPRCR.COREPURQ](#) to 0, see [External debug register resets on page H8-5572](#). If an External Debug reset and a cold reset coincide, both [DBGPRCR.CORENPRDRQ](#) and [EDPRCR.COREPURQ](#) are reset to 0.

- The debug CLAIM bits are reset to 0.

---

**Note**

These are the bits that are set to 1 by writing to [DBGCLAIMSET.CLAIM](#), and reset to 0 by writing to [DBGCLAIMCLR.CLAIM](#).

---

## G1.16.2 Pseudocode descriptions of reset

The [AArch32.TakeReset\(\)](#) pseudocode procedure describes how the PE behaves when reset is deasserted.

The [AArch32.ResetGeneralRegisters\(\)](#) pseudocode function resets the general-purpose registers.

The [AArch32.ResetSIMDFPRegisters\(\)](#) pseudocode function resets the SIMD and floating-point registers.

The [AArch32.ResetSpecialRegisters\(\)](#) pseudocode function resets the Special-purpose registers, and the debug System registers [DLR](#) and [DSPSR](#), that are used for handling Debug exceptions.

The [AArch32.ResetSystemRegisters\(\)](#) pseudocode function resets all System registers in the (coproc==0b111x) encoding space to their reset state as defined in the register descriptions in [Chapter G6 AArch32 System Register Descriptions](#).

---

**Note**

The [ResetSystemRegisters\(\)](#) function only resets the System registers. It has no effect on memory-mapped registers.

---

The [ResetExternalDebugRegisters\(\)](#) pseudocode function resets all external debug registers to their reset state as defined in the register descriptions in [Chapter H9 External Debug Register Descriptions](#).

## G1.17 Mechanisms for entering a low-power state

The following sections describe the architectural mechanisms that a PE can use to request entry to a low-power state:

- [Wait For Event and Send Event](#).
- [Wait For Interrupt](#) on page G1-4406.

### G1.17.1 Wait For Event and Send Event

The Wait For Event (WFE) mechanism permits a PE to request entry to a low-power state, and, if the request succeeds, to remain in that state until an event is generated by a Send Event operation, or another WFE wake-up event occurs. [Example G1-2](#) describes how a spinlock implementation might use this mechanism to save energy.

#### Example G1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device it might need to add data received from the device to a queue. If another PE is removing data from the queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the lock has been released. It cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in [Synchronization and semaphores](#) on page E2-2795.
- If the PE obtains the lock it performs its memory operation and releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. At this point it again attempts to obtain the lock.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multithreaded implementation the execution of spin-locks by waiting threads can significantly degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock. In this situation, a PE that fails to obtain a lock can execute a Wait For Event instruction, WFE, to request entry to a low-power state. When a PE releases a lock, it must execute a Send Event instruction, SEV, causing any waiting PEs to wake up. Then, these PEs can attempt to gain the lock again.

The execution of a WFE instruction can cause suspension of execution only if all of the following are true:

- The instruction does not cause any other exception.
- When the instruction is executed:
  - The Event Register is not set.
  - There is not a pending WFE wakeup event.

For more information about the trap to EL2 see [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions](#) on page G1-4437.

The architecture does not define the exact nature of the low power state entered as a result of executing a WFE instruction, but the execution of a WFE instruction must not cause a loss of memory coherency.

---

### Note

---

Although a complex operating system can contain thousands of distinct locks, the event sent by this mechanism does not indicate which lock has been released. If the event relates to a different lock, or if another PE acquires the lock more quickly, the PE fails to acquire the lock and can reenter the low-power state waiting for the next event.

---

The Wait For Event system relies on hardware and software working together to achieve energy saving:

- The hardware provides the mechanism to enter the Wait For Event low-power state.
- The operating system software is responsible for issuing:
  - A Wait For Event instruction, to request entry to the low-power state, used in the example when waiting for a spin-lock.
  - A Send Event instruction, required in the example when releasing a spin-lock.

The mechanism depends on the interaction of:

- WFE wake-up events, see [WFE wake-up events on page G1-4405](#).
- The Event Register, see [The Event Register](#).
- The Send Event instructions, see [The Send Event instructions on page G1-4405](#).
- The Wait For Event instruction, see [The Wait For Event instruction](#).

## The Event Register

The Event Register is a single bit register for each PE. When set, an event register indicates that an event has occurred, since the register was last cleared, that might require some action by the PE. Therefore, the PE must not suspend operation on issuing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- The execution of an SEVL instruction by the PE.
- An exception return.
- An event from a Generic Timer event stream, see [Event streams on page G5-4757](#).
- An event sent by some IMPLEMENTATION DEFINED mechanism.

As shown in this list, the Event Register might be set by IMPLEMENTATION DEFINED mechanisms.

The Event Register is cleared only by a Wait For Event instruction.

Software cannot read or write the value of the Event Register directly.

## The Wait For Event instruction

The action of the Wait For Event instruction depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately. Normally, if this happens the software makes another attempt to claim the lock.
- If the Event Register is clear the PE can suspend execution, and hardware might enter a low-power state. The PE can remain suspended until a WFE wake-up event or a reset occurs. When a WFE wake-up event occurs, or earlier if the implementation chooses, the WFE instruction completes.

The execution in AArch32 state of a WFE instruction that would otherwise cause suspension of execution might be trapped, see:

- [Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-4421](#).
- [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437](#).
- [Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-4447](#).

The Wait For Event instruction, WFE, is available at all privilege levels, see [WFE on page F5-3668](#).

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake ups.

## WFE wake-up events

The following events are *WFE wake-up events*:

- The execution of an SEV instruction on any PE in the system.
- The execution of an SEVL instruction on the PE.
- A physical IRQ interrupt, unless masked by the [PSTATE.I](#) bit.
- A physical FIQ interrupt, unless masked by the [PSTATE.F](#) bit.
- A physical SError interrupt, unless masked by the [PSTATE.A](#) bit.
- In Non-secure state in any mode other than Hyp mode:
  - When [HCR.IMO](#) is set to 1, a virtual IRQ interrupt, unless masked by the [PSTATE.I](#) bit.
  - When [HCR.FMO](#) is set to 1, a virtual FIQ interrupt, unless masked by the [PSTATE.F](#) bit.
  - When [HCR.AMO](#) is set to 1, a virtual SError interrupt, unless masked by the [PSTATE.A](#) bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed* see [Halting allowed and halting prohibited on page H2-5435](#).  
See also [External Debug Request debug event on page H3-5490](#).
- An event sent by the timer event stream, see [Event streams on page D6-2186](#).
- An event sent by some IMPLEMENTATION DEFINED mechanism.
- An event caused by the clearing of the global monitor associated with the PE.

In addition to the possible masking of WFE wake-up events shown in this list, when invasive debug is enabled and [EDSCR.HDE](#) is set to 1, [EDSCR.INTdis](#) can mask interrupts, including masking them acting as WFE wake-up events. For more information, see [EDSCR, External Debug Status and Control Register on page H9-5662](#).

As shown in the list of wake-up events, an implementation can include IMPLEMENTATION DEFINED hardware mechanisms to generate wake-up events.

---

### Note

For more information about [PSTATE](#) masking see [Asynchronous exception masking controls on page G1-4368](#). If the configuration of the masking controls provided by EL2 and EL3 mean that a [PSTATE](#) mask bit cannot mask the corresponding exception, then the physical exception is a WFE wake-up event, regardless of the value of the [PSTATE](#) mask bit.

---

## The Send Event instructions

The Send Event instructions are:

**SEV, Send Event** This causes an event to be signaled to all PEs in the multiprocessor system.

**SEVL, Send Event Local**

This must set the local Event Register. It might signal an event to other PEs, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before any SEV instruction.

---

### Note

A DSB instruction ensures that no instruction, including any SEV instruction, that appears in program order after the DSB instruction, can execute until the DSB instruction has completed. For more information, see [Data Synchronization Barrier \(DSB\) on page E2-2769](#).

---

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

Execution of the Send Event instruction sets the Event Register.

The Send Event instructions are available at all privilege levels.

### Pseudocode description of the Wait For Event mechanism

This section defines pseudocode functions that describe the operation of the Wait For Event mechanism.

The [ClearEventRegister\(\)](#) pseudocode procedure clears the Event Register of the current PE.

The [IsEventRegisterSet\(\)](#) pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The [WaitForEvent\(\)](#) pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a [ClearEventRegister\(\)](#) to occur.

The [SendEvent\(\)](#) pseudocode procedure sets the Event Register of every PE in the system.

## G1.17.2 Wait For Interrupt

AArch32 state supports Wait For Interrupt through an instruction, WFI, that is provided in the A32 and T32 instruction sets. For more information, see [WFI on page F5-3670](#).

When a PE issues a WFI instruction, its execution can be suspended, and a low-power state can be entered.

The execution in AArch32 state of a WFI instruction that would otherwise cause suspension of execution might be trapped, see:

- [Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-4421](#).
- [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437](#).
- [Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-4447](#).

The execution of a WFI instruction can cause suspension of execution only if both:

- The instruction does not cause any other exception.
- When the instruction is executed, there is not a pending WFI wakeup event.

### WFI wake-up events

The PE can remain suspended in its WFI state until it is reset, or one of the following *WFI wake-up events* occurs:

- A physical IRQ interrupt, regardless of the value of the [PSTATE.I](#) bit.
- A physical FIQ interrupt, regardless of the value of the [PSTATE.F](#) bit.
- A physical SError interrupt, regardless of the value of the [PSTATE.A](#) bit.
- In Non-secure state in any mode other than Hyp mode:
  - When [HCR.IMO](#) is set to 1, a virtual IRQ interrupt, regardless of the value of the [PSTATE.I](#) bit.
  - When [HCR.FMO](#) is set to 1, a virtual FIQ interrupt, regardless of the value of the [PSTATE.F](#) bit.
  - When [HCR.AMO](#) is set to 1, a virtual SError interrupt, regardless of the value of the [PSTATE.A](#) bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed* see [Halting allowed and halting prohibited on page H2-5435](#).

See also [External Debug Request debug event on page H3-5490](#).

An implementation can include other IMPLEMENTATION DEFINED hardware mechanisms to generate WFI wake-up events.

When a WFI wake-up event is detected, or earlier if the implementation chooses, the WFI instruction completes.

WFI wake-up events cannot be masked by the mask bits in the [PSTATE](#).

The architecture does not define the exact nature of the low power state, but the execution of a WFI instruction must not cause a loss of memory coherency.

---

**Note**

- Because debug events are WFI wake-up events, ARM strongly recommends that is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures the intervention of debug while waiting does not significantly change the function of the program being debugged.
- In some previous implementations of Wait For Interrupt, the idle loop is followed by exit functions that must be executed before taking the interrupt. The operation of Wait For Interrupt remains consistent with this model, and therefore differs from the operation of Wait For Event.
- Some implementations of Wait For Interrupt drain down any pending memory activity before suspending execution. The ARM architecture does not require this operation, and software must not rely on Wait For Interrupt operating in this way.

---

## Using WFI to indicate an idle state on bus interfaces

A common implementation practice is to complete any entry into powerdown routines with a WFI instruction. Typically, the WFI instruction:

1. Forces the completion of execution of any instructions that are in progress, and of all associated bus activity.
2. Suspends the execution of instructions by the PE.

The control logic required to do this tracks the activity of the bus interfaces used by the PE. This means it can signal to an external power controller when there is no ongoing bus activity.

However, memory-mapped and external debug interface accesses to debug registers must continue to be processed while the PE is in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the value of `DBGOSDLR.DLK`, the OS Double Lock status bit, is set to 1, this idle state must not be signaled to the PE unless the system can guarantee, also, that the debug interface is idle.

---

**Note**

When separate core and debug power domains are implemented, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see [Power domains and debug on page H6-5535](#).

---

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

## Pseudocode description of Wait For Interrupt

The `WaitForInterrupt()` pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.

## G1.18 The AArch32 System register interface

In ARMv8, most system registers are accessed using the instructions described in [System register access instructions on page F1-2828](#). The System register interface provides access to those instructions, and:

- These registers are encoded using the parameters {coproc, opc1, CRn, CRm, opc2}, with permitted coproc values of 0b1110 and 0b1111.
- Some of these encodings provide the AArch32 System instructions summarized in:
  - [Cache maintenance instructions, functional group on page G4-4734](#).
  - [TLB maintenance instructions, functional group on page G4-4735](#).
  - [Address translation instructions, functional group on page G4-4737](#).
- To maintain compatibility with previous versions of the ARM architecture, the access controls for the AArch32 System registers include the access controls for AArch32 Advanced SIMD and floating-point functionality.

———— **Note** ————

See [Background to the System register interface on page G1-4410](#) for more information.

The following sections give more information about the AArch32 System register interface:

- [System registers in the coproc == 0b111x encoding space](#).
- [Access to System registers](#).
- [Access controls for Advanced SIMD and floating-point functionality on page G1-4409](#).
- [Pseudocode description of checking accesses to the System registers on page G1-4409](#).
- [Background to the System register interface on page G1-4410](#).

### G1.18.1 System registers in the coproc == 0b111x encoding space

In AArch32 state:

- The coproc == 0b1110 encoding space is reserved for the configuration and control of:
  - Debug features, see [Debug registers on page G6-5239](#).
  - Trace features, see the *Embedded Trace Macrocell Architecture Specification*.
  - Identification registers for the Trivial Jazelle implementation, see [Trivial implementation of the Jazelle extension on page G1-4338](#).
- The coproc == 0b1111 encoding space is reserved for the control and configuration of the PE, including architecture and feature identification. This means these encodings provide access to the System registers that control and return status information for PE operation.

For more information see [Chapter G6 AArch32 System Register Descriptions](#).

### G1.18.2 Access to System registers

Most System registers are accessible only from EL1 or higher. For possible accesses from EL0:

- The register descriptions in [Chapter G6 AArch32 System Register Descriptions](#) indicate whether a register is accessible from EL0.
- [PL0 views of the System registers in the \(coproc==0b1111\) encoding space on page G4-4723](#) summarizes the permitted accesses to System registers in the coproc == 0b1111 encoding space from EL0.

### G1.18.3 Access controls for Advanced SIMD and floating-point functionality

In ARMv8, the [CPACR](#) controls access to Advanced SIMD and floating-point functionality from software executing at PL1 or EL0 in AArch32 state:

- The {cp10, cp11} fields control access to all Advanced SIMD and floating-point functionality, and can:
  - Disable EL0 and PL1 access to this functionality.
  - Enable access to this functionality at PL1 only.
  - Enable access to this functionality at EL0 and PL1.
- The [ASEDIS](#) field controls access to Advanced SIMD instructions that are not also floating-point instructions.

Initially on powerup or reset into AArch32 state, all access to all Advanced SIMD and floating-point functionality from PL1 and EL0 is disabled.

#### ———— **Note** ————

The [CPACR](#) has no effect on accesses from Hyp mode.

If an implementation includes EL3, the [NSACR](#) determines whether Advanced SIMD and floating-point functionality can be accessed from Non-secure state:

- The {cp10, cp11} fields control Non-secure access to all Advanced SIMD and floating-point functionality.
- The [NSASEDIS](#) field controls Non-secure access to Advanced SIMD instructions that are not also floating-point instructions.

If an implementation includes EL2, the [HCPTR](#) provides additional controls on Non-secure accesses to Advanced SIMD and floating-point functionality. For accesses that are otherwise permitted by the [CPACR](#) and [NSACR](#) settings, setting [HCPTR](#) bits to 1:

- Traps otherwise-permitted accesses from EL1 or EL0 to EL2. When EL2 is using AArch32, these accesses are trapped to Hyp mode.
- Makes accesses from EL2 mode UNDEFINED. When EL2 is using AArch32, this makes accesses from Hyp mode UNDEFINED.

In the [HCPTR](#):

- The {TCP10, TCP11} fields control access to all Advanced SIMD and floating-point functionality.
- The [TASE](#) field controls access to Advanced SIMD instructions that are not also floating-point instructions.
- The [TCPAC](#) field traps Non-secure EL1 accesses to the [CPACR](#) to Hyp mode.

For more information, see [General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers](#) on page G1-4437.

#### ———— **Note** ————

Whenever a pair of fields control the access to the Advanced SIMD and floating-point functionality, the values of each field of the pair must be identical. In ARMv8, if these settings are not identical the behavior of the Advanced SIMD and floating-point functionality is CONSTRAINED UNPREDICTABLE, see [Handling of System register control fields for Advanced SIMD and floating-point operation](#) on page K1-6102.

For more information about Advanced SIMD and floating-point support see [Advanced SIMD and floating-point support](#) on page G1-4412.

### G1.18.4 Pseudocode description of checking accesses to the System registers

The [AArch32.CheckSystemAccess\(\)](#) function determines whether a System register access instruction that targets a System register in the (coproc == 0b111x) encoding space is accepted.

## G1.18.5 Background to the System register interface

### Note

This section is not part of the ARMv8 Architecture specification. It is included only to present the rationale of some aspects of the System register interface.

The interface to the System registers was originally defined as part of a generic *coprocessor* interface, that gave access to fifteen coprocessors, CP0 - CP15. Of these, CP8 - CP15 were reserved for use by ARM, while CP0 - CP7 were available for IMPLEMENTATION DEFINED coprocessors.

The coprocessors were accessed using coprocessor instructions. These instructions remain part of the T32 and A32 instruction sets, see [System register access instructions on page F1-2828](#).

In the ARM coprocessor model, a coprocessor included both:

- Primary and secondary coprocessor registers, that form part of the coprocessor interface.
- A number of internal registers.

When accessing a 32-bit internal coprocessor register, using an MCR or MRC instruction, the instruction specified:

- The target coprocessor, specified by the coproc parameter and taking a value between p0 for CP0 and p15 for CP15.
- The primary coprocessor register, specified by the CRn parameter and taking a value between c0 and c15.
- The secondary coprocessor register, specified by the CRm parameter and taking a value between c0 and c15.
- Up to two additional parameters, opc1 and opc2, taking values between 0 and 7.

Other instructions in the group described in [System register access instructions on page F1-2828](#) take a subset of these parameters:

- In the ARMv7 definitions, LDC and STC instructions take parameters {coproc, CRd}, where CRd is the primary coprocessor register.
- MCRR and MRRC instructions take parameters {coproc, opc1, CRm}, where CRm is the primary coprocessor register.

To maintain backwards compatibility, the arguments to an MCR or MRC instruction remain {coproc, opc1, CRn, CRm, opc2}. Correspondingly, the encoding of the AArch64 System registers is described using the parameters {op0, op1, CRn, CRm, op2}. However:

- The naming of these parameters no longer has any particular significance.
- While the coproc field is a 4-bit field, op0 is a 2-bit field.

Of the coprocessors reserved for use by ARM, in ARMv7 and earlier versions of the architecture:

- CP15 provided access to the System registers relating to non-debug operation, and was originally called the System control coprocessor. In ARMv8 these registers are described as being in the coproc == 0b1111 encoding space.
- CP14 provided access to additional System registers, including those relating to debug and trace. In ARMv8 these registers are described as being in the coproc == 0b1110 encoding space.
- CP10 and CP11 were used for Advanced SIMD and floating-point control, and many coprocessor instruction encodings targeting CP10 and CP11 were used as floating-point instruction encodings:
  - Generally ARMv8 does not relate these instructions to the coprocessor encoding space, but the naming of registers and register fields for Advanced SIMD and floating-point control reflects the historic coprocessor model.
  - Because the Advanced SIMD and floating-point functionality used both CP10 and CP11, some System register controls of this functionality have a pair of fields, for example NSACR.{cp10, cp11}. In these cases, both fields must be set to the same value. For more information see [Access controls for Advanced SIMD and floating-point functionality on page G1-4409](#).

In ARMv8:

- The AArch32 System registers include registers that were described as Special registers in ARMv7 and earlier versions of the architecture. This means that the ARMv8 System registers include registers that are outside the earlier coprocessor model.
- The ARMv7 AArch32 instruction encodings for LDC, STC, MCR, MRC, MCRR, and MRRC instructions with coproc field values other than {1010, 1011, 1110, 1111} are available for reuse. **ARMv8.2 re-uses some encodings in this way.**

## G1.19 Advanced SIMD and floating-point support

[Advanced SIMD and floating-point instructions on page E1-2740](#) introduces:

- The scalar floating-point instructions in the A32 and T32 instruction sets.
- The Advanced SIMD integer and floating-point vector instructions in the A32 and T32 instruction sets.
- The SIMD and floating-point register file, that can be viewed as:
  - Singleword registers S0 - S31.
  - Doubleword registers D0 - D31.
  - Quadword registers Q0 - Q15.
- The *Floating-Point Status and Control Register (FPSCR)*.

For more information about the System registers for the Advanced SIMD and floating-point operation see [Advanced SIMD and floating-point System registers on page G1-4415](#). Software can interrogate these registers to discover the implemented Advanced SIMD and floating-point support.

[AArch32 implications of not including support for Advanced SIMD and floating-point](#) summarizes the effects of not supporting these instructions, and the following subsections give more information about the Advanced SIMD and Floating-point support:

- [Enabling Advanced SIMD and floating-point support on page G1-4413](#).
- [Advanced SIMD and floating-point System registers on page G1-4415](#).
- [Context switching when using Advanced SIMD and floating-point functionality on page G1-4415](#).
- [Floating-point exception traps on page G1-4416](#).

### G1.19.1 AArch32 implications of not including support for Advanced SIMD and floating-point

As stated in [Implementations not including Advanced SIMD and floating-point instructions on page D1-1901](#), although ARMv8-A generally requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets, for implementations targeting specialized markets, ARM might produce or license ARMv8-A implementations that do not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- The **CPACR**.{ASEDIS, cp11, cp10} fields are RES0.
- The **NSACR**.{NSASEDIS, cp11, cp10} fields are RES0.
- The **HCPtr**.{TASE, TCP11, TCP10} fields are RES1.
- The **FPEXC**, **FPSCR**, **FPSID**, **MVFR0**, **MVFR1**, and **MVFR2** registers are not implemented and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
  - All Advanced SIMD and floating-point instructions are UNDEFINED.
  - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.

## G1.19.2 Enabling Advanced SIMD and floating-point support

Software must ensure that the required access to the Advanced SIMD and floating-point features is enabled. Most of those controls are described in [Configurable instruction enables and disables, and trap controls on page G1-4418](#), and this section:

- Summarizes those controls.
- Provides additional information in the following subsections:
  - [FPExc control of access to Advanced SIMD and floating-point functionality on page G1-4414](#).
  - [EL0 access to Advanced SIMD and floating-point functionality on page G1-4414](#).

### ———— Note ————

This section shows the controls when the controlling Exception levels are using AArch32. Similar controls are provided when the Exception levels are using AArch64, and then apply to lower Exception levels that are using AArch32.

The controls of access to Advanced SIMD and floating-point functionality are:

#### General {cp10, cp11} or {TCP10, TCP11} controls

This relates to the [CPACR](#).{cp10, cp11}, [NSACR](#).{cp10, cp11}, and [HCPTR](#).{TCP10, TCP11} controls.

### ———— Note ————

[Background to the System register interface on page G1-4410](#) explains the naming of these controls.

The {cp10, cp11} controls provide general control of the use of Advanced SIMD and floating-point functionality, as follows:

- [CPACR](#).{cp10, cp11} control access from PE modes other than Hyp mode.  
These fields have no effect on accesses to Advanced SIMD and floating-point functionality from Hyp mode.
- In an implementation that includes EL3, [NSACR](#).{cp10, cp11} control access from Non-secure state.
- In an implementation that includes EL2, if [NSACR](#).{cp10, cp11} permit Non-secure accesses, or if EL3 is not implemented, [HCPTR](#).{TCP10, TCP11} provide an additional control on those accesses.

In each case, the {cp10, cp11} controls must be programmed to the same value, otherwise operation is CONSTRAINED UNPREDICTABLE. The ARMv8 CONSTRAINED UNPREDICTABLE behavior is that, for all purposes other than reading the value of the register field, behavior is as if the cp11 field has the same value as the cp10 field. For more information see [Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-6102](#).

For more information about these controls, see:

- [Enabling PL0 and PL1 accesses to the SIMD and floating-point registers on page G1-4423](#).
- [General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-4437](#).
- [Enabling Non-secure access to SIMD and floating-point functionality on page G1-4449](#).

#### Control of accesses to the CPACR from Non-secure PL1 modes

As stated in [General {cp10, cp11} or {TCP10, TCP11} controls](#), the [CPACR](#) controls access to Advanced SIMD and floating-point functionality from PE modes other than Hyp mode. Accesses to the [CPACR](#) from Non-secure PL1 modes can be trapped to EL2, see [Traps to Hyp mode of Non-secure EL1 accesses to the CPACR on page G1-4439](#).

#### Additional controls of Advanced SIMD functionality

- If implemented as an RW field, [CPACR](#).ASEDIS can make all Advanced SIMD instructions UNDEFINED in all modes other than Hyp mode.

- In an implementation that includes EL3, when [CPACR.ASEDIS](#) permits use of the Advanced SIMD instructions or if the [CPACR.ASEDIS](#) control is not implemented, [NSACR.NSASEDIS](#) can make all Advanced SIMD instructions UNDEFINED in Non-secure state.
- In an implementation that includes EL2, when the [CPACR](#) and [NSACR](#) settings permit Non-secure use of the Advanced SIMD instructions, if [HCPTR.TASE](#) is implemented as an RW field it can make these instructions UNDEFINED in Hyp mode, and trap to Hyp mode any use of these instructions in a Non-secure PL0 or PL1 mode.

For more information about these controls, see:

- [Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-4424.](#)
- [Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-4438.](#)
- [Disabling Non-secure access to Advanced SIMD functionality on page G1-4450.](#)

[Pseudocode description of enabling SIMD and floating-point functionality on page G1-4451](#) provides links to the pseudocode descriptions of all of these controls.

### FPEXC control of access to Advanced SIMD and floating-point functionality

In addition, [FPEXC.EN](#) is an enable bit for most Advanced SIMD and floating-point operations. When [FPEXC.EN](#) is 0, all Advanced SIMD and floating-point instructions are treated as UNDEFINED except for:

- A VMSR to the [FPEXC](#) or [FPSID](#) register.
- A VMRS from the [FPEXC](#), [FPSID](#), [MVFR0](#), [MVFR1](#), or [MVFR2](#) register.

These instructions can be executed only at EL1 or higher.

#### ———— Note ————

- When the [FPSID](#) is accessible, any write access to the [FPSID](#) is ignored.
- When [FPEXC.EN](#) is 0, these operations are treated as UNDEFINED:
  - A VMSR to the [FPSCR](#).
  - A VMRS from the [FPSCR](#).

See [Enabling access to the SIMD and floating-point registers on page G1-4424](#) for more information about the scope of the [FPEXC.EN](#) control.

When executing at EL0, the PE behaves as if the value of [FPEXC.EN](#) is 1 if either:

- EL1 is using AArch64.
- Execution is in Non-secure state, EL2 is using AArch64. and the value of [HCR\\_EL2.TGE](#) is 1.

#### ———— Note ————

In this state, if the value of [HCR\\_EL2.RW](#) is 0 then it is permitted for the value of [FPEXC32\\_EL2.EN](#) to control whether Advanced SIMD and floating-point functionality is enabled. However, ARM deprecates using the value of [FPEXC32\\_EL2.EN](#) to determine behavior.

### EL0 access to Advanced SIMD and floating-point functionality

When the access controls summarized in this section permit EL0 access to the Advanced SIMD and floating-point functionality, this applies only to the subset of functionality that is available at EL0. In particular:

- Only Advanced SIMD and Floating-point System register that is accessible is the [FPSCR](#).
- The Advanced SIMD and floating-point instructions are available.

Execution at EL0 corresponds to the application level view of the Advanced SIMD and floating-point functionality, as described in [Advanced SIMD and floating-point System registers on page E1-2742](#).

### G1.19.3 Advanced SIMD and floating-point System registers

AArch32 state provides a common set of System registers for the Advanced SIMD and floating-point functionality. This section gives general information about this set of registers, and indicates where each register is described in detail. It contains the following subsections:

- [Register map of the Advanced SIMD and floating-point System registers.](#)
- [Accessing the Advanced SIMD and floating-point System registers.](#)

#### Register map of the Advanced SIMD and floating-point System registers

Table G4-66 on page G4-4745 shows the register map of the Advanced SIMD and Floating-point registers. Each register is 32 bits wide. In an implementation that includes EL3, the Advanced SIMD and Floating-point registers are common registers, see [Common System registers on page G4-4698](#).

#### Accessing the Advanced SIMD and floating-point System registers

Software accesses the Advanced SIMD and floating-point System registers using the VMRS and VMSR instructions, see:

- [VMRS on page F6-4017.](#)
- [VMSR on page F6-4020.](#)

For example:

```
VMRS <Rt>, FPSID    ; Read Floating-Point System ID Register
VMRS <Rt>, MVFR1     ; Read Media and VFP Feature Register 1
VMSR FPSCR, <Rt>    ; Write Floating-Point System Control Register
```

Software can access the Advanced SIMD and floating-point System registers only if the access controls permit the access, see [Enabling Advanced SIMD and floating-point support on page G1-4413](#).

#### ———— Note ————

All hardware ID information can be accessed only from EL1 or higher. This means:

##### The FPSID is accessible only from EL1 or higher.

This is a change introduced from VFPv3. Previously, the FPSID register can be accessed in all modes.

##### The MVFR registers are accessible only from EL1 or higher.

Unprivileged software must issue a system call to determine what features are supported.

### G1.19.4 Context switching when using Advanced SIMD and floating-point functionality

When the Advanced SIMD and floating-point functionality is used by only a subset of processes, the operating system might implement lazy context switching of the Advanced SIMD and floating-point register file and System registers.

In the simplest lazy context switch implementation, the primary context switch software uses the CPACR.{cp10, cp11} controls to disable access to the Advanced SIMD and floating-point functionality, see [Enabling Advanced SIMD and floating-point support on page G1-4413](#). Subsequently, when a process or thread attempts to use an Advanced SIMD or floating-point instruction, it triggers an Undefined Instruction exception. The operating system responds by saving and restoring the Advanced SIMD and floating-point register file and System registers. Typically, it then re-executes the Advanced SIMD or floating-point instruction that generated the Undefined Instruction exception.

## G1.19.5 Floating-point exception traps

Execution of a floating-point instruction can generate an exceptional condition, called a *floating-point exception*.

The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

---

### Note

Do not confuse floating-point exceptions with the AArch32 architectural exceptions summarized in [AArch32 state exception descriptions on page G1-4376](#).

---

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:

- For an implementation that does provide this capability, **FPSCR**.{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the floating-point exceptions.
- For an implementation that does provide this capability, the **FPSCR**.{IDE, IXE, UFE, OFE, DZE, IOE} are RAZ/WI.

---

### Note

The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

---

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level. This means that trapped floating-point exceptions taken:

- From EL0 are taken to EL1, except for the following cases when they are taken from Non-secure EL0 to EL2:
  - EL2 is using AArch32 and the value of **HCR**.TGE is 1.
  - EL2 is using AArch64 and the value of **HCR\_EL2**.TGE is 1
- From EL1 are taken to EL1.
- From EL2 are taken to EL2.
- From EL3 are taken to EL3.

If the exception is taken to an Exception level that is using AArch64 then it is reported in the **ELR\_ELx** for the Exception level to which it is taken, as described in [Exception entry on page D1-1799](#).

If the exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception, see [Undefined Instruction exception on page G1-4376](#). The **FPEXC** identifies the floating-point exceptions that occurred since the corresponding status bits in that register were last set to 0.

See also [Floating-point exceptions and exception traps on page E1-2743](#).

In an implementation that provides synchronous exception generation for floating-point exceptions:

- Synchronous exception generation applies to floating-point exceptions generated by scalar SIMD and floating-point instructions executed in AArch32 state.
- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception flags in the event of such an exception.

ARMv8 does not support the trapping of floating-point exceptions from Advanced SIMD instructions executed in AArch32 state,

The [AArch32.FPTrappedException\(\)](#) and [FPPProcessException\(\)](#) pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch32 state.

The [AArch32.FPTrappedException\(\)](#) and [FPPProcessException\(\)](#) functions are described in [Chapter J1 ARMv8 Pseudocode](#).

## G1.20 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch32 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an *instruction enable*, an *instruction disable*, or a *trap control*:

### Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Privilege level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

The exception generated by attempting to executed an UNDEFINED instruction is:

- Taken to EL1 if the UNDEFINED instruction was executed at EL0, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356](#).

When the exception is taken to EL1 it is taken to Undefined mode.

- Otherwise, taken to the Exception level at which the UNDEFINED instruction was executed:
  - If the instruction was executed in Hyp mode the exception is taken to Hyp mode.
  - Otherwise, the exception is taken to Undefined mode.

### Trap controls

Control whether one or more instructions, when executed at a particular Privilege level, are *trapped*.

#### ———— Note ————

AArch32 trap controls are described in terms of Privilege levels, rather than Exception levels, because the PL1 traps apply at and are controlled from:

**EL1** In Non-secure state, and in Secure state when EL3 is using AArch64.

**EL3** In Secure state when EL3 is using AArch32.

For more information see [Security state, Exception levels, and AArch32 execution privilege on page G1-4318](#).

Trap controls are grouped as:

#### PL1, excluding Monitor mode

Trapped instructions generate Undefined Instruction exceptions that are taken to Undefined mode, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356](#).

For more information about these traps see [PL1 configurable controls on page G1-4419](#).

#### Hyp mode (PL2)

These traps apply only to execution in Non-secure state. This section only describes the traps that apply when EL2 is using AArch32.

Trapped instructions generate:

- Hyp Trap exceptions, taken to Hyp mode, if trapped from a mode other than Hyp mode.
- Undefined Instruction exceptions taken to Hyp mode, if trapped from Hyp mode.

For more information about these traps see [EL2 configurable controls on page G1-4427](#).

See also [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356](#).

#### Monitor mode (Secure PL1)

This section only describes the traps that apply when EL3 is using AArch32.

Trapped instructions generate Monitor Trap exceptions, that are taken to Monitor mode.

For more information about these traps see [EL3 configurable controls on page G1-4446](#).

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if the instruction does not also generate a higher priority exception. [Exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) defines the prioritization of different exceptions on the same instruction.

Exceptions generated as a result of these controls are synchronous exceptions.

For exceptions taken to an Exception level that is using AArch32, only exceptions that are taken to Hyp mode are reported in a syndrome register, the [HSR](#).

---

**Note**

- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, [CPACR](#).TRCDIS is a trap control even though TRCDIS is a mnemonic for Trace Disable.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.
- [Configurable instruction enables and disables, and trap controls on page D1-1842](#) describes controls provided by AArch64 state for enabling, disabling, and trapping instructions. Generally, where an AArch64 control applies to execution at lower Exception levels, it traps the equivalent functionality when that lower Exception level is using AArch32. See the AArch64 trap controls for more information.

---

This section is organized as follows:

- [Register access instructions](#).
- [PL1 configurable controls](#).
- [EL2 configurable controls on page G1-4427](#).
- [EL3 configurable controls on page G1-4446](#).
- [Pseudocode description of configurable instruction enables, disables, and traps on page G1-4451](#).

## **G1.20.1 Register access instructions**

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:

- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

## **G1.20.2 PL1 configurable controls**

In AArch32 state, each control is associated with a particular System register field that is accessible:

- When EL3 is using AArch64, or when an implementation does not include EL3, from EL1.
- When EL3 is using AArch32:
  - In Non-secure state, from EL1.
  - In Secure state, from EL3.

This means that the controls are described as PL1 controls, because PL1 is defined as being the Privilege level of software that is executing:

- At EL3, if the PE is executing in EL3 and EL3 is using AArch32.
- At EL1 under all other conditions.

Where there is an AArch64 control that is equivalent to an AArch32 PL1 control, the AArch64 control is an EL1 control.

Any exception that is generated because of an AArch32 PL1 control is taken to a PL1 mode.

---

**Note**

Any exception generated because of an AArch32 PL1 control is taken to AArch32 state.

---

Table G1-25 shows the AArch32 System registers that contain these controls.

**Table G1-25 System registers that contain instruction enables and disables, and trap controls**

Register name	Register description
SCTLR	System Control Register
FPEXC	Floating-point Exception Control Register
CPACR	Architectural Feature Access Control Register
DBGDSCRext	Monitor System Debug Control Register
PMUSERENR	Performance Monitors User Enable Register

Table G1-26 summarizes these controls.

**Table G1-26 Instruction enables and disables, and trap controls, for exceptions taken to Undefined mode**

Control	Control type <sup>a</sup>	Description
SCTLR.{nTWE, nTWI}	T	Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-4421
SCTLR.{SED, ITD}	D	Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality on page G1-4421
SCTLR.CP15BEN	E	
CPACR.TRCDIS	T	Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers on page G1-4422
CPACR.{cp11, cp10}	E	Enabling use of Advanced SIMD and floating-point functionality on page G1-4423

CNTKCTL.{PL0PTEN, PL0VTEN, PL0PCTEN, PL0VCTEN}	T	Traps to Undefined mode of EL0 accesses to the Generic Timer registers on page G1-4425
PMUSERENR.{ER, CR, SW, EN}	T	Traps to Undefined mode of EL0 accesses to Performance Monitors registers on page G1-4425

a. See Table G1-27.

**Table G1-27 Control types, for exceptions taken to Undefined mode**

Abbreviation	Type	See
D	Disable	Instruction enables and instruction disables on page G1-4418
E	Enable	Instruction enables and instruction disables on page G1-4418
T	Trap	Trap controls on page G1-4418

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-4356.

## Instructions that fail their Condition code check

See [Conditional execution of undefined instructions on page G1-4378](#).

## Trapping to PL1 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates an Undefined Instruction exception.

## Traps to Undefined mode of EL0 execution of WFE and WFI instructions

**SCTLR**.{nTWE, nTWI} trap EL0 execution of WFE and WFI instructions to Undefined mode:

### **SCTLR**.nTWE

- |          |   |
|----------|---|
| <b>1</b> | This control has no effect on the EL0 execution of WFE instructions.  |
| <b>0</b> | Any attempt to execute a WFE instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state. |

### **SCTLR**.nTWI

- |          |   |
|----------|---|
| <b>1</b> | This control has no effect on the EL0 execution of WFI instructions.  |
| <b>0</b> | Any attempt to execute a WFI instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state. |

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

### ———— **Note** ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356](#).

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait For Event and Send Event on page G1-4403](#).
- [Wait For Interrupt on page G1-4406](#).

## Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality

[Table G1-28 on page G1-4422](#) shows the deprecated AArch32 functionality that might have disable controls in the **SCTLR**:

- The SED control is always implemented.
- Whether each of the ITD or CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

When an instruction is disabled by one of these controls, it is UNDEFINED at PL0 and PL1. This means an attempt to execute the instruction at PL0 or PL1 generates an Undefined Instruction exception that is taken to Undefined mode, unless both of the following apply, in which case the attempted execution generates an exception that is taken to EL2, as described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356](#):

- The instruction is executed at Non-secure EL0 using AArch32.
- Either:
  - EL2 is using AArch32 and the value of **HCR**.TGE is 1.
  - EL2 is using AArch64 and the value of **HCR**\_**EL2**.TGE is 1.

**Table G1-28 PL1 controls for disabling and enabling PL0 and PL1 use of AArch32 deprecated functionality**

Deprecated AArch32 functionality	Instruction enable or disable in the <b>SCTLR</b> <sup>a</sup>	Disabled instructions
SETEND instructions	SED <sup>b</sup>	<b>SETEND</b> instructions
Some uses of IT instructions	ITD <sup>c</sup>	See the <b>SCTLR</b> .ITD description
Accesses to the <b>CP15DMB</b> , <b>CP15DSB</b> , and <b>CP15ISB</b> barrier instructions	CP15BEN <sup>d</sup>	MCR accesses to the <b>CP15DMB</b> , <b>CP15DSB</b> , and <b>CP15ISB</b> instructions

- The controls that are implemented in **SCTLR** are also implemented in **SCTLR\_EL1**, and apply when PL1 is using AArch64 and PL0 is using AArch32.
- SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
- IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
- System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

———— **Note** ————

The uses of the IT instruction, and use of the **CP15DMB**, **CP15DSB**, and **CP15ISB** barrier instructions, are deprecated for performance reasons.

### Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers

If implemented, the **CPACR**.TRCDIS control traps PL0 and PL1 System register accesses to the trace registers to Undefined mode, as follows:

- |          |   |
|----------|---|
| <b>1</b> | PL0 and PL1 accesses to the System register interface to the trace macrocell are trapped to Undefined mode  |
| <b>0</b> | This control has no effect on PL0 and PL1 accesses to the System register interface to the trace macrocell. |

If the **CPACR**.TRCDIS control is not implemented, then the **CPACR**.TRCDIS field is RAZ/WI. This means the **CPACR** does not provide a trap to Undefined mode of PL1 and PL0 System register accesses to trace registers. See the register description for more information.

———— **Note** ————

- System register accesses to the trace macrocell use the (coproc==0b1110) encoding space.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace System registers are UNDEFINED.
- The ARMv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see *Register access instructions* on page G1-4419.

If EL3 is implemented and is using AArch32, and **NSACR**.NSTRCDIS is 1, **CPACR**.TRCDIS behaves as RAO/WI in Non-secure state. This behavior also applies if the **CPACR**.TRCDIS control is not implemented.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-4356.

## Enabling use of Advanced SIMD and floating-point functionality

Table G1-29 summarizes the controls of Advanced SIMD and floating-point functionality.

**Table G1-29 Controls of use of Advanced SIMD and floating-point functionality**

Control	Type	Description, see
CPACR.{cp11, cp10}	E	<i>Enabling PL0 and PL1 accesses to the SIMD and floating-point registers</i>
FPEXC.EN	E	<i>Enabling access to the SIMD and floating-point registers on page G1-4424</i>
CPACR.ASEDIS	D	<i>Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-4424</i>

If any of CPACR.{cp11, cp10}, FPEXC.EN, or for Advanced SIMD instructions, CPACR.ASEDIS, disable a floating-point or an Advanced SIMD instruction, the instruction is UNDEFINED. Support for the CPACR.ASEDIS control is optional, and if the control is not implemented behavior is as if the control permits the execution of Advanced SIMD instructions at PL1 and PL0.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2 on page G1-4356*.

### Enabling PL0 and PL1 accesses to the SIMD and floating-point registers

CPACR.{cp11, cp10} enable PL0 and PL1 accesses to the SIMD and floating-point registers.

When CPACR.cp10 is:

<b>00</b>	PL0 and PL1 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
<b>01</b>	PL0 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
<b>10</b>	Reserved. The effect of programming this field to this value is CONSTRAINED UNPREDICTABLE.
<b>11</b>	This control permits full access to the Advanced SIMD and floating-point functionality from PL0 and PL1.

The value of CPACR.cp11 is ignored. If CPACR.cp11 is programmed with a different value to CPACR.cp10 then CPACR.cp11 is UNKNOWN on a direct read of the CPACR.

#### ———— Note ————

- Software must set CPACR.cp11 and CPACR.cp10 to the same value.

Table G1-30 shows the registers for which accesses are enabled.

**Table G1-30 Register accesses enabled at PL0 and PL1 by CPACR.{cp11, cp10}**

Enabled at	Registers
PL0 and PL1, or PL0 only <sup>a</sup>	FPSCR, FPEXC, FPSID, MVFR0, MVFR1, MVFR2, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers <sup>b</sup>

a. Depending on the value of CPACR.{cp11, cp10}. See the register description for details.

b. Permitted VMSR accesses to the FPSID are ignored, but for the purposes of the {cp10, cp11} controls the architecture defines a VMSR accesses to the FPSID from EL1 or higher is an access to a SIMD and floating-point register.

If EL3 is implemented and is using AArch32, and NSACR.{cp11, cp10} are both set to 0, the functionality described in this section is disabled in Non-secure state, and CPACR.{cp11, cp10} are RAZ/WI in Non-secure state. See *Enabling Non-secure access to SIMD and floating-point functionality on page G1-4449*.

For more information about SIMD and floating-point support, see [Advanced SIMD and floating-point support on page G1-4412](#).

### Enabling access to the SIMD and floating-point registers

**FPEXC**.EN enables accesses to the SIMD and floating-point registers at all Exception levels, but does not control the following:

- VMSR accesses to the **FPEXC** or **FPSID**.
- VMRS accesses from the **FPEXC**, **FPSID**, **MVFR0**, **MVFR1**, or **MVFR2**.

When **FPEXC**.EN is:

- 1** Accesses to the registers shown in [Table G1-31](#) are enabled at all Exception levels.
- 0** All accesses to the registers shown in [Table G1-31](#) are UNDEFINED.

[Table G1-31](#) shows the registers for which accesses are enabled, and for an exception taken to Hyp mode, how the exception is reported in **HSR**.

**Table G1-31 Register accesses enabled when **FPEXC**.EN is 1**

Enabled at	Registers	Syndrome reporting in <b>HSR</b> <sup>a</sup>
All Exception levels	<b>FPSCR</b> , and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers.	Exception for an unknown reason, using EC value 0x00

- a. Only for exceptions that are taken to Hyp mode.

For more information, see [Advanced SIMD and floating-point support on page G1-4412](#).

### Disabling PL0 and PL1 execution of Advanced SIMD instructions

If implemented as an RW field, **CPACR**.ASEDIS can disable PL0 and PL1 execution of Advanced SIMD instructions, as follows:

- 1** Advanced SIMD instructions are UNDEFINED at PL0 and PL1.
- 0** Advanced SIMD instruction execution is enabled at PL0 and PL1.

The instructions that **CPACR**.ASEDIS disables are those described in [Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2746](#).

When the control is not implemented, meaning the **CPACR**.ASEDIS field is RAZ/WI, behavior is as if the control permits execution of Advanced SIMD instructions at PL0 and PL1.

If EL3 is implemented and is using AArch32, and **NSACR**.NSASEDIS is 1, **CPACR**.ASEDIS is RAO/WI in Non-secure state. This also applies when the **CPACR**.ASEDIS control is not implemented.

### Traps to Undefined mode of EL0 accesses to the Debug Communications Channel (DCC) registers

**DBGDSCRext**.UDCCdis traps EL0 accesses to the DCC registers to Undefined mode:

- 1** EL0 accesses to the DCC registers are trapped to Undefined mode
- 0** This control has no effect on EL0 accesses to the DCC registers.

Traps of EL0 accesses to the **DBGDTRRXint** and **DBGDTRTXint** are ignored in Debug state.

[Table G1-32](#) shows the registers for which accesses are trapped.

**Table G1-32 Register accesses trapped to Undefined mode when **DBGDSCRext**.UDCCdis is 1**

Traps from	Registers
EL0	<b>DBGDSCRint</b> , <b>DBGDTRRXint</b> , <b>DBGDTRTXint</b> , <b>DBGDIDR</b> , <b>DBGDSAR</b> , <b>DBGDRAR</b>

### Note

All accesses to these registers are trapped, including LDC and STC accesses to [DBGDTRTXint](#) and [DBGDTRRXint](#), and MRRC accesses to [DBGDSAR](#) and [DBGDRAR](#).

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356](#).

## Traps to Undefined mode of EL0 accesses to the Generic Timer registers

[CNTKCTL](#).{[PL0PTEN](#), [PL0VTEN](#), [PL0PCTEN](#), [PL0VCTEN](#)} trap EL0 accesses to the Generic Timer registers to Undefined mode, as follows:

- [CNTKCTL](#).[PL0PTEN](#) traps EL0 accesses to the physical timer registers.
- [CNTKCTL](#).[PL0VTEN](#) traps EL0 accesses to the virtual timer registers.
- [CNTKCTL](#).[PL0PCTEN](#) traps EL0 accesses to the frequency register and physical counter register.
- [CNTKCTL](#).[PL0VCTEN](#) traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:

- 1** This control has no effect on EL0 accesses to the corresponding registers.
- 0** EL0 accesses to the corresponding registers are trapped to Undefined mode.

Accesses to the frequency register, [CNTFRQ](#), are only trapped if [CNTKCTL](#).[PL0PCTEN](#) and [CNTKCTL](#).[PL0VCTEN](#) are both 0.

[Table G1-33](#) shows the registers for which accesses are trapped.

**Table G1-33 Register accesses trapped to Undefined mode by [CNTKCTL](#) trap controls**

Traps from	Trap control	Registers
EL0	<a href="#">PL0PTEN</a>	<a href="#">CNTP_CTL</a> , <a href="#">CNTP_CVAL</a> , <a href="#">CNTP_TVAL</a>
	<a href="#">PL0VTEN</a>	<a href="#">CNTV_CTL</a> , <a href="#">CNTV_CVAL</a> , <a href="#">CNTV_TVAL</a>
	<a href="#">PL0PCTEN</a>	<a href="#">CNTFRQ</a> , <a href="#">CNTPCT</a>
	<a href="#">PL0VCTEN</a>	<a href="#">CNTFRQ</a> , <a href="#">CNTVCT</a>

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-4356](#).

## Traps to Undefined mode of EL0 accesses to Performance Monitors registers

[PMUSERENR](#).{[ER](#), [CR](#), [SW](#), [EN](#)} trap EL0 accesses to the Performance Monitors registers to Undefined mode. For each of these controls:

- 1** This control has no effect on EL0 accesses to the corresponding registers.
- 0** EL0 accesses to the corresponding registers are trapped to Undefined mode.

For those Performance Monitors registers that more than one [PMUSERENR](#).{[ER](#), [CR](#), [SW](#), [EN](#)} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.

### Note

- The architecture does not provide traps on Performance Monitors register accesses through the memory-mapped external debug interface.
- If the Performance Monitors Extension is not implemented, the Performance Monitors registers, including [PMUSERENR](#), are reserved.

Table G1-34 shows the registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.

**Table G1-34 Register accesses trapped to Undefined mode when disabled from EL0**

Traps from	Trap control	Registers	Access type
EL0	ER	PMXVCNTR, PMEVCNTR<n>	R
		PMSELR	RW
	CR	PMCCNTR, accessed using an MRC	R
	CR	PMCCNTR, accessed using an MRRC	R
	SW	PMSWINC	W
	EN	PMCNTENSET, PMCNTENCLR, PMCR, PMOVSr, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXVCNTR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR	RW

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-4356.

## G1.20.3 EL2 configurable controls

These controls are ignored in Secure state.

Table G1-35 shows the System registers that contain these controls.

**Table G1-35 System registers that contain instruction enables and disables, and trap controls**

Register name	Register description
FPEXC	Floating-point Exception Control Register
HCR	Hypervisor Configuration Register
HSTR	Hypervisor System Trap Register
HCPtr	Hyp Architectural Feature Trap Register
HDCR	Hyp Debug Control Register

### Note

- FPEXC.EN is a control that is in a System register provided by PL1. However, some exceptions generated because the value of FPEXC.EN is 1 are taken to Hyp mode.
- For completeness, Table G1-36 includes the HCR.TGE routing control, that is described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-4356.

Table G1-36 summarizes the controls.

**Table G1-36 Instruction enables and disables, and trap controls, for exceptions taken to Hyp mode**

Control	Control type <sup>a</sup>	Description
HSCTLR.{SED, ITD}	D	Disabling or enabling EL2 use of AArch32 deprecated functionality on page G1-4430
HSCTLR.CP15BEN	E	
HCR.{TRVM, TVM}	T	Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-4430
HCR.HCD	D	Disabling Non-secure state execution of HVC instructions on page G1-4431
HCR.TGE	R	Routing exceptions from Non-secure EL0 to EL2 on page G1-4356
HCR.TTLB	T	Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions on page G1-4431
HCR.{TSW, TPC, TPU}	T	Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions on page G1-4432
HCR.TAC	T	Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register on page G1-4432
HCR.TIDCP	T	Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-4433
HCR.TSC	T	Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-4434
HCR.{TID0, TID1, TID2, TID3}	T	Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers on page G1-4434

**Table G1-36 Instruction enables and disables, and trap controls, for exceptions taken to Hyp mode (continued)**

Control	Control type <sup>a</sup>	Description
HCR.{TWI, TWE}	T	<i>Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437</i>
HCPTTR.{TCP11, TCP10}	T	<i>General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-4437</i>
FPEXC.EN	T	<i>Enabling access to the SIMD and floating-point registers on page G1-4438</i>
HCPTTR.TASE	T	<i>Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-4438</i>
HCPTTR.TCPAC	T	<i>Traps to Hyp mode of Non-secure EL1 accesses to the CPACR on page G1-4439</i>
HCPTTR.TTA	T	<i>Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-4439</i>
HSTR.{T0-T3, T5-T13, T15}	T	<i>General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc == 0b1111) encoding space on page G1-4440</i>

HDCR.{TPM, TPMCR}	T	<i>Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page G1-4444</i>

a. See Table G1-37.

**Table G1-37 Control types, for exceptions taken to Hyp mode**

Abbreviation	Type	See
D	Disable	<i>Instruction enables and instruction disables on page G1-4418</i>
E	Enable	<i>Instruction enables and instruction disables on page G1-4418</i>
R	Routing control	<i>Routing exceptions from Non-secure EL0 to EL2 on page G1-4356</i>
T	Trap	<i>Trap controls on page G1-4418</i>

Also see the following:

- *Register access instructions on page G1-4419.*
- *Instructions that fail their Condition code check on page G1-4429.*
- *Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-4429.*

## Instructions that fail their Condition code check

For UNDEFINED instructions that fail their Condition code check, see [Conditional execution of undefined instructions on page G1-4378](#).

For an instruction that has a Hyp trap set, that fails its Condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
  - Generates a Hyp Trap exception.
  - Executes as a NOP.

Any implementation must be consistent in its handling of instructions that fail their Condition code check. This means that:

- Whenever a Hyp trap is set on an instruction it must either:
  - Always generate a Hyp Trap exception.
  - Always treat the instruction as a NOP.
- The IMPLEMENTATION DEFINED part of the requirements of [Conditional execution of undefined instructions on page G1-4378](#) must be consistent with the handling of Hyp traps on instructions that fail their Condition code check. [Table G1-38](#) shows this:

**Table G1-38 Consistent handling of instructions that fail their Condition code check**

Behavior of conditional UNDEFINED instruction <sup>a</sup>	Hyp trap on instruction that fails its Condition code check <sup>b</sup>
Executes as a NOP	Executes as a NOP
Generates an Undefined Instruction exception	Generates a Hyp Trap exception
a. As defined in <a href="#">Conditional execution of undefined instructions on page G1-4378</a> . In Non-secure EL0 and EL1 modes, this applies only if no Hyp trap is set for the instruction, otherwise see the behavior in the other column of the table. b. For a trapped instruction executed in a Non-secure EL1 or EL0 mode.	

### ———— Note ————

Hyp traps on WFE and WFI instructions generate Hyp Trap exceptions only if the instruction passes its Condition code check. See [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437](#).

## Trapping to EL2 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates a Hyp Trap exception.

### ———— Note ————

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. This means that disabling or trapping an instruction changes the set of instructions that might be executed in Non-secure state at EL1 or EL0. This indirectly affects the permitted behavior of UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions.

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in a Non-secure EL1 or EL0 mode must not generate a Hyp Trap exception.

## Disabling or enabling EL2 use of AArch32 deprecated functionality

Table G1-39 shows the deprecated AArch32 functionality that might have disable controls in the [HSCTLR](#):

- The SED control is always implemented.
- Whether each of the ITD, CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

These [HSCTLR](#) controls apply only to execution at EL2 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL2, meaning it is undefined in Hyp mode.

**Table G1-39 EL2 controls for disabling and enabling EL2 use of AArch32 deprecated functionality**

Deprecated AArch32 functionality	Instruction enable or disable in the <a href="#">HSCTLR</a>	Disabled instructions
SETEND instructions	SED <sup>a</sup>	<a href="#">SETEND</a> instructions
Some uses of IT instructions	ITD <sup>b</sup>	See the <a href="#">HSCTLR.IT</a> description
Accesses to the System register (coproc==0b1111) DMB, DSB, and ISB barrier operations	CP15BEN <sup>c</sup>	MCR accesses to the <a href="#">CP15DMB</a> , <a href="#">CP15DSB</a> , and <a href="#">CP15ISB</a>

- SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
- IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
- System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

### ———— Note ————

- These controls have no effect on instructions executed in any mode other than Hyp mode. The [SCTLR](#) provides similar controls that apply to execution in other modes.
- The uses of the IT instruction, and use of the [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) barrier instructions, are deprecated for performance reasons.

## Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers

[HCR.{TRVM, TVM}](#) trap Non-secure EL1 accesses to the virtual memory control registers to Hyp mode:

### [HCR.TRVM](#), for read accesses:

- |          |   |
|----------|---|
| <b>1</b> | Non-secure EL1 reads of the virtual memory control registers are trapped to Hyp mode.       |
| <b>0</b> | This control has no effect on Non-secure EL1 reads of the virtual memory control registers. |

### [HCR.TVM](#), for write access:

- |          |  |
|----------|--|
| <b>1</b> | Non-secure EL1 writes to the virtual memory control registers are trapped to Hyp mode.       |
| <b>0</b> | This control has no effect on Non-secure EL1 writes to the virtual memory control registers. |

Table G1-40 on page G1-4431 shows the registers for which:

- Reads are trapped to Hyp mode when [HCR.TRVM](#) is 1.
- Writes are trapped to Hyp mode when [HCR.TVM](#) is 1.

The table also shows how the exceptions are reported in [HSR](#).

**Table G1-40 Register read and write accesses trapped when [HCR](#).{TRVM, TVM} are 1**

Traps from	Registers	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL1	<a href="#">SCTLR</a> , <a href="#">TTBR0</a> , <a href="#">TTBR1</a> , <a href="#">TTBCR</a> , <a href="#">TTBCR2</a> , <a href="#">DACR</a> , <a href="#">DFSR</a> , <a href="#">IFSR</a> , <a href="#">DFAR</a> , <a href="#">IFAR</a> , <a href="#">ADFSR</a> , <a href="#">AIFSR</a> , <a href="#">PRRR</a> , <a href="#">NMRR</a> , <a href="#">MAIR0</a> , <a href="#">MAIR1</a> , <a href="#">AMAIRO</a> , <a href="#">AMAIR1</a> , <a href="#">CONTEXTIDR</a>	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04

———— **Note** —————

These registers are not accessible at EL0.

### Disabling Non-secure state execution of HVC instructions

[HCR](#).HCD disables Non-secure state execution of HVC instructions:

- 1** HVC instructions are UNDEFINED at EL2 and Non-secure EL1. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.
- 0** HVC instruction execution is enabled at EL2 and Non-secure EL1.

———— **Note** —————

HVC instructions are always UNDEFINED at EL0.

[HCR](#).HCD is only implemented if EL3 is not implemented. Otherwise, it is RES0. See the [HCR](#) register description.

[Table G1-41](#) shows how the exceptions are reported in [HSR](#).

**Table G1-41 Instruction that causes exceptions when [HCR](#).HCD is 1**

Attempted execution in	Disabled instruction	Syndrome reporting in <a href="#">HSR</a>
Hyp mode	HVC	Exception for an unknown reason, using EC value 0x00
Mode other than Hyp mode	HVC	Not applicable

### Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the system instruction encoding space includes TLB maintenance instructions.

[HCR](#).TTLB traps Non-secure EL1 execution of TLB maintenance instructions to Hyp mode:

- 1** Any attempt to execute a TLBI instruction at Non-secure EL1 is trapped to Hyp mode.
- 0** This control has no effect on the Non-secure EL1 execution of TLBI instructions.

[Table G1-42](#) shows the instructions that are trapped, and how the exceptions are reported in [HSR](#).

**Table G1-42 Instructions trapped to Hyp mode when [HCR](#).TTLB is 1**

Traps from	Trapped instructions	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL1	<a href="#">TLBIALLIS</a> , <a href="#">TLBIMVAIS</a> , <a href="#">TLBIASIDIS</a> , <a href="#">TLBIMVAAIS</a> , <a href="#">TLBIMVALIS</a> , <a href="#">TLBIMVAALIS</a> , <a href="#">ITLBIALL</a> , <a href="#">ITLBIMVA</a> , <a href="#">ITLBIASID</a> , <a href="#">DTLBIALL</a> , <a href="#">DTLBIMVA</a> , <a href="#">DTLBIASID</a> , <a href="#">TLBIALL</a> , <a href="#">TLBIMVA</a> , <a href="#">TLBIASID</a> , <a href="#">TLBIMVAA</a> , <a href="#">TLBIMVAL</a> , <a href="#">TLBIMVAAL</a> .	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

———— **Note** ————

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see [The scope of TLB maintenance instructions](#) on page G4-4641.

### Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions

[HCR.{TSW, TPC, TPU}](#) trap cache maintenance instructions to Hyp mode:

- 0** The control has no effect on the execution of cache maintenance instructions.
- 1** Any attempt to execute one of the cache maintenance instructions shown in [Table G1-44](#) at Non-secure EL1 is trapped to Hyp mode.

**Table G1-43 Controls for trapping cache maintenance instructions to Hyp mode**

Trap control	Trapped instructions
<a href="#">HCR.TSW</a>	Data or unified cache maintenance by set/way
<a href="#">HCR.TPC</a>	Data or unified cache maintenance to point of coherency
<a href="#">HCR.TPU</a>	Cache maintenance to point of unification

[Table G1-44](#) shows the instructions that are trapped to Hyp mode, and how the exceptions are reported in [HSR](#).

**Table G1-44 Instructions trapped to Hyp mode when [HCR.{TSW, TPC, TPU}](#) are 1**

Traps from	Trap control	Trapped instructions	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL1	TSW	<a href="#">DCISW</a> , <a href="#">DCCSW</a> , <a href="#">DCCISW</a>	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x3
	TPC	<a href="#">DCIMVAC</a> , <a href="#">DCCIMVAC</a> , <a href="#">DCCMVAC</a>	
	TPU	<a href="#">ICIMVAU</a> , <a href="#">ICIALLU</a> , <a href="#">ICIALUIS</a> , <a href="#">DCCMVAU</a>	

———— **Note** ————

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see [Cache maintenance instructions, functional group](#) on page G4-4734.

### Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register

[HCR.TAC](#) traps Non-secure EL1 accesses to the Auxiliary Control Registers to Hyp mode:

- 1** Non-secure EL1 accesses to the Auxiliary Control Registers are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL1 accesses to the Auxiliary Control Registers.

[Table G1-45](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [HSR](#):

**Table G1-45 Register accesses trapped to Hyp mode when [HCR.TAC](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL1	<a href="#">ACTLR</a> and, if implemented, <a href="#">ACTLR2</a> .	Trapped MCR or MRC access (coproc==0b1111) access, using EC value 0x03

### Note

The [ACTLR](#) and [ACTLR2](#) are not accessible at EL0.

## Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARMv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

[HCR.TIDCP](#) traps the execution of System register access instructions that access these registers, as follows:

- 1 At Non-secure EL1, any attempt to execute an MCR or MRC instruction with a reserved register encoding shown in [Table G1-46](#) is trapped to Hyp mode.  
At Non-secure EL0, it is IMPLEMENTATION DEFINED whether attempts to execute MCR or MRC instructions with reserved register encodings are:
  - Trapped to Hyp mode.
  - UNDEFINED, and the PE takes the Undefined Instruction exception to Non-secure Undefined mode.
 Any lockdown fault in the memory system caused by the use of these operations in Non-secure state generates a Data Abort exception that is taken to Hyp mode.
- 0 This control has no effect on Non-secure EL0 and EL1 System register access instructions with reserved register encodings shown in [Table G1-46](#).

### Note

This means that a Hyp Trap exception taken from Non-secure EL1 to Hyp mode, generated because of a configuration setting in [HCR.TIDCP](#) is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because the register is never accessible at EL1. As *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2.

[Table G1-46](#) shows the register encodings for which accesses are trapped to Hyp mode, and how the exceptions are reported in [HSR](#).

**Table G1-46 Encodings trapped to Hyp mode when [HCR.TIDCP](#) is 1**

Traps from	Register encodings	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL0 and EL1	An access to any of the following encodings: <ul style="list-style-type: none"> <li>• CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}.</li> <li>• CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}.</li> <li>• CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}.</li> </ul>	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

### Note

ARM expects the trapping of Non-secure User mode accesses to these functions to Hyp mode to be unusual, and used only when the hypervisor is virtualizing User mode operation. ARM strongly recommends that unless the hypervisor must virtualize User mode operation, a Non-secure User mode access to any of these functions generates an Undefined Instruction exception, as it would if the implementation did not include EL2. The PE then takes this exception to Non-secure Undefined mode.

## Traps to Hyp mode of Non-secure EL1 execution of SMC instructions

**HCR.TSC** traps Non-secure EL1 execution of SMC instructions to Hyp mode:

- 1** Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of **SCR.SCD**.
- 0** This control has no effect on Non-secure EL1 execution of SMC instructions.

Table G1-47 shows how the exceptions are reported in **HSR**:

**Table G1-47 SMC Instruction trapped to Hyp mode when **HCR.TSC** is 1**

Traps from	Trapped instruction	Syndrome reporting in <b>HSR</b>
Non-secure EL1	<a href="#">SMC on page F5-3429</a>	Trapped SMC instruction execution in AArch32 state, using EC value 0x13

The ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their Condition code check, in the same way as with traps on other conditional instructions.

### ———— Note ————

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are always UNDEFINED at EL0.
- **HCR.TSC** traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap and SMC exceptions have different preferred return addresses.

For more information about SMC instructions, see [SMC on page F5-3429](#).

## Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers

Other than the **MIDR**, **MPIDR**, and **PMCR.N**, the ID registers are divided into groups, with a trap control in the **HCR** for each group.

**Table G1-48 ID register groups**

Trap control	Register group
<b>HCR.TID0</b>	<i>ID group 0, Primary device identification registers on page G1-4435</i>
<b>HCR.TID1</b>	<i>ID group 1, Implementation identification registers on page G1-4436</i>
<b>HCR.TID2</b>	<i>ID group 2, Cache identification registers on page G1-4436</i>
<b>HCR.TID3</b>	<i>ID group 3, Detailed feature identification registers on page G1-4436</i>

These controls trap register accesses from Non-secure EL0 or EL1 to Hyp mode, as follows:

- HCR.TID0**
  - 0** This control has no effect on Non-secure EL1 reads of the ID group 0 registers.
  - 1** Any attempt at Non-secure EL0 or EL1 to read any register in ID group 0 is trapped to Hyp mode
- HCR.TID1**
  - 0** This control has no effect on Non-secure EL1 reads of the ID group 1 registers.
  - 1** Any attempt at Non-secure EL1 to read any register in ID group 1 is trapped to Hyp mode.
- HCR.TID2**
  - 0** This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.
  - 1** Any attempt at Non-secure EL0 or EL1 to read any register in ID group 2, and any attempt at Non-secure EL0 or EL1 to write to the **CSSELR**, is trapped to Hyp mode.

<b>HCR.TID3</b>	<b>0</b>	This control has no effect on Non-secure EL1 reads of the ID group 3 registers.
	<b>1</b>	Any attempt at Non-secure EL1 to read any register in ID group 3 is trapped to Hyp mode.

For the [MIDR](#) and [MPIDR](#), and for [PMCR.N](#), the architecture provides read/write aliases. The original register becomes accessible only from Hyp mode and Secure state, and a Non-secure EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

**Table G1-49 ID register substitution**

Register	Original	Alias, EL2 using AArch32
Main ID	<a href="#">MIDR</a>	<a href="#">VPIDR</a>
Multiprocessor Affinity	<a href="#">MPIDR</a>	<a href="#">VMPIDR</a>
Performance Monitors Control Register	<a href="#">PMCR.N</a>	<a href="#">HDCR.HPMN</a>

Reads of the [MIDR](#), [MPIDR](#), or [PMCR.N](#) from Hyp mode or Secure state are unchanged by the implementation of EL2, and access the physical registers.

**Note**

- If the optional Performance Monitors Extension is not implemented, [HDCR.HPMN](#) is RES0 and [PMCR](#) is reserved.
- [HDCR.HPMN](#) also affects whether a Performance Monitors counter can be accessed from Non-secure EL1 or EL0. See the register description of [HDCR](#) for more information.
- [PMCR](#) contains other fields that identify the implementation. For more information about trapping accesses to the [PMCR](#), see [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page G1-4444](#).

A reset into AArch32 state sets [VPIDR](#) to the [MIDR](#) value, [VMPIDR](#) to the [MPIDR](#) value, and [HDCR.HPMN](#) to the [PMCR.N](#) value.

**ID group 0, Primary device identification registers**

These registers identify some top-level implementation choices.

[Table G1-50](#) shows the registers that are in ID group 0 for traps to Hyp mode, and how the exceptions are reported in [HSR](#).

**Table G1-50 ID group 0 registers**

Traps from	Group 0 registers	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL1	<a href="#">FPSID</a>	Trapped VMRS access, for ID group traps, using EC value 0x08
Non-secure EL0 and EL1	<a href="#">JIDR</a>	Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05

**Note**

The [FPSID](#) is not accessible at EL0.

If [HCPTR](#).{TCP11, TCP10} traps accesses to SIMD and floating-point functionality, then for a read of [FPSID](#), that trap has priority over this trap.

When the [FPSID](#) is accessible, a VMRS [FPSID](#), <Rt> instruction is permitted but is ignored. The execution of this VMRS instruction is not trapped by the ID group 0 trap.

### ID group 1, Implementation identification registers

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table G1-51 shows the registers that are in ID group 1 for traps to Hyp mode, and how the exceptions are reported in HSR.

Table G1-51 ID group 1 registers

Traps from	Group 1 registers	Syndrome reporting in HSR
Non-secure EL1	TCMTR, TLBTR, REVIDR, AIDR	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

### ID group 2, Cache identification registers

These registers describe and control the cache implementation.

Table G1-52 shows the registers that are in ID group 2 for traps to Hyp mode, and how the exceptions are reported in HSR.

Table G1-52 ID group 2 registers

Traps from	Group 2 registers	Syndrome reporting in HSR
Non-secure EL0 and EL1	CTR, CCSIDR, CLIDR, CSSELR	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

### ID group 3, Detailed feature identification registers

These registers provide detailed information about the features of the implementation.

#### ———— Note ————

These registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See *The CPUID identification scheme on page G4-4728*.

Table G1-53 shows the registers that are in ID group 3 for traps to Hyp mode, and how the exceptions are reported in HSR.

Table G1-53 ID group 3 registers

Traps from	Group 3 registers	Syndrome reporting in HSR
Non-secure EL1	MVFR0, MVFR1, MVFR2.	Trapped VMRS access for ID group traps, using EC value 0x08
	<p>ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0.</p> <p>ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4, except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether reads of the register are trapped.</p> <p>ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5.</p> <p>Any MRC access to any of the following encodings when coproc==0b1111:</p> <ul style="list-style-type: none"> <li>opc1 == 0, CRn == c0, CRm == {c3-c7}, opc2 == {0, 1}.</li> <li>opc1 == 0, CRn == c0, CRm == c3, opc2 == 2.</li> <li>opc1 == 0, CRn == c0, CRm == c5, opc2 == {4, 5}.</li> </ul> <p>It is IMPLEMENTATION DEFINED whether HCR.TID3 traps MRC accesses with coproc==0b1111 to encodings in the following range that are not already mentioned in this table:</p> <ul style="list-style-type: none"> <li>CRn == c0, opc1 == 0, CRm == {c2-c7}, opc2 == {0-7}.</li> </ul>	<p>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</p>

If **HCPTR** traps accesses to SIMD and floating-point functionality, then for reads of **MVFR0**, **MVFR1**, and **MVFR2**, that trap has priority over this trap.

### Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions

**HCR**.{TWE, TWI} trap Non-secure EL0 and EL1 execution of WFE and WFI instructions to Hyp mode:

#### **HCR.TWE:**

- 1** Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** This control has no effect on Non-secure EL0 or EL1 execution of WFE instructions.

#### **HCR.TWI:**

- 1** Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** This control has no effect on Non-secure EL0 or EL1 execution of WFI instructions.

Table G1-54 shows how the exceptions are reported in **HSR**.

**Table G1-54 Instructions trapped to Hyp mode when **HCR**.{TWE, TWI} are 1**

Traps from	Trapped instructions	Syndrome reporting in <b>HSR</b>
Non-secure EL0 and EL1	WFE	Trapped WFI or WFE instruction, using EC value 0x01
	WFI	

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

#### ———— **Note** ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait For Event and Send Event on page G1-4403](#).
- [Wait For Interrupt on page G1-4406](#).

### General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers

**HCPTR**.{TCP11, TCP10} trap Non-secure accesses to the SIMD and floating-point registers to Hyp mode:

- 0b11** All Non-secure accesses to the SIMD and floating-point registers are trapped to Hyp mode. Trapped instructions generate:
  - Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
  - Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.
- 0b00** This control has no effect on Non-secure accesses to the SIMD and floating-point registers.

#### ———— **Note** ————

Software must set **HCPTR**.TCP11 and **HCPTR**.TCP10 to the same value.

Table G1-55 shows the registers for which accesses are trapped, and how the exceptions are reported in [HSR](#).

**Table G1-55 Register accesses trapped to Hyp mode when [HCPTR](#).{TCP11, TCP10} are both 0b11**

Traps from	Registers	Syndrome reporting in <a href="#">HSR</a>
Non-secure state	<a href="#">FPSID</a> , <a href="#">MVFR0</a> , <a href="#">MVFR1</a> , <a href="#">MVFR2</a> , <a href="#">FPSCR</a> , <a href="#">FPEXC</a> , and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See <a href="#">Advanced SIMD and floating-point System registers on page G1-4415</a> .	Trapped access to SIMD and floating-point register, resulting from <a href="#">HCPTR</a> , using EC value 0x07 <sup>a</sup>

- a. VMSR accesses to the [FPSID](#) are ignored, but for the purposes of this trap the architecture defines a VMSR access to the [FPSID](#) from EL1 or higher as an access to a SIMD and floating-point register.

If EL3 is implemented and is using AArch32, and [NSACR](#).{cp11, cp10} are both set to 0, then [HCPTR](#).{TCP11, TCP10} behave as RAO/WI, regardless of their actual value.

For more information about SIMD and floating-point support, see [Advanced SIMD and floating-point support on page G1-4412](#).

### Enabling access to the SIMD and floating-point registers

[FPEXC](#).EN is an instruction enable that enables access to the SIMD and floating-point registers from all Exception levels, but does not control the following:

- VMSR accesses to the [FPEXC](#) or [FPSID](#).
- VMSR accesses from the [FPEXC](#), [FPSID](#), [MVFR0](#), [MVFR1](#), or [MVFR2](#).

[FPEXC](#).EN is a PL1 control that also applies at EL2. See [Enabling access to the SIMD and floating-point registers on page G1-4424](#).

### Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality

If implemented as an RW field, [HCPTR](#).TASE can trap Non-secure execution of Advanced SIMD instructions to Hyp mode, as follows. This trap applies only when [HCPTR](#).{TCP11, TCP10} are both 0:

- 1** Any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode. Trapped instructions generate:
- Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
  - Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.
- 0** This control has no effect on Non-secure execution of Advanced SIMD instructions.

When the control is not implemented, meaning the [HCPTR](#).TASE field is RAZ/WI, the [HCPTR](#) does not provide a trap to Hyp mode of the Non-secure execution of Advanced SIMD instructions, other than the [HCPTR](#).{TCP11, TCP10} trap that applies to Non-secure execution of both Advanced SIMD and floating-point instructions.

Table G1-30 on page G1-4423 shows the instructions that are trapped, and how the exceptions are reported in [HSR](#).

**Table G1-56 Instructions trapped to Hyp mode when [HCPTR](#).TASE is set to 1**

Traps from	Instructions	Syndrome reporting in <a href="#">HSR</a>
Non-secure state	All Advanced SIMD instructions that are not also floating-point instructions. For more information see <a href="#">Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2746</a> .	Trapped access to SIMD and floating-point register, resulting from <a href="#">HCPTR</a> , using EC value 0x07

If EL3 is implemented and is using AArch32, and **NSACR.NSASEDIS** is 1, then **HCPTR.TASE** behaves as RAO/WI, regardless of its actual value. This behavior also applies when the **HCPTR.TASE** control is not implemented.

### Traps to Hyp mode of Non-secure EL1 accesses to the CPACR

**HCPTR.TCPAC** traps Non-secure EL1 accesses to the **CPACR** to Hyp mode:

- 1** Non-secure EL1 accesses to the **CPACR** are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL1 accesses to the **CPACR**.

Table G1-57 shows how the exceptions are reported in **HSR**:

**Table G1-57 Register accesses trapped to Hyp mode when **HCPTR.TCPAC** is 1**

Traps from	Register	Syndrome reporting in <b>HSR</b>
Non-secure EL1	<b>CPACR</b>	Trapped MCR or MRC access to System register with coproc==0b1111, using EC value 0x03

#### ———— Note ————

- The **CPACR** is not accessible at EL0.
- In ARMv7 and earlier versions of the ARM architecture, one use of the **CPACR** is to identify what coprocessor, or conceptual coprocessor, functionality is implemented. Legacy software might use this identification mechanism. A hypervisor can use this trap to emulate this mechanism. See [Background to the System register interface on page G1-4410](#) for more information about this functionality.

### Traps to Hyp mode of Non-secure System register accesses to trace registers

If implemented, the **HCPTR.TTA** control traps System register accesses to the trace registers from Non-secure state to Hyp mode, as follows:

- 1** Non-secure System register accesses to the trace registers are trapped to Hyp mode. Trapped instructions generate:
  - Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
  - Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.
- 0** This control has no effect on Non-secure System register accesses to the trace registers.

If the **HCPTR.TTA** control is not implemented, then **HCPTR.TTA** is RAO/WI. See the register description for more information.

#### ———— Note ————

- System register accesses to the trace registers use the System register (coproc==0b1110) encoding space.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefined Instruction exception is higher priority than an **HCPTR.TTA** Hyp Trap exception.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see [Register access instructions on page G1-4419](#).

Table G1-58 shows the registers for which accesses are trapped to Hyp mode when **HCPTR.TTA** is 1, and how the exceptions are reported in **HSR**.

**Table G1-58 Register accesses trapped to Hyp mode when **HCPTR.TTA** is 1**

Traps from	Registers	Syndrome reporting in <b>HSR</b>
Non-secure state	System register accesses to all implemented trace registers	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.</li> </ul>

If EL3 is implemented and is using AArch32, and **NSACR.NSTRCDIS** is 1, then **HCPTR.TTA** behaves as RAO/WI, regardless of its actual value. This behavior applies, also, when the **HCPTR.TTA** control is not implemented.

### General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space

**HSTR**.{T0-T3, T5-T13, T15} trap Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, or MRRC instructions, to the System registers in the (coproc==0b1111) encoding space, by:

- The value of the CRn argument to the instruction, for MCR and MRC instructions.
- The value of the CRm argument to the instruction, for MCRR and MRRC instructions.

This applies for the set of CRn, or CRm, values {c0-c3, c5-c13, c15}.

When an **HSTR.Tn** trap control is:

- 1** Non-secure EL1 accesses to the corresponding System registers in the (coproc==0b1111) encoding space are trapped to Hyp mode.  
EL0 accesses to the corresponding System registers are trapped to Hyp mode if they would not be UNDEFINED if the bit was zero.
- 0** This control has no effect on Non-secure EL0 or EL1 accesses to System registers.

#### ————— **Note** —————

This means that a Hyp Trap exception taken from EL1 to EL2, generated because of a configuration setting in **HSTR.Tn**, is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because a register is never accessible at Non-secure EL1. As *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2. This prioritization includes any access from Non-secure EL1 to a register that is only accessible in Secure state. So, for example, an access to the **SCR** from Non-secure EL1:

- When the value of **HSTR.T1** is 0, generates an Undefined Instruction exception.
- When the value of **HSTR.T1** is 1, generates a Hyp Trap exception.

Table G1-59 shows the accesses that are trapped, and how the exceptions are reported in **HSR**.

**Table G1-59 Accesses trapped to Hyp mode when an **HSTR.Tn** trap is enabled**

Traps from	Trap control	Trapped accesses	Syndrome reporting in <b>HSR</b>
Non-secure EL0 and EL1 <sup>a</sup>	Tn	MCR and MRC instructions, with coproc set to 0b1111 and CRn set to n	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03
		MCRR and MRRC instructions, with coproc set to 0b1111 and CRm set to n	Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04

- a. As described in this section, traps from EL1 apply whenever the value of **HSTR.Tn** is 1. Traps from EL0 apply only if the value of **HSTR.Tn** is 1 and the access would not be UNDEFINED if the value of **HSTR.Tn** was 0.

For example, when **HSTR.T7** is 1, considering only accesses from Non-secure EL1:

- Any 32-bit access from a Non-secure PL1 mode using an MRC or MCR instruction with coproc set to 0b1111 and CRn set to c7, is trapped to Hyp mode.
- Any 64-bit access from a Non-secure PL1 mode using an MRRC or MCRR instructions with coproc set to 0b1111 and CRm set to c7, is trapped to Hyp mode.

---

**Note**

- Bits[4,14] of the **HSTR** are reserved, RES0. Although the Generic Timer control registers are implemented in the coproc == 0b1111 encoding space with CRn == c14 for an MRC or MCR access, EL2 does not provide a trap on accesses to the Generic Timer System registers.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of trapping of IMPLEMENTATION DEFINED features.

---

**System registers in the (coproc==0b1111) encoding space with IMPLEMENTATION DEFINED access permission from EL0**

For a System register in the (coproc==0b1111) encoding space, that is accessed using a CRn or CRm value that can be trapped by a **HSTR.Tn** control, if an access to the register from User mode is UNDEFINED when the value of the corresponding **HSTR.Tn** trap control is 0, then when that **HSTR.Tn** trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure User mode generates:

- A Hyp Trap exception.
- An Undefined Instruction exception taken to Non-secure Undefined mode.

---

**Note**

ARM expects that trapping to Hyp mode of Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space will be unusual, and used only when the hypervisor must virtualize User mode operation. ARM recommends that, whenever possible, Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space behave as they would if the processor did not implement EL2, generating an Undefined Instruction exception taken to Non-secure Undefined mode if the architecture does not support the User mode access.

---

**Traps to Hyp mode of Non-secure System register accesses to debug registers**

**HDCR**.{TDRA, TDOSA, TDA} trap Non-secure System register accesses to debug registers to Hyp mode, as follows:

- **HDCR**.{TDRA, TDA} trap Non-secure EL0 and EL1 accesses.
- **HDCR**.TDOSA traps Non-secure EL1 accesses.

---

**Note**

EL2 does not provide traps of debug register accesses through the optional memory-mapped external debug interface.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to Hyp mode, no side-effects occur before the exception is taken to Hyp mode. See [Register access instructions on page G1-4419](#).

Table G1-60 shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in [HSR](#).

**Table G1-60 Traps of Non-secure EL0 and EL1 accesses to debug registers**

Trap control	Subsection
HDCR.TDRA	<a href="#">Trapping Non-secure System register accesses to Debug ROM registers</a>
HDCR.TDOSA	<a href="#">Trapping Non-secure System register accesses to powerdown debug registers</a>
HDCR.TDA	<a href="#">Trapping general Non-secure System register accesses to debug registers on page G1-4443</a>

———— **Note** ————

System register accesses to debug registers use the (coproc==0b1110) encoding space.

**Trapping Non-secure System register accesses to Debug ROM registers**

[HDCR.TDRA](#) traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode:

- |          |   |
|----------|---|
| <b>1</b> | Non-secure EL0 or EL1 System register accesses to the Debug ROM registers are trapped to Hyp mode.        |
| <b>0</b> | This control has no effect on Non-secure EL0 and EL1 System register accesses to the Debug ROM registers. |

[Table G1-61](#) shows the register accesses that are trapped, and how the exceptions are reported in [HSR](#):

**Table G1-61 Register accesses trapped to Hyp mode when [HDCR.TDRA](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL0 and EL1	<a href="#">DBGDRAR</a> , <a href="#">DBGDSAR</a>	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</li> <li>MRRC instructions, trapped MRRC access (coproc==0b1110), using EC value 0x0C.</li> </ul>

If [HDCR.TDE](#) or [HCR.TGE](#) is 1, behavior is as if [HDCR.TDRA](#) is 1 other than for the purpose of a direct read.

**Trapping Non-secure System register accesses to powerdown debug registers**

[HDCR.TDOSA](#) traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode:

- |          |   |
|----------|---|
| <b>1</b> | Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.       |
| <b>0</b> | This control has no effect on Non-secure EL1 System register accesses to the powerdown debug registers. |

[Table G1-62](#) shows the register accesses that are trapped, and how the exceptions are reported in [HSR](#).

**Table G1-62 Register accesses trapped to Hyp mode when [HDCR.TDOSA](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL1	<a href="#">DBGOSLSR</a> , <a href="#">DBGOSLAR</a> , <a href="#">DBGOSDLR</a> , <a href="#">DBGPRCR</a> Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by <a href="#">HDCR.TDOSA</a> .	Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05

### Note

These registers are not accessible at EL0.

If [HDCR.TDE](#) or [HCR.TGE](#) is 1, behavior is as if [HDCR.TDOSA](#) is 1 other than for the purpose of a direct read.

### Trapping general Non-secure System register accesses to debug registers

[HDCR.TDA](#) traps Non-secure EL0 and EL1 System register accesses to the debug registers that are not mentioned in either of the following:

- [Traps to Hyp mode of Non-secure System register accesses to debug registers on page G1-4441.](#)
- [Trapping Non-secure System register accesses to powerdown debug registers on page G1-4442.](#)

This means that [HDCR.TDA](#) traps to Hyp mode Non-secure EL0 and EL1 System register accesses to all debug registers except the following:

- Non-secure System register accesses to [DBGDRAR](#) or [DBGDSAR](#). The [HDCR.TDRA](#) trap traps these accesses.
- Non-secure System register access to [DBGOSLSR](#), [DBGOSLAR](#), [DBGOSDLR](#), or [DBGPRCR](#). The [HDCR.TDOSA](#) trap traps these accesses.

[HDCR.TDA](#) does not trap accesses to [DBGDTRTXint](#) or [DBGDTRRXint](#) when the PE is in Debug state.

When [HDCR.TDA](#) is:

- 1** Non-secure EL0 or EL1 System register accesses to any of the registers shown in [Table G1-63](#) are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL0 or EL1 System register accesses.

[Table G1-63](#) shows how the exceptions are reported in [HSR](#).

**Table G1-63 Accesses trapped to Hyp mode when [HDCR.TDA](#) is 1**

Traps from	Trapped accesses	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL0 and EL1	Accesses to the <a href="#">DBGDIDR</a> , <a href="#">DBGDSCRint</a> , <a href="#">DBGDCCINT</a> , <a href="#">DBGDTRRXint</a> , <a href="#">DBGDTRTXint</a> , <a href="#">DBGWFR</a> , <a href="#">DBGVCR</a> , <a href="#">DBGDSCRext</a> , <a href="#">DBGDTRTXext</a> , <a href="#">DBGDTRRXext</a> , <a href="#">DBGBVR&lt;n&gt;</a> , <a href="#">DBGBCR&lt;n&gt;</a> , <a href="#">DBGBXVR&lt;n&gt;</a> , <a href="#">DBGWCR&lt;n&gt;</a> , <a href="#">DBGWVR&lt;n&gt;</a> , <a href="#">DBGCLAIMSET</a> , <a href="#">DBGCLAIMCLR</a> , <a href="#">DBGAUTHSTATUS</a> , <a href="#">DBGDEVID</a> , <a href="#">DBGDEVID1</a> , <a href="#">DBGDEVID2</a> , and <a href="#">DBGOSECRR</a>	For accesses using MCR or MRC instructions, trapped MCR or MRC access (coproc == 0b1110), using EC value 0x05
	STC accesses to <a href="#">DBGDTRRXint</a> .	Trapped LDC or STC access, using EC value 0x06
	LDC accesses to <a href="#">DBGDTRTXint</a> .	

If [HDCR.TDE](#) or [HCR.TGE](#) is 1, behavior is as if [HDCR.TDA](#) is 1 other than for the purpose of a direct read.

### Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the Generic Timer registers

[CNTHCTL](#).{PL1PCEN, PL1PCTEN} trap Non-secure EL0 and EL1 accesses to the Generic Timer registers to Hyp mode, as follows:

- [CNTHCTL.PL1PCEN](#) traps Non-secure EL0 and EL1 accesses to the physical timer registers.
- [CNTHCTL.PL1PCTEN](#) traps Non-secure EL0 and EL1 accesses to the physical counter register.

For each of these controls:

- 1** This control has no effect on Non-secure EL0 and EL1 accesses to the registers shown in [Table G1-64 on page G1-4444.](#)

**0** Non-secure EL0 and EL1 accesses are trapped to Hyp mode.

Table G1-64 shows the registers for which accesses are trapped, and how the exceptions are reported in [HSR](#).

**Table G1-64 Register accesses trapped to Hyp mode by [CNTHCTL](#) trap controls**

Traps from	Trap control	Registers	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL0 and EL1	PL1PCEN	<a href="#">CNTP_CTL</a> , <a href="#">CNTP_CVAL</a> , <a href="#">CNTP_TVAL</a>	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04</li> </ul>
	PL1PCTEN	<a href="#">CNTPCT</a>	Trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x04

### Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers

If the Performance Monitors Extension is implemented, [HDCR](#).{TPM, TPMCR} trap Non-secure EL0 and EL1 accesses to the Performance Monitors registers to Hyp mode:

#### [HDCR](#).TPM:

- 1** Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors registers.

#### [HDCR](#).TPMCR:

- 1** Non-secure EL0 and EL1 accesses to the Performance Monitors Control Register are trapped to Hyp mode.
- Note**
- The conditions for this trap are identical to those for the trap controlled by [HDCR](#).TPM
- 0** This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers.

#### **Note**

- EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.
- If the Performance Monitors Extension is not implemented, [HDCR](#).{TPM, TPMCR} are RES0.

Table G1-65 shows the registers for which accesses are trapped, and how the exceptions are reported in [HSR](#).

**Table G1-65 Register accesses trapped to Hyp mode when [HDCR](#).{TPM, TPMCR} are 1**

Traps from	Trap control	Registers	Syndrome reporting in <a href="#">HSR</a>
Non-secure EL0 and EL1	TPM	<a href="#">PMCR</a> , <a href="#">PMCNTENSET</a> , <a href="#">PMCNTENCLR</a> , <a href="#">PMOVSr</a> , <a href="#">PMSWINC</a> , <a href="#">PMSELR</a> , <a href="#">PMCEID0</a> , <a href="#">PMCEID1</a> , <a href="#">PMCCNTR</a> , <a href="#">PMXEVTYPER</a> , <a href="#">PMXVCNTR</a> , <a href="#">PMUSERENR</a> , <a href="#">PMINTENSET</a> , <a href="#">PMINTENCLR</a> , <a href="#">PMOVSSET</a> , <a href="#">PMEVCNTR</a> <n>, <a href="#">PMEVTYPER</a> <n>, <a href="#">PMCCFILTR</a>	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03.</li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04.</li> </ul>
	TPMCR	<a href="#">PMCR</a>	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

———— **Note** ————

[HDCR](#).HPMN affects whether a counter can be accessed from Non-secure EL1 or EL0. See the register description of [HDCR](#) for more information.

## G1.20.4 EL3 configurable controls

Table G1-66 shows the System registers that contain these controls.

**Table G1-66 System registers that contain instruction enables and disables, and trap controls**

Register name	Register description
SCR	Secure Configuration Register
NSACR	Non-secure Access Control Register

Table G1-67 summarizes the controls.

**Table G1-67 EL3 Instruction enables and disables, and trap controls**

Control	Type of control <sup>a</sup>	Trap
SCR.{TWE, TWI}	T	<i>Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-4447</i>
SCR.HCE	E	<i>Enabling EL2 and Non-secure EL1 execution of HVC instructions on page G1-4448</i>
SCR.SCD	D	<i>Disabling SMC instructions on page G1-4448</i>
NSACR.NSTRCDIS	D	<i>Disabling Non-secure System register access to the trace registers on page G1-4449</i>
NSACR.{cp11, cp10}	E	<i>Enabling Non-secure access to SIMD and floating-point functionality on page G1-4449</i>
NSACR.NSASEDIS	D	<i>Disabling Non-secure access to Advanced SIMD functionality on page G1-4450</i>

a. See Table G1-68.

**Table G1-68 Control types, for AArch32 EL3 controls**

Abbreviation	Type	See
D	Disable	<i>Instruction enables and instruction disables on page G1-4418</i>
E	Enable	<i>Instruction enables and instruction disables on page G1-4418</i>
T	Trap	<i>Trap controls on page G1-4418</i>

Also see the following:

- *Register access instructions on page G1-4419.*
- *Instructions that fail their Condition code check.*
- *Trapping to EL3 of instructions that are UNPREDICTABLE on page G1-4447.*

### Instructions that fail their Condition code check

For UNDEFINED instructions that fail their Condition code check, see *Conditional execution of undefined instructions on page G1-4378*.

For an instruction that has a Monitor trap set, that fails its Condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
  - Generates a Monitor Trap exception.
  - Executes as a NOP.

Any implementation must be consistent in its handling of instructions that fail their Condition code check. This means that:

- Whenever a Monitor trap is set on such an instruction it must either:
  - Always generate a Monitor trap exception.
  - Always treat the instruction as a NOP.
- The IMPLEMENTATION DEFINED part of the requirements of *Conditional execution of undefined instructions* on page G1-4378 must be consistent with the handling of Monitor traps on instructions that fail their Condition code check. Table G1-69 shows this:

**Table G1-69 Consistent handling of instructions that fail their Condition code check**

Behavior of conditional UNDEFINED instruction <sup>a</sup>	Monitor trap on instruction that fails its Condition code check <sup>b</sup>
Executes as a NOP	Executes as a NOP
Generates an Undefined Instruction exception	Generates a Monitor trap exception

- a. As defined in *Conditional execution of undefined instructions* on page G1-4378. In Non-secure EL0 and EL1 modes, this applies only if no Monitor trap is set for the instruction, otherwise see the behavior in the other column of the table.
- b. For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

———— **Note** ————

When  $\text{SCR}\{\text{TWE}, \text{TWI}\}$  is set so that conditional WFE and WFI instructions are trapped to Monitor mode, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check. See *Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode*.

## Trapping to EL3 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates a Monitor Trap exception.

———— **Note** ————

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. This means that disabling or trapping an instruction changes the set of instructions that might be executed in modes other than Monitor mode. This affects, indirectly, the permitted behavior of UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions.

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in a mode other than Monitor mode must not generate a Monitor Trap exception.

## Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode

$\text{SCR}\{\text{TWE}, \text{TWI}\}$  trap WFE and WFI instructions to Monitor mode:

$\text{SCR.TWE}$	<b>1</b>	Any attempt to execute a WFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.
	<b>0</b>	This control has no effect on the execution of WFE instructions.

<b>SCR.TWI</b>	<b>1</b>	Any attempt to execute a WFI instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.
	<b>0</b>	This control has no effect on the execution of WFI instructions.

For PL0 and PL1, these traps apply to WFE and WFI instruction execution in both Security states.

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

#### ———— **Note** ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait For Event and Send Event on page G1-4403.](#)
- [Wait For Interrupt on page G1-4406.](#)

## Enabling EL2 and Non-secure EL1 execution of HVC instructions

[SCR.HCE](#) enables EL2 and Non-secure EL1 execution of HVC instructions:

<b>1</b>	HVC instruction execution is enabled at EL2 and Non-secure EL1.
<b>0</b>	HVC instructions are: <ul style="list-style-type: none"> <li>• UNDEFINED at Non-secure EL1. The Undefined Instruction exception is taken to Undefined mode.</li> <li>• CONSTRAINED UNPREDICTABLE at EL2. The behavior must be one of the following: <ul style="list-style-type: none"> <li>— The instruction is UNDEFINED.</li> <li>— The instruction executes as a NOP.</li> </ul> </li> </ul>

#### ———— **Note** ————

- If EL2 is not implemented, [SCR.HCE](#) is RES0 and HVC is UNDEFINED.
- HVC instructions are always UNDEFINED at EL0 and in Secure state.

## Disabling SMC instructions

[SCR.SCD](#) disables SMC instructions:

<b>1</b>	<p><b>In Non-secure state</b></p> <p>SMC instructions are UNDEFINED. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.</p> <p><b>In Secure state</b></p> <p>Behavior is one of the following:</p> <ul style="list-style-type: none"> <li>• The instruction is UNDEFINED.</li> <li>• The instruction executes as a NOP.</li> </ul>
<b>0</b>	SMC instructions are enabled.

#### ———— **Note** ————

- SMC instructions are always UNDEFINED at EL0.

- When the value of `HCR.TSC` is 1, any attempted execution of an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of `SCR.SCD`, see [Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-4434](#). As [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to a higher Exception level.

## Disabling Non-secure System register access to the trace registers

`NSACR.NSTRCDIS` disables Non-secure System register accesses to the trace registers, from all Privilege levels:

- |          |  |
|----------|--|
| <b>1</b> | Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state: <ul style="list-style-type: none"> <li><code>CPACR.TRCDIS</code> behaves as RAO/WI, regardless of its actual value. See <a href="#">Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers on page G1-4422</a>. This behavior applies even if the <code>CPACR.TRCDIS</code> control is not implemented. See the referenced section for more information.</li> <li><code>HCPTR.TTA</code> behaves as RAO/WI, regardless of its actual value. See <a href="#">Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-4439</a>.</li> </ul> |
| <b>0</b> | There is no effect on accesses to <code>CPACR.TRCDIS</code> and <code>HCPTR.TTA</code> .   |

### Note

- System register accesses to the trace registers use the (coproc==0b1111) encoding space.
- `NSACR.NSTRCDIS` might be implemented as RAZ/WI. See the `NSACR` register description for more information.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- EL3 does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

## Enabling Non-secure access to SIMD and floating-point functionality

`NSACR.{cp11, cp10}` enable Non-secure access to the SIMD and floating-point registers, from all Privilege levels:

- |             |   |
|-------------|---|
| <b>0b11</b> | All accesses, from both Security states, are enabled.   |
| <b>0b00</b> | Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state: <ul style="list-style-type: none"> <li><code>CPACR.{cp11, cp10}</code> behave as RAZ/WI. See <a href="#">Enabling PL0 and PL1 accesses to the SIMD and floating-point registers on page G1-4423</a>.</li> <li><code>HCPTR.{TCP11, TCP10}</code> behave as RAO/WI. See <a href="#">General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-4437</a>.</li> </ul> |

### Note

Software must set `NSACR.cp11` and `NSACR.cp10` to the same value.

For more information about SIMD and floating-point support, see [Advanced SIMD and floating-point support on page G1-4412](#).

## Disabling Non-secure access to Advanced SIMD functionality

[NSACR.NSASEDIS](#) disables Non-secure accesses to the Advanced SIMD functionality, from all Privilege levels:

- 1** Non-secure state accesses are disabled. Secure accesses are enabled. If the PE is in Non-secure state:
- [CPACR.ASEDIS](#) behaves as RAO/WI. See *Disabling PL0 and PL1 execution of Advanced SIMD instructions* on page G1-4424.
  - [HCPTR.TASE](#) behaves as RAO/WI. See *Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality* on page G1-4438.
- These behaviors apply even if one or both of the [CPACR.ASEDIS](#) and [HCPTR.TASE](#) controls is not implemented. See the referenced sections for more information.
- 0** There is no effect on [CPACR.ASEDIS](#) and [HCPTR.TASE](#).

## G1.20.5 Pseudocode description of configurable instruction enables, disables, and traps

The pseudocode function [AArch32.CheckITEnabled\(\)](#) checks whether the T32 IT instruction is enabled.

The pseudocode function [AArch32.CheckSETENDEnabled\(\)](#) checks whether the SETEND instruction is disabled.

The pseudocode function for [AArch32.CheckForSMCTrap\(\)](#) checks for traps on an SMC instruction.

The [AArch32.CheckForWfxTrap\(\)](#) pseudocode function checks for traps on WFE and WFI instructions:

### Pseudocode description of enabling SIMD and floating-point functionality

The [AArch32.CheckAdvSIMDorFPEEnabled\(\)](#) and [AArch32.CheckFPAdvSIMDTrap\(\)](#) pseudocode functions take appropriate action if an SIMD or floating-point instruction is used when the SIMD and floating-point functionality is not enabled or is trapped.

The [CheckAdvSIMDorVFPEEnabled\(\)](#), [CheckAdvSIMDEnabled\(\)](#), and [CheckVFPEEnabled\(\)](#) wrapper functions support the [AArch32.CheckAdvSIMDorFPEEnabled\(\)](#) and [AArch32.CheckFPAdvSIMDTrap\(\)](#) functions.

The [AArch32.CheckAdvSIMDorFPEEnabled\(\)](#), [AArch32.CheckFPAdvSIMDTrap\(\)](#), [CheckAdvSIMDorVFPEEnabled\(\)](#), [CheckAdvSIMDEnabled\(\)](#), and [CheckVFPEEnabled\(\)](#) functions are described in [Chapter J1 ARMv8 Pseudocode](#).

# Chapter G2

## AArch32 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch32 self-hosted debug exception model. It is organized as follows:

### Introductory information

- [About self-hosted debug on page G2-4454.](#)
- [The debug exception enable controls on page G2-4458.](#)

### The debug Exception model

- [Routing debug exceptions on page G2-4459.](#)
- [Enabling debug exceptions from the current Privilege level and Security state on page G2-4461.](#)
- [The effect of powerdown on debug exceptions on page G2-4463.](#)
- [Summary of permitted routing and enabling of debug exceptions on page G2-4464.](#)
- [Pseudocode description of debug exceptions on page G2-4466.](#)

### The debug exceptions

- [Breakpoint Instruction exceptions on page G2-4467.](#)
- [Breakpoint exceptions on page G2-4470.](#)
- [Watchpoint exceptions on page G2-4496.](#)
- [Vector Catch exceptions on page G2-4510.](#)

### Synchronization requirements

The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a [Context synchronization event](#) guarantees the effects of the changes:

- [Synchronization and debug exceptions on page G2-4518.](#)

## G2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of *debug exceptions*, that are taken using the exception model described in:

- [Chapter D1 The AArch64 System Level Programmers' Model](#), if the exception is taken to AArch64 state.
- [Chapter G1 The AArch32 System Level Programmers' Model](#), if the exception is taken to AArch32 state.

This section introduces some terms used in describing self-hosted debug, and then introduces the debug exceptions. See:

- [Definition of a debugger in the context of self-hosted debug](#).
- [Context ID and Process ID](#).

### G2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, *debugger* means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

### G2.1.2 Context ID and Process ID

In AArch32 state, the [CONTEXTIDR](#) identifies the current *Context ID*, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

When using the Long-descriptor translation table format, the [CONTEXTIDR](#) has a single field, PROCID, that is defined as the *Process Identifier* (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical when using this translation table format.

When using the Short-descriptor translation table format:

- [CONTEXTIDR](#)[31:0] defines the Context ID, that is used for breakpoint and watchpoint matching.
- [CONTEXTIDR](#)[31:8] defines the Process ID.
- [CONTEXTIDR](#)[7:0] define the ASID. See [Global and process-specific translation table entries on page G4-4628](#). This means that, when using the Short-descriptor translation table format, the ASID is always bits[7:0] of the Context ID.

### G2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions. The debug exceptions that can be generated in an AArch32 stage 1 translation regime are:

- [Breakpoint Instruction exceptions on page G2-4455](#).
- [Breakpoint exceptions on page G2-4455](#), generated by hardware breakpoints.
- [Watchpoint exceptions on page G2-4456](#), generated by hardware watchpoints.
- [Vector Catch exceptions on page G2-4456](#).

#### ———— Note ————

In addition, *Software Step exceptions* can be generated in stage 1 of an AArch32 translation regime. However, these are always taken to AArch64 state. [Software Step exceptions on page D2-1908](#) describes this.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.

See [Enabling debug exceptions from the current Privilege level and Security state](#) on page G2-4461.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

2. A debugger has enabled that particular debug exception.

All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the [DBGDSCRExt](#). See [The debug exception enable controls](#) on page G2-4458.

#### ———— **Note** ————

If *halting is allowed* and [EDSCR.HDE](#) is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see [Halting allowed and halting prohibited](#) on page H2-5435.

When a debug exception is taken to an Exception level that is using AArch32:

- If the debug exception is a Watchpoint exception, it is taken as a Data Abort exception.
- Otherwise, it is taken as a Prefetch Abort exception.

The following list summarizes each of the debug exceptions:

#### **Breakpoint Instruction exceptions**

*Breakpoint instructions* generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A32 and T32 instruction sets is BKPT #<immediate>. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

##### **PE behavior**

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Privilege level and AArch32 mode.
- The current Security state.

For more information, see [Breakpoint Instruction exceptions](#) on page G2-4467.

#### **Breakpoint exceptions**

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address 0x1000 is committed for execution.

The ARMv8-A architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch32 translation regime:

- Address:
  - Address Match.
  - Address Mismatch.

Comparisons are made with the virtual address of each instruction in the program flow.
- Context:
  - Context ID Match. Matches with the Context ID value held in the [CONTEXTIDR](#).
  - VMID Match. Matches with the VMID value held in the [VTTBR](#).
  - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match or mismatch occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

#### PE behavior

If halting is allowed and `EDSCR.HDE` is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See [Chapter H2 Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see [Breakpoint exceptions on page G2-4470](#).

#### Watchpoint exceptions

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range `0x1000 - 0x101F`.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

#### PE behavior

If halting is allowed and `EDSCR.HDE` is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See [Chapter H2 Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see [Watchpoint exceptions on page G2-4496](#).

#### Vector Catch exceptions

These are used to trap exceptions. The ARMv8-A architecture provides two forms of vector catch, *address-matching* and *exception-trapping*. Only one form can be implemented.

Whichever form is implemented, a debugger must enable Vector Catch exceptions for one or more exception vectors by programming the `DBGVCR`. Generation of Vector Catch exceptions is then as follows:

- For the address-matching form, a Vector Catch exception is generated whenever the virtual address of an instruction matches a vector that Vector Catch exceptions are enabled for.
- For the Exception-trapping form, a Vector Catch exception is generated as part of exception entry for exception types that correspond to vectors that Vector Catch exceptions are enabled for.

#### PE behavior

If debug exceptions are:

- Enabled, Vector Catch exceptions can be generated.
- Disabled, vector catch is ignored.

For more information, see [Vector Catch exceptions on page G2-4510](#).

[Table G2-1 on page G2-4457](#) summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

**Table G2-1 PE behavior and pseudocode for each of the debug exceptions**

Debug exception	PE behavior if debug exceptions are:		Pseudocode
	Enabled	Disabled	
Breakpoint Instruction exception	Takes Prefetch Abort exception	Takes Prefetch Abort exception	<a href="#">AArch32.SoftwareBreakpoint()</a>
Breakpoint exception	Takes Prefetch Abort exception <sup>a</sup>	Ignored	See <i>Pseudocode description of Breakpoint exceptions taken from AArch32 state</i> on page G2-4494
Watchpoint exception	Takes Data Abort exception <sup>a</sup>	Ignored	See <i>Pseudocode description of Watchpoint exceptions taken from AArch32 state</i> on page G2-4509
Vector Catch exception	Takes Prefetch Abort exception	Ignored	See <i>Pseudocode description of Vector Catch exceptions</i> on page G2-4517

- a. If halting is allowed and [EDSCR.HDE](#) is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See [Chapter H2 Debug State](#).

## G2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

### Breakpoint Instruction exceptions

None. Breakpoint Instruction exceptions are always enabled.

### Breakpoint exceptions

[DBGDSCRExt](#).MDBGen, plus an enable control for each breakpoint, [DBGBCR<n>](#).E.

### Watchpoint exceptions

[DBGDSCRExt](#).MDBGen, plus an enable control for each watchpoint, [DBGWCR<n>](#).E.

### Vector Catch exceptions

[DBGDSCRExt](#).MDBGen.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See [Enabling debug exceptions from the current Privilege level and Security state on page G2-4461](#).

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

## G2.3 Routing debug exceptions

Debug exceptions are usually routed to Abort mode. However, if EL2 is implemented, the routing of debug exceptions taken from Non-secure state depends on the *Effective values* of **HDCR.TDE** and **HCR.TGE**:

**If the *Effective value* of {**HDCR.TDE**, **HCR.TGE**} is not {0, 0}**

Debug exceptions taken from Non-secure state are routed to Hyp mode.

**Otherwise**

In Non-secure state debug exceptions behave as follows:

- Debug exceptions taken from Non-secure EL1 and Non-secure EL0 are routed to Non-secure Abort mode.
- Breakpoint Instruction exceptions taken from Hyp mode are routed to Hyp mode.
- All other debug exceptions are disabled from Hyp mode.

———— **Note** ————

If EL2 is not implemented, the *Effective value* of **HCR.TGE** is 0 and the *Effective value* of **HDCR.TDE** is 0.

**Table G2-2**, **Table G2-3**, and **Table G2-4** show the routing of debug exceptions taken from an Exception level that is using AArch32 to an Exception level that is using AArch32. In these tables:

**TDE** Means the logical OR of **HDCR.TDE** and **HCR.TGE**.

**(Hyp mode)** Means:

- All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Privilege level.
- Breakpoint Instruction exceptions taken from this Privilege level are taken to Hyp mode.

**Table G2-2 Routing when both EL3 and EL2 are implemented**

TDE	Target AArch32 mode when executing in:			
	Non-secure:			Secure state
	PL0	PL1	PL2	
0	Non-secure Abort mode	Non-secure Abort mode	(Hyp mode)	Secure Abort mode
1	Hyp mode	Hyp mode	(Hyp mode)	Secure Abort mode

**Table G2-3 Routing when EL3 is implemented and EL2 is not implemented**

Target AArch32 mode when executing in:	
Non-secure state	Secure state
Non-secure Abort mode	Secure Abort mode

**Table G2-4 Routing when EL3 is not implemented and EL2 is implemented**

TDE	Target AArch32 mode when executing in Non-secure:		
	PL0	PL1	PL2
0	Non-secure Abort mode	Non-secure Abort mode	(Hyp mode)
1	Hyp mode	Hyp mode	(Hyp mode)

### G2.3.1 Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level. `DebugTargetFrom()` returns the debug target Exception level for the specified Security state.

## G2.4 Enabling debug exceptions from the current Privilege level and Security state

A debug exception can only be taken if all of the following are true:

- The OS lock is unlocked.
- `DoubleLockStatus() == FALSE`.
- The debug exception is enabled from the current Privilege level.
- The debug exception is enabled from the current Security state.

Table G2-5 shows when debug exceptions are enabled from the current Privilege level.

**Table G2-5 Whether debug exceptions are enabled from the current Privilege level**

Current Privilege level	Breakpoint Instruction exceptions	All other debug exceptions
PL2	Enabled	Disabled
PL1	Enabled	Enabled
PL0		

Table G2-6 shows when debug exceptions are enabled from the current Security state.

**Table G2-6 Whether debug exceptions are enabled from the current Security state**

Current Security state	Breakpoint Instruction exceptions	All other debug exceptions
Non-secure	Enabled	Enabled from PL1 and PL0 only.
Secure	Enabled	Depends on <a href="#">SDCR.SPD</a> and <a href="#">SDER.SUIDEN</a> . See <a href="#">Disabling debug exceptions from Secure state</a> .

### G2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can enable or disable all debug exceptions taken from Secure PL1 other than Breakpoint Instruction exceptions, by using one of:

- The *Secure Privileged Debug* field, [SDCR.SPD](#), if EL3 is using AArch32.
- The *AArch32 Secure Privileged Debug* field, [MDCR\\_EL3.SPD32](#), if EL3 is using AArch64.

If debug exceptions are disabled from Secure PL1, software executing at Secure PL1 can set the *Secure User Invasive Debug Enable* bit, [SDER.SUIDEN](#), to 1 to enable all debug exceptions taken from Secure PL0 other than Breakpoint Instruction exceptions.

#### ———— Note ————

Breakpoint Instruction exceptions are always enabled.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

#### ———— Note ————

If the boot software that is executed when reset is deasserted programs SUIDEN and SPD so that all debug exceptions are disabled from Secure state, software operating at EL3 never has to switch any of the debug registers between the Security states.

## G2.4.2 Pseudocode description of enabling debug exceptions

[AArch64.GenerateDebugExceptions\(\)](#) determines whether debug exceptions are enabled from the current Exception level and Security state. [AArch64.GenerateDebugExceptionsFrom\(\)](#) determines whether debug exceptions are enabled from the specified Exception level and Security state.

## G2.5 The effect of powerdown on debug exceptions

*Debug OS Save and Restore sequences on page H6-5541* describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and `DoubleLockStatus() == FALSE`.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.

## G2.6 Summary of permitted routing and enabling of debug exceptions

Behavior is as follows:

### Breakpoint Instruction exceptions

These are always enabled, regardless of the current Privilege level and Security state. [Table G2-7](#) shows the routing of these. In the table, n/a means not applicable.

**Table G2-7 Routing of Breakpoint Instruction exceptions**

Current Security state	HDCR.TDE <sup>a</sup> :	Target when enabled from:		
		PL0	PL1	PL2
Secure	X	Secure Abort mode <sup>b</sup>	Secure Abort mode <sup>b</sup>	n/a
Non-secure	0	Non-secure Abort mode	Non-secure Abort mode	Hyp mode
	1	Hyp mode	Hyp mode	Hyp mode

- If EL2 is not implemented, behavior is as if the value of this bit is 0. Otherwise, if the value of [HCR.TGE](#) is 1, [HDCR.TDE](#) is treated as being 1 other than for a direct read of [HDCR](#).
- If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1.

### All other debug exceptions

The enabling and permitted routing is controlled by all of the following:

- [SDCR.SPD](#).
- [SDER.SUIDEN](#).
- [HDCR.TDE](#).
- The IMPLEMENTATION DEFINED authentication interface.

[Table G2-8](#) shows the valid combinations of the values of [SDCR.SPD](#), [SDER.SUIDEN](#), [HDCR.TDE](#), and, in the *Auth* column, the input from the IMPLEMENTATION DEFINED authentication interface described by the pseudocode function

[AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled\(\)](#). For each combination, the table shows where debug exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

**Table G2-8 Breakpoint, Watchpoint, and Vector Catch exceptions**

Debug state	Lock <sup>a</sup>	Current Security state	SPD <sup>b</sup>	Auth <sup>c</sup>	SUIDEN	TDE <sup>d</sup>	Target AArch32 mode when enabled from:		
							PL0	PL1	PL2
Yes	X	X	0bXX	X	X	X	-	-	-
No	TRUE	X	0bXX	X	X	X	-	-	-
No	FALSE	Secure	0b00	FALSE	0	X	-	-	n/a
No	FALSE	Secure	0b00	FALSE	1	X	Secure Abort mode <sup>e</sup>	-	n/a
No	FALSE	Secure	0b00	TRUE	X	X	Secure Abort mode <sup>e</sup>	Secure Abort mode <sup>e</sup>	n/a
No	FALSE	Secure	0b10	X	0	X	-	-	n/a

**Table G2-8 Breakpoint, Watchpoint, and Vector Catch exceptions (continued)**

Debug state	Lock <sup>a</sup>	Current Security state	SPD <sup>b</sup>	Auth <sup>c</sup>	SUIDEN	TDE <sup>d</sup>	Target AArch32 mode when enabled from:		
							PL0	PL1	PL2
No	FALSE	Secure	0b10	X	1	X	Secure Abort mode <sup>e</sup>	-	n/a
No	FALSE	Secure	0b11	X	X	X	Secure Abort mode <sup>e</sup>	Secure Abort mode <sup>e</sup>	n/a
No	FALSE	Non-secure	0bXX	X	X	0	Non-secure Abort mode	Non-secure Abort mode	-
No	FALSE	Non-secure	0bXX	X	X	1	Hyp mode	Hyp mode	-

- The value of (OSLSR\_EL1.OSLK == '1' || DoubleLockStatus()).
- If EL3 is not implemented, behavior is as if this is 0b11.
- See the text that introduces this table for an explanation of the [Auth](#) on page G2-4464 column. An entry of TRUE indicates that the authentication mechanism permits the debug exceptions to be taken to their default target PE mode.
- If HCR.TGE is 1, this bit is treated as being 1 other than for a direct read of HDCR. If EL2 is not implemented, behavior is as if TDE is 0.
- If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1

## G2.7 Pseudocode description of debug exceptions

`AArch32.DebugFault()` returns a `FaultRecord()` that indicates that a memory access has generated a debug exception.

The `AArch32.Abort()` function processes `FaultRecord()`, as described in *Abort exceptions* on page G3-4555, and generates:

- Data Abort exceptions for watchpoints.
- Prefetch Abort exceptions for all other debug exceptions.

## G2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch32 translation regime.

---

### Note

---

When the PE is executing in EL0 using AArch32 and EL1 is using AArch64, it is using the AArch64 EL1&0 translation regime. A T32 or A32 BKPT instruction executed at EL0 can generate a Breakpoint Instruction exception that is taken to an Exception level that is using AArch64. For more information about the handling of these exceptions, see [Breakpoint Instruction exceptions on page D2-1919](#).

---

It contains the following subsections:

- [About Breakpoint Instruction exceptions](#).
- [Breakpoint instruction in the A32 and T32 instruction sets](#).
- [BKPT instructions as the first instruction in an IT block on page G2-4468](#).
- [Exception syndrome information and preferred return address for a BKPT instruction on page G2-4468](#).
- [Pseudocode description of Breakpoint Instruction exceptions on page G2-4469](#).

### G2.8.1 About Breakpoint Instruction exceptions

A *breakpoint* is an event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

*Breakpoint Instruction exceptions*, that this section describes, are software breakpoints. [Breakpoint exceptions on page G2-4470](#) describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the *debug target Exception level*,  $EL_D$ , is using AArch64 or AArch32.

---

### Note

---

- $EL_D$  is the Exception level that debug exceptions are targeting. See [Enabling debug exceptions from the current Privilege level and Security state on page G2-4461](#).
  - Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See [Concurrent modification and execution of instructions on page B2-84](#).
- 

### G2.8.2 Breakpoint instruction in the A32 and T32 instruction sets

The breakpoint instruction, in both instruction sets, is:

- BKPT #<immediate>

For details of the instruction encoding, see [BKPT on page F5-3065](#).

#### About whether the BKPT instruction is conditional

In the T32 instruction set, BKPT instructions are always unconditional.

In the A32 instruction set:

- If the Condition code field is AL, the BKPT instruction is unconditional.

- If the Condition code field is anything other than AL, behavior is CONSTRAINED UNPREDICTABLE, and is one of the following:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP instruction.
  - The instruction is executed unconditionally.
  - The instruction is executed conditionally.

### G2.8.3 BKPT instructions as the first instruction in an IT block

If the first instruction in an IT block is a T32 BKPT instruction, then in an implementation that supports the ITD control, if ITD field that applies to the current Exception level is:

- |          |  |
|----------|--|
| <b>0</b> | The BKPT instruction generates a Breakpoint Instruction exception.   |
| <b>1</b> | The combination of IT instruction and BKPT instruction is UNDEFINED. Either the IT instruction or the BKPT instruction generates an Undefined Instruction exception. |

In such an implementation, to ensure consistent behavior when making the first instruction in one or more IT blocks a BKPT instruction, the debugger must replace the IT instruction.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

The ITD control fields are:

**HSCTLR.ITD** Applies to execution at EL2 when EL2 is using AArch32.

**SCTLR.ITD** Applies to execution at EL0 or EL1 when EL1 is using AArch32.

**SCTLR\_EL1.ITD**

Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

#### ———— Note ————

T32 BKPT instructions are always unconditional, even when they are inside an IT block. See:

- [Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality on page G1-4421.](#)
- [Disabling or enabling EL2 use of AArch32 deprecated functionality on page G1-4430.](#)

### G2.8.4 Exception syndrome information and preferred return address for a BKPT instruction

See the following:

- [Exception syndrome information for a Breakpoint Instruction exception.](#)
- [Preferred return address for a Breakpoint Instruction exception on page G2-4469.](#)

#### ———— Note ————

Usually, the term *exception syndrome* is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the [IFSR](#).

### Exception syndrome information for a Breakpoint Instruction exception

The PE takes a Breakpoint Instruction exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp Trap exception, if it is taken to PL2 because either **HCR.TGE** or **HDCR.TDE** is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

#### **PL1 Abort mode**

The PE sets all of the following:

- **DBGDSCRExt.MOE** to 0b0011, to indicate a Breakpoint Instruction exception.

- [IFSR.FS](#) to the code for a debug, 0b00010.
- The [IFAR](#) with an UNKNOWN value.

### PL2 Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, [HSR](#). See [Table G2-9](#).
- Sets [DBGDSCRext.MOE](#) to 0b0011, to indicate a Breakpoint Instruction exception.
- Sets the [HIFAR](#) to an UNKNOWN value.

**Table G2-9 Information recorded in the [HSR](#)**

<b>HSR field</b>	<b>Information recorded</b>
<i>Exception Class</i> , EC	The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, 0x20.
<i>Instruction Length</i> , IL	The PE sets this to: <ul style="list-style-type: none"> <li>• 0 for a T32 BKPT instruction.</li> <li>• 1 for an A32 BKPT instruction.</li> </ul>
<i>Instruction Specific Syndrome</i> , ISS	<b>ISS[24:10]</b> RES0. <b>ISS[9]</b> <i>External Abort type</i> (EA). The PE sets this to 0. <b>ISS[8:6]</b> RES0. <b>ISS[5:0]</b> <i>Instruction Fault Status Code</i> (IFSC). The PE sets this to the code for a debug exception, 0b100010.

### ———— Note ————

For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions on page G2-4459](#).

## Preferred return address for a Breakpoint Instruction exception

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

### G2.8.5 Pseudocode description of Breakpoint Instruction exceptions

[AArch32.SoftwareBreakpoint\(\)](#) generates a Prefetch Abort exception that is taken from AArch32 state.

## G2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:

- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:

- [About Breakpoint exceptions.](#)
- [Breakpoint types and linking of breakpoints on page G2-4471.](#)
- [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480.](#)
- [Breakpoint instruction address comparisons on page G2-4482.](#)
- [Breakpoint context comparisons on page G2-4487.](#)
- [Using breakpoints on page G2-4488.](#)

### G2.9.1 About Breakpoint exceptions

A *breakpoint* is an event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

*Breakpoint exceptions* are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in [Breakpoint Instruction exceptions on page G2-4467](#).

An implementation can include between 2-16 hardware breakpoints. [DBGDIDR.BRPs](#) shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, [DBGBCR<n>](#). This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, [DBGBVR<n>](#). This holds a value used for breakpoint matching, that is one of:
  - An instruction virtual address.
  - A Context ID.
- If EL2 is implemented, the *Breakpoint Extended Value Register*, [DBGBXVR<n>](#), that holds a VMID value used for breakpoint matching.

These registers are numbered, so that:

- [DBGBCR1](#), [DBGBVR1](#), and [DBGBXVR1](#) are for breakpoint number one.
- [DBGBCR2](#), [DBGBVR2](#), and [DBGBXVR2](#) are for breakpoint number two.
- ...
- ...
- [DBGBCR<n>](#), [DBGBVR<n>](#), and [DBGBXVR<n>](#) are for breakpoint number <n>.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, **DBGBCR**<n>.E, is 1.
- The conditions specified in the **DBGBCR**<n> are met.
- The comparisons with the values held in one or both of the **DBGBVR**<n> and **DBGXVR**<n>, as applicable, are successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its Condition code check.
- The instruction type.

If halting is allowed and **EDSCR**.HDE is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are

- Enabled, Breakpoint debug events generate Breakpoint exceptions
- Disabled, Breakpoint debug events are ignored.

#### ———— **Note** ————

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

*The debug exception enable controls on page G2-4458 describes the enable controls for Breakpoint debug events.*

## G2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match.
  - An instruction address mismatch.
  - A Context ID match, with the value held in the **CONTEXTIDR**.
  - A VMID match, with the value held in the **VTTBR**.
  - Both a Context ID match and a VMID match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match or an instruction address mismatch.

**DBGDIDR**.CTX\_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match or mismatch is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an *Unlinked breakpoint*.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a *Linked breakpoint*.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match or mismatch occurs. For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Linked Context ID Match breakpoint*.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* field for a breakpoint, `DBGBCR<n>.BT`, controls the breakpoint type and whether the breakpoint is enabled for linking. If `BT[0]` is 1, the breakpoint is enabled for linking.

Figure G2-1 shows all of the possible breakpoint types that stage 1 of an AArch32 translation regime supports, and their associated BT field values.

		Unlinked	Linked
Address breakpoints	Address Mismatch	BT == 0b0100 Unlinked Address Mismatch	BT == 0b0101 Linked Address Mismatch
	Address Match	BT == 0b0000 Unlinked Address Match	BT == 0b0001 Linked Address Match
Context breakpoints	Context ID Match	BT == 0b0010 Unlinked Context ID Match	BT == 0b0011 Linked Context ID Match
	VMID Match	BT == 0b1000 Unlinked VMID Match	BT == 0b1001 Linked VMID Match
	VMID and context ID Match	BT == 0b1010 Unlinked VMID and Context ID Match	BT == 0b1011 Linked VMID and Context ID Match

**Figure G2-1 Breakpoint types and their associated BT field values**

Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See [Specifying the halfword-aligned address that an Address breakpoint matches on on page G2-4482](#).

## Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGBCR<n>.LBN`, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  - `DBGBCR<n>.{SSC, HMC, PMC}` for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480](#).
  - `DBGBCR<n>.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See [Other usage constraints for Address breakpoints on page G2-4492](#).
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

### **Note**

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. [Watchpoint exceptions on page G2-4496](#) describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked Address Mismatch breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

[Figure G2-2 on page G2-4474](#) shows an example of permitted breakpoint and watchpoint linking.

**Figure G2-2 The role of linking in Breakpoint and Watchpoint exception generation**

In [Figure G2-2](#), each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

### Breakpoint types defined by DBGBCRn.BT

The following list provides more detail about each breakpoint type:

#### 0b0000, Unlinked Address Match breakpoint

Generation of a Breakpoint exception depends on both:

- [DBGBCR<n>.{SSC, HMC, PMC}](#). These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480](#).
- A successful address match, as described in [Breakpoint instruction address comparisons on page G2-4482](#).

[DBGBCR<n>.LBN](#) for this breakpoint is ignored.

#### 0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>**. {SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480](#).
- A successful address match defined by this breakpoint, as described in [Breakpoint instruction address comparisons on page G2-4482](#).
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

**DBGBCR<n>**.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

#### 0b0010, Unlinked Context ID Match breakpoint

BT = 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>**. {SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480](#).
- A successful Context ID match, as described in [Breakpoint context comparisons on page G2-4487](#).

The value of **DBGBVR<n>**[31:0] is compared with the current Context ID. **CONTEXTIDR\_EL2** holds the current Context ID when all of:

- The implementation includes the Virtualization Host Extensions.
- The PE is in Non-secure state.
- **HCR\_EL2**.E2H is set to 1.
- The PE is executing at EL0 and **HCR\_EL2**.TGE is 1, or PE is executing at EL2.

Otherwise, **CONTEXTIDR** holds the current Context ID.

**DBGBCR<n>**. {LBN, BAS} for this breakpoint are ignored

#### 0b0011, Linked Context ID Match breakpoint

BT = 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons on page G2-4482](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page G2-4487](#).
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page G2-4500](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page G2-4487](#).

The value of **DBGBVR<n>**[31:0] is compared with the current Context ID. **CONTEXTIDR\_EL2** holds the current Context ID when all of:

- The implementation includes the Virtualization Host Extensions.
- The PE is in Non-secure state.
- **HCR\_EL2**.E2H is set to 1.
- The PE is executing at EL0 and **HCR\_EL2**.TGE is 1, or PE is executing at EL2.

Otherwise, `CONTEXTIDR` holds the current Context ID.

`DBGBCR<n>.{LBN, SSC, HMC, BAS PMC}` for this breakpoint are ignored.

#### 0b0100, Unlinked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on both:

- `DBGBCR<n>.{SSC, HMC, PMC}`. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-4480.
- A successful address mismatch, as described in *Breakpoint instruction address comparisons* on page G2-4482.

`DBGBCR<n>.LBN` for this breakpoint is ignored.

#### 0b0101, Linked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on all of the following:

- `DBGBCR<n>.{SSC, HMC, PMC}`. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-4480.
- A successful address mismatch defined by this breakpoint, as described in *Breakpoint instruction address comparisons* on page G2-4482.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

`DBGBCR<n>.LBN` for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

#### 0b0110, Unlinked CONTEXTIDR\_EL1 Match

`BT == 0b0110` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- `DBGBCR<n>.{SSC, HMC, PMC}`. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page G2-4487.

The Context ID check is made against the value in `CONTEXTIDR_EL1`. The value of `DBGBCR<n>.ContextID` is compared with the Context ID value held in `CONTEXTIDR_EL1`.

`DBGBCR<n>.{LBN, BAS}` for this breakpoint are ignored.

#### 0b0111, Linked CONTEXTIDR\_EL1 Match

`BT == 0b0111` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons* on page G2-4482.
  - A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page G2-4487.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page G2-4500](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page G2-4487](#).

The Context ID check is made against the value in `CONTEXTIDR_EL1`. The value of `DBGBVR<n>.ContextID` is compared with the Context ID value held in `CONTEXTIDR_EL1.DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC}` for this breakpoint are ignored.

#### 0b1000, Unlinked VMID Match breakpoint

BT = 0b1000 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- `DBGBCR<n>.{SSC, HMC, PMC}`. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480](#).
- A successful VMID match, as described in [Breakpoint context comparisons on page G2-4487](#).

`DBGBCR<n>.{LBN, BAS}` for this breakpoint are ignored.

#### 0b1001, Linked VMID Match breakpoint

BT = 0b1001 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See [Breakpoint instruction address comparisons on page G2-4482](#).
  - A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page G2-4500](#).
  - A successful VMID match defined by this breakpoint, as described in [Breakpoint context comparisons on page G2-4487](#).

`DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC}` for this breakpoint are ignored.

#### 0b1010, Unlinked Context ID and VMID Match breakpoint

BT = 0b1010 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-matching breakpoints, generation of a Breakpoint exception depends on all of the following:

- `DBGBCR<n>.{SSC, HMC, PMC}`. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480](#).
- A successful Context ID match, as described in [Breakpoint context comparisons on page G2-4487](#).

- A successful VMID match.

The value of `DBGBVR<n>.ContextID` is compared with the current Context ID.

`CONTEXTIDR_EL2` holds the current Context ID when all of:

- The implementation includes [ARMv8.1-VHE](#).
- The PE is in Non-secure state.
- EL2 using AArch64 and `HCR_EL2.E2H` is set to 1.
- The PE is executing at EL0 and `HCR_EL2.TGE` is 1, or the PE is executing at EL2.

Otherwise, `CONTEXTIDR` holds the current Context ID.

[Breakpoint context comparisons on page G2-4487](#) describes the requirements for a successful Context ID match and a successful VMID match.

`DBGBCR<n>.{LBN, BAS}` for this breakpoint are ignored.

#### 0b1011, Linked Context ID and VMID Match breakpoint

`BT == 0b1011` is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-matching breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on all of the following:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons on page G2-4482](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page G2-4487](#).
  - A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page G2-4500](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page G2-4487](#).
  - A successful VMID match defined by this breakpoint.

The value of `DBGBVR<n>.ContextID` is compared with the current Context ID.

`CONTEXTIDR_EL2` holds the current Context ID when all of:

- The implementation includes [ARMv8.1-VHE](#).
- The PE is in Non-secure state.
- EL2 using AArch64 and `HCR_EL2.E2H` is set to 1.
- The PE is executing at EL0 and `HCR_EL2.TGE` is 1, or the PE is executing at EL2.

Otherwise, `CONTEXTIDR` holds the current Context ID.

[Breakpoint context comparisons on page G2-4487](#) describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

`DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC}` for this breakpoint are ignored.

#### 0b1100, Unlinked `CONTEXTIDR_EL2` Match

`BT == 0b1100` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>**. {SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful **CONTEXTIDR\_EL2** match, as described in *Breakpoint context comparisons* on page G2-4487.

The Context ID check is made against the value in **CONTEXTIDR\_EL2**. The value of check against **CONTEXTIDR\_EL2** means this breakpoint can be generated only if execution is in Non-secure state and EL2 is using AArch64.

**DBGBCR<n>**. {LBN, BAS} for this breakpoint are ignored.

#### 0b1101, Linked **CONTEXTIDR\_EL2** Match

BT == 0b1101 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include **ARMv8.1-VHE**.

For context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons* on page G2-4482.
  - A successful **CONTEXTIDR\_EL2** match, as described in *Breakpoint context comparisons* on page G2-4487.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons* on page G2-4500.
  - A successful **CONTEXTIDR\_EL2** match, as described in *Breakpoint context comparisons* on page G2-4487.

The Context ID check is made against the value in **CONTEXTIDR\_EL2**, regardless of the value of **HCR\_EL2.E2H**. The check against the **CONTEXTIDR\_EL2** means this breakpoint or watchpoint can be generated only if execution is in Non-secure state and EL2 is using AArch64.

**DBGBCR<n>**. {LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

#### 0b1110, Unlinked Full Context ID Match

BT == 0b1110 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include **ARMv8.1-VHE**.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>**. {SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in *Breakpoint context comparisons* on page G2-4487.

The Context ID check is made by checking the value of **DBGBVR<n>**.ContextID against the value in **CONTEXTIDR\_EL1** and the value of **DBGBXVR<n>**.ContextID against the value in **CONTEXTIDR\_EL2**. Both comparisons must match for the check to succeed.

- The check against the **CONTEXTIDR\_EL2** means this breakpoint can be generated only if execution is in Non-secure state and EL2 is using AArch64.

**DBGBCR<n>**. {LBN, BAS} for this breakpoint are ignored.

#### 0b1111, Linked Full Context ID Match

BT == 0b1111 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons](#) on page G2-4482.
  - A successful Context ID match, as described in [Breakpoint context comparisons](#) on page G2-4487.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons](#) on page G2-4500.
  - A successful Context ID match, as described in [Breakpoint context comparisons](#) on page G2-4487.

The Context ID check is made by checking the value of [DBGBVR<n>.ContextID](#) against the value in [CONTEXTIDR\\_EL1](#) and the value of [DBGBXVR<n>.ContextID](#) against the value in [CONTEXTIDR\\_EL2](#). Both comparisons must match for the check to succeed.

- The check against the [CONTEXTIDR\\_EL2](#) means this breakpoint or watchpoint can be generated only if execution is in Non-secure state and EL2 is using AArch64.

[DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC}](#) for this breakpoint are ignored.

#### ————— Note —————

See [Reserved \[DBGBCR<n>.BT\]\(#\) values](#) on page G2-4490 for the behavior of breakpoints programmed with reserved BT values.

### G2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at PL0 in Secure state.

[DBGBCR<n>.{SSC, HMC, PMC}](#) define the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

#### Security State Control, SSC

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

#### ————— Note —————

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

#### Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which AArch32 modes the breakpoint generates Breakpoint exceptions in.

[Table G2-10 on page G2-4481](#) shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Privilege levels breakpoints generate Breakpoint exceptions in.

In the table:

- Y or -** Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row:  
**Y** Can generate Breakpoint exceptions in AArch32 modes at that Privilege level.  
**-** Cannot generate Breakpoint exceptions in AArch32 modes at that Privilege level.
- Res** Means that the combination of HMC, SSC, and PMC is reserved. See [Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-4491](#).

**Table G2-10 Summary of breakpoint HMC, SSC, and PMC encodings**

HMC	SSC	PMC	Security state the breakpoint is programmed to match in	PL2 <sup>a</sup>	PL1	PL0	Implementation	
							No EL3	No EL2 and no EL3
0	00	00	Both	-	Y <sup>b</sup>	Y <sup>b</sup>	-	-
0	00	01		-	Y	-	-	-
0	00	10		-	-	Y	-	-
0	00	11		-	Y	Y	-	-
0	01	00	Non-secure	-	Y <sup>b</sup>	Y <sup>b</sup>	Res	Res
0	01	01		-	Y	-	Res	Res
0	01	10		-	-	Y	Res	Res
0	01	11		-	Y	Y	Res	Res
0	10	00	Secure	-	Y <sup>b</sup>	Y <sup>b</sup>	Res	Res
0	10	01		-	Y	-	Res	Res
0	10	10		-	-	Y	Res	Res
0	10	11		-	Y	Y	Res	Res
1	00	01	Both	Y	Y	-	-	Res
1	00	11		Y	Y	Y	-	Res
1	01	01	Non-secure	Y	Y	-	Res	Res
1	01	11		Y	Y	Y	Res	Res
1	10	01	Secure	-	Y	-	Res	Res
1	10	11		-	Y	Y	Res	Res
1	11	00	Non-secure	Y	-	-	-	Res if no EL2 <sup>c</sup>

- a. Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at PL2 using AArch32.
- b. Only in User, System and Supervisor modes.
- c. This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See [Reserved HMC, SSC, and PMC combinations on page G2-4491](#).

## G2.9.4 Breakpoint instruction address comparisons

Address comparisons are made for each instruction in the program flow. The following subsections describe the criteria for a successful address comparison, for:

- [Address Match breakpoints](#).
- [Address Mismatch breakpoints](#).

### Address Match breakpoints

An address match comparison is successful if both:

- Bits [31:2] of the current instruction virtual address are equal to [DBGBVR<n>](#)[31:2].
- The word or halfword selected by [DBGBCR<n>](#).BAS matches. That is, either:
  - [DBGBCR<n>](#).BAS is programmed with 0b0011 or 0b1111, and the instruction is at a word-aligned address.
  - [DBGBCR<n>](#).BAS is programmed with 0b1100, and the instruction is not at a word-aligned address.

See [Specifying the halfword-aligned address that an Address breakpoint matches on](#).

---

#### Note

[DBGBVR<n>](#)[1:0] are RES0 and are ignored.

---

### Address Mismatch breakpoints

An address mismatch comparison is successful if either:

- Bits [31:2] of the current instruction virtual address are not equal to [DBGBVR<n>](#)[31:2].
- The word or halfword selected by [DBGBCR<n>](#).BAS does not match. That is, either:
  - [DBGBCR<n>](#).BAS is programmed with 0b0011 or 0b1111, and the instruction is not at a word-aligned address.
  - [DBGBCR<n>](#).BAS is programmed with 0b1100, and the instruction is at a word-aligned address.

See [Specifying the halfword-aligned address that an Address breakpoint matches on](#).

---

#### Note

- [DBGBVR<n>](#)[1:0] are RES0 and are ignored.
  - Address Mismatch breakpoints can be used to single-step through code. See [Using an Address Mismatch breakpoint to single-step an instruction on page G2-4488](#).
- 

### Specifying the halfword-aligned address that an Address breakpoint matches on

For an Address breakpoint, a debugger can use the *Byte Address Selection* field, [DBGBCR<n>](#).BAS, so that the address comparison is successful on one of:

- The whole word starting at address [DBGBVR<n>](#)[31:2]:00.
- The halfword starting at address [DBGBVR<n>](#)[31:2]:00.
- The halfword starting at address (([DBGBVR<n>](#)[31:2]:00) + 2).

---

#### Note

The address programmed into the [DBGBVR<n>](#) must be word-aligned.

---

**DBGBCR<n>**.BAS can be used in both Address Match breakpoints and Address Mismatch breakpoints, as follows:

- For an Address Match breakpoint, **DBGBCR<n>**.BAS selects which halfword-aligned address the breakpoint must generate a Breakpoint exception for. This means that an address comparison is successful only if both of the following match:
  - The instruction address held in bits [31:2] of the **DBGBVR<n>**.
  - The halfword defined by the BAS field.
 That is, a successful address comparison = **DBGBVR<n>**[31:2] match AND BAS match.
- For an Address Mismatch breakpoint, **DBGBCR<n>**.BAS selects which halfword-aligned address the breakpoint must not generate a Breakpoint exception for. This means that an address comparison is successful if either or both of the following do not match:
  - The instruction address held in bits [31:2] of the **DBGBVR<n>**.
  - The halfword defined by the BAS field.
 That is, a successful address comparison = NOT (**DBGBVR<n>**[31:2] match AND BAS match).

The following subsections show the supported BAS values:

- Using the BAS field in Address Match breakpoints.*
- Using the BAS field in Address Mismatch breakpoints on page G2-4485.*

For Context breakpoints, **DBGBCR<n>**.BAS is RES1 and is ignored.

### **Using the BAS field in Address Match breakpoints**

The supported BAS values are:

- |               |   |
|---------------|---|
| <b>0b0000</b> | <p>This value is reserved. Behavior is a CONSTRAINED UNPREDICTABLE choice of:</p> <ul style="list-style-type: none"> <li>The breakpoint is disabled.</li> <li>The breakpoint behaves as if BAS is <b>0b0011</b>, <b>0b1100</b>, or <b>0b1111</b>.</li> </ul>  |
| <b>0b0011</b> | <p>The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:</p> <ul style="list-style-type: none"> <li>Bits [31:2] of the address equals <b>DBGBVR&lt;n&gt;</b>[31:2].</li> <li>Bits [1:0] of the address are <b>0b00</b>.</li> </ul> <p>This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:</p> <ul style="list-style-type: none"> <li>32-bit T32 instructions at word-aligned addresses.</li> <li>16-bit T32 instructions at word-aligned addresses.</li> <li>A32 instructions. These are always at word-aligned addresses.</li> </ul> <p>However, ARM recommends that a debugger uses this BAS value only for T32 instructions.</p> <p>It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((<b>DBGBVR&lt;n&gt;</b>[31:2]:00) - 2).</p> |
| <b>0b1100</b> | <p>The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:</p> <ul style="list-style-type: none"> <li>Bits [31:2] of the address equals <b>DBGBVR&lt;n&gt;</b>[31:2].</li> <li>Bits [1:0] of the address are <b>0b10</b>.</li> </ul> <p>This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for both of the following:</p> <ul style="list-style-type: none"> <li>32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.</li> <li>16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.</li> </ul> <p>It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction starting at a word-aligned address.</p>  |

0b1111 The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals `DBGBVR<n>[31:2]`.
- Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for A32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address  $((\text{DBGBVR}\langle n \rangle[31:2]:00) - 2)$ .

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address  $((\text{DBGBVR}\langle n \rangle[31:2]:00) + 2)$ .

All other BAS values are reserved. For these reserved other values, `DBGBCR<n>.BAS[3,1]` ignore writes and read the same values as `DBGBCR<n>[2,0]` respectively. This means that the smallest instruction size a debugger can program breakpoints to match on is a halfword.

Figure G2-3 on page G2-4485 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 2 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the halfword-aligned address  $((\text{DBGBVR}\langle n \rangle[31:2]:00) + 2)$ .
- Row 6 shows that a breakpoint with a BAS value of either 0b0011 or 0b1111 generates Breakpoint exceptions for A32 instructions. A32 instructions are always at word-aligned addresses.

In the figure:

**Yes** Means that the breakpoint generates a Breakpoint exception.

**No** Means that the breakpoint does not generate a Breakpoint exception.

**UNP** Means that it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See *Other usage constraints for Address breakpoints* on page G2-4492.

	Instruction set	Size	Location of instruction <sup>a</sup>								BAS[3:0]		
			-2	-1	0	+1	+2	+3	+4	+5	0b0011	0b1100	0b1111
Row 1	T32	16-bit									Yes	No	Yes
Row 2		16-bit									No	Yes	UNP
Row 3	T32	32-bit									UNP	No	UNP
Row 4		32-bit									Yes	UNP	Yes
Row 5		32-bit									No	Yes	UNP
Row 6	A32	32-bit									Yes	UNP	Yes

- a. 0 means the word-aligned address held in the DBGBVRn. The other locations are as follows:
- -2 means ((DBGBVRn[31:2]:00) - 2).
  - -1 means ((DBGBVRn[31:2]:00) - 1).
  - ...
  - ...
  - +5 means ((DBGBVRn[31:2]:00) + 5).

The solid areas show the location of the instruction.

**Figure G2-3 Summary of BAS field meanings for Address Match breakpoints**

#### Using the BAS field in Address Mismatch breakpoints

An Address Mismatch breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed to match.

The supported BAS values are:

**0b0000** The breakpoint ignores the address held in the DBGBVR<n> and generates Breakpoint exceptions for all instruction addresses.

**0b0011** The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for T32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) - 2).

**0b1100** The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are 0b10.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for either of the following:

- 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
- 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction at a word-aligned address.

0b1111 The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals `DBGBVR<n>[31:2]`.
- Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for A32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address  $((\text{DBGBVR}\langle n \rangle[31:2]:00) - 2)$ .

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address  $((\text{DBGBVR}\langle n \rangle[31:2]:00) + 2)$ .

All other BAS values are reserved. For these reserved other values, `DBGBCR<n>.BAS[3,1]` ignore writes and read the same values as `DBGBCR<n>[2,0]` respectively. This means that the smallest instruction size that a breakpoint can never generate a Breakpoint exception for is a halfword.

[Figure G2-4 on page G2-4487](#) shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 1 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the word-aligned address held in the `DBGBVR<n>`.
- Row 5 shows that a breakpoint with a BAS value of 0b0011 generates Breakpoint exceptions for 32-bit T32 instructions starting at the halfword-aligned address immediately after the word aligned address held in the `DBGBVR<n>`.

In the figure:

**Yes** Means that the breakpoint does generate a Breakpoint exception.

**No** Means that the breakpoint does not generate a Breakpoint exception.

**UNP** Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See [Other usage constraints for Address breakpoints on page G2-4492](#).

	Instruction set	Size	Location of instruction <sup>a</sup>								BAS[3:0]			
			-2	-1	0	+1	+2	+3	+4	+5	0b0000	0b0011	0b1100	0b1111
Row 1	T32	16-bit									Yes	No	Yes	No
Row 2		16-bit									Yes	Yes	No	UNP
Row 3	T32	32-bit									Yes	UNP	Yes	UNP
Row 4		32-bit									Yes	No	UNP	No
Row 5		32-bit									Yes	Yes	No	UNP
Row 6	A32	32-bit									Yes	No	UNP	No

a. 0 means the word-aligned address held in the DBGBVRn. The other locations are as follows:

- -2 means ((DBGBVRn[31:2]:00) - 2).
- -1 means ((DBGBVRn[31:2]:00) - 1).
- ...
- ...
- +5 means ((DBGBVRn[31:2]:00) + 5).

The solid areas show the location of the instruction.

**Figure G2-4 Summary of BAS field meanings for Address Mismatch breakpoints**

## G2.9.5 Breakpoint context comparisons

The breakpoint type defined by [DBGBCR<n>.BT](#) determines what context comparison is required, if any. [Table G2-11](#) shows the BT values that require a comparison, and the match required for the comparison to be successful.

**Table G2-11 Breakpoint context comparison tests**

<a href="#">DBGBCR&lt;n&gt;.BT</a>	Test required for successful context comparison
0b001x	When <a href="#">ARMv8.1-VHE</a> is not implemented, <a href="#">CONTEXTIDR</a> value matches <a href="#">DBGBVR&lt;n&gt;.ContextID</a> value
	When <a href="#">ARMv8.1-VHE</a> is implemented, <a href="#">CONTEXTIDR_EL2</a> value matches <a href="#">DBGBXVR&lt;n&gt;.ContextID</a> value
0b011x	<a href="#">CONTEXTIDR_EL1</a> value matches <a href="#">DBGBVR&lt;n&gt;.ContextID</a> value
0b100x	<a href="#">VTTBR.VMID</a> value matches <a href="#">DBGBVR&lt;n&gt;.VMID</a> value
0b101x	When <a href="#">ARMv8.1-VHE</a> is not implemented, <a href="#">CONTEXTIDR</a> value matches <a href="#">DBGBVR&lt;n&gt;.ContextID</a> value and <a href="#">VTTBR.VMID</a> value matches <a href="#">DBGBVR&lt;n&gt;.VMID</a> value
	When <a href="#">ARMv8.1-VHE</a> is implemented, <a href="#">CONTEXTIDR_EL2</a> value matches <a href="#">DBGBXVR&lt;n&gt;.ContextID</a> value and <a href="#">VTTBR.VMID</a> value matches <a href="#">DBGBVR&lt;n&gt;.VMID</a> value
0b110x	<a href="#">CONTEXTIDR_EL2</a> value matches <a href="#">DBGBXVR&lt;n&gt;.ContextID</a> value
0b111x	<a href="#">CONTEXTIDR_EL1</a> value matches <a href="#">DBGBVR&lt;n&gt;.ContextID</a> value and <a href="#">CONTEXTIDR_EL2</a> value matches <a href="#">DBGBXVR&lt;n&gt;.ContextID</a> value

No context comparison is required for other valid [DBGBCR<n>.BT](#) values.

In ARMv8.0 only, context breakpoints do not generate Breakpoint exceptions when execution is at EL2.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of [CONTEXTIDR\\_EL1](#) and any of:
  - The PE is executing at EL3 using AArch64.

- The PE is executing at EL2.
- The Virtualization Host Extensions are implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and `HCR_EL2.{E2H, TGE} == {1, 1}`.
- The comparison uses the value of `CONTEXTIDR_EL2` and any of:
  - The Virtualization Host Extensions are not implemented.
  - The PE is in Secure state.
  - EL2 is using AArch32.
- The comparison uses the current VMID value and any of:
  - EL2 is not implemented.
  - The PE is in Secure state.
  - The PE is executing at EL2.
  - The Virtualization Host Extensions are implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and `HCR_EL2.{E2H, TGE} == {1, 1}`.

The following Context breakpoint types do not generate Breakpoint exceptions in Secure state:

- VMID Match breakpoints.
- VMID and Context ID Match breakpoints.

———— **Note** ————

- For all Context breakpoints, `DBGBCR<n>.BAS` is RES1 and is ignored.
- For Linked Context breakpoints, `DBGBCR<n>.{LBN, SSC, HMC, PMC}` are RES0 and are ignored.

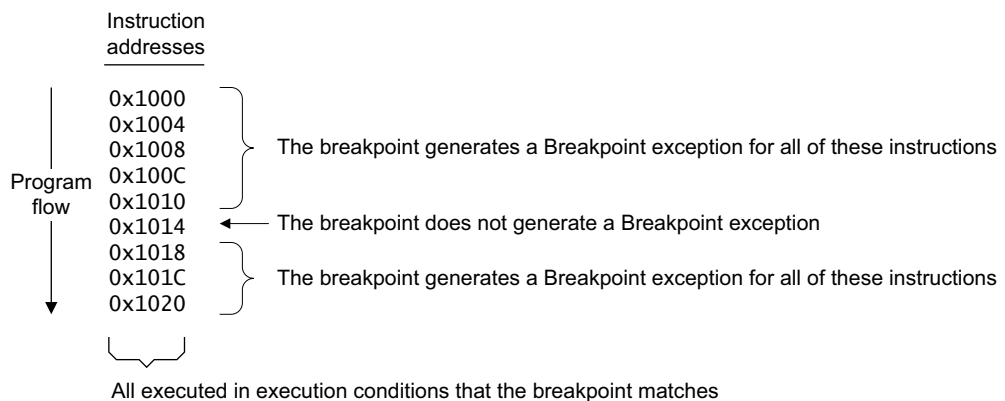

## G2.9.6 Using breakpoints

This section contains the following:

- [Using an Address Mismatch breakpoint to single-step an instruction.](#)
- [ITD control effects on address breakpoints on the first instruction in an IT block on page G2-4489.](#)
- [Breakpoint usage constraints on page G2-4490.](#)

### Using an Address Mismatch breakpoint to single-step an instruction

In execution conditions that an Address Mismatch breakpoint matches, defined by `DBGBCR<n>.{LBN, SSC, PMC}`, the breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed with. [Figure G2-5](#) shows an example of Address Mismatch breakpoint operation, for an Address Mismatch breakpoint programmed with address 0x1014.

**Figure G2-5 Operation of an Address Mismatch breakpoint**

This means that an Address Mismatch breakpoint can be used to single-step an instruction.

In the example shown in [Figure G2-5 on page G2-4488](#):

- If the target of a branch is an instruction other than the instruction at address 0x1014, the breakpoint generates a Breakpoint exception when the instruction is committed for execution.
- If the target of a branch is the instruction at address 0x1014, the PE executes the instruction at 0x1014 and the breakpoint does not generate a Breakpoint exception until the instruction at address 0x1018 is committed for execution. The instruction at address 0x1014 is therefore single-stepped.

However, if the instruction at 0x1014 generates a synchronous exception, or if the PE takes an asynchronous exception while the instruction is being stepped, the breakpoint is evaluated again after taking the exception. This means that behavior is as follows:

- If the exception handler executes in execution conditions that the breakpoint matches, the breakpoint generates a Breakpoint exception for the exception vector, because the exception vector is not address 0x1014. This means that software execution steps into the exception.
- If the exception handler executes in execution conditions that the breakpoint does not match, the breakpoint does not generate any Breakpoint exceptions after the PE has taken the exception, until the exception handler completes and executes an exception return instruction. The effect is to step over the exception. Whether the instruction is stepped again depends on whether the target of the exception return instruction is the instruction at 0x1014 or the instruction at 0x1018.

If the instruction at 0x1014 is single-stepped and branches to itself, it is **CONSTRAINED UNPREDICTABLE** whether the breakpoint generates a Breakpoint exception after the PE has executed the branch.

This means that an instruction is only single-stepped if it is the target of a branch instruction and its address matches the address the breakpoint is programmed for. In the example shown in [Figure G2-5 on page G2-4488](#), this is 0x1014.

Usually this branch instruction is an exception return instruction that changes PE mode, branching from a PE mode in which the breakpoint does not generate a Breakpoint exception. A branch instruction that does not change PE mode would itself generate a Breakpoint exception. However, it might be a branch-to-self instruction as described above.

Because Address Mismatch breakpoints can single-step instructions, the behavior of an address mismatch Breakpoint exception is similar to the behavior of an AArch64 Software Step exception.

#### ———— **Note** ————

- The example shown in [Figure G2-5 on page G2-4488](#) assumes an A32 instruction. The same behavior applies for both 32-bit and 16-bit T32 instructions.
- Software Step exceptions are the highest priority synchronous exception. Breakpoint exceptions are lower priority. See [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#).

## **ITD control effects on address breakpoints on the first instruction in an IT block**

In an implementation that supports the ITD control, if the value of the ITD field that applies to the current Exception level is 1, all of the following are true:

- An IT instruction can only be used to apply to one 16-bit T32 instruction.
- Only certain combinations of an IT instruction and second single 16-bit T32 instruction are permitted.
- For a permitted combination, it is **IMPLEMENTATION DEFINED** whether the implementation treats the combination as:
  - A pair of 16-bit instructions.
  - One 32-bit instruction.

If the implementation treats the combination as one 32-bit instruction, then as described in [Other usage constraints for Address breakpoints on page G2-4492](#), an Address breakpoint might not generate a Breakpoint exception for an address match only on the second halfword of the instruction.

For this reason, if the ITD bit associated with the current Exception level is 1, ARM recommends that a debugger that wants to program a breakpoint to match on the second T32 instruction programs it to match on the IT instruction instead.

However, if returning from an exception whose preferred return address is the address of the second T32 instruction, then because the debugger is aware that the implementation has treated the combination as a pair of 16-bit instructions, the debugger is permitted to program the breakpoint to match on the second T32 instruction.

The ITD control fields are:

**HSCTLR.ITD** Applies to execution at EL2 when EL2 is using AArch32.

**SCTLR.ITD** Applies to execution at EL0 or EL1 when EL1 is using AArch32.

**SCTLR\_EL1.ITD**

Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0, and therefore the information in this section does not apply to such an implementation.

#### ———— Note ————

Programming the breakpoint to match on the second T32 instruction might be necessary when using an Address Mismatch breakpoint for single stepping.

## Breakpoint usage constraints

See the following sections:

- [Reserved DBGBCR<n>.BT values.](#)
- [Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-4491.](#)
- [Reserved DBGBCR<n>.BAS values on page G2-4491.](#)
- [Reserved DBGBCR<n>.LBN values on page G2-4492.](#)
- [Other usage constraints for Address breakpoints on page G2-4492.](#)
- [Other usage constraints for Context breakpoints on page G2-4493.](#)

### Reserved DBGBCR<n>.BT values

Table G2-12 shows when particular DBGBCR<n>.BT values are reserved.

**Table G2-12 Reserved BT values**

BT value	Breakpoint type	Reserved
0b001x	Context ID Match	For non context-aware breakpoints
0b010x	Address Mismatch	If <a href="#">EDSCR.HDE</a> is 1 and halting is allowed
0b011x	CONTEXTIDR_EL1 Match	When <a href="#">ARMv8.1-VHE</a> is not implemented and breakpoints are not context-aware
0b100x	VMID Match	For non context-aware breakpoints, or if EL2 is not implemented
0b101x	Context ID and VMID Match	
0b110x	CONTEXTIDR_EL2 Match	When <a href="#">ARMv8.1-VHE</a> is not implemented and breakpoints are not context-aware
0b111x	Full Context ID Match	

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.

- Programmed with a BT value that is not reserved, other than for a direct or external read of [DBGBCR<n>](#).
- For a direct or external read of [DBGBCR<n>](#), if the reserved BT value:
  - Has no function for any execution conditions, the value read back is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

### Reserved [DBGBCR<n>](#).{SSC, HMC, PMC} values

[Table G2-13](#) shows when particular combinations of [DBGBCR<n>](#).{SSC, HMC, PMC} are reserved in stage 1 of an AArch32 translation regime.

**Table G2-13 Reserved HMC, SSC, and PMC combinations**

HMC, SSC, and PMC combination	Reserved
All combinations with SSC set to 0b01 or 0b10.	When EL3 is not implemented and EL2 is implemented.
Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00	When both of EL2 and EL3 are not implemented
The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00	When EL2 is not implemented
Combinations not included in <a href="#">Table G2-10 on page G2-4481</a>	Always

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.
  - A direct or external read of [DBGBCR<n>](#).{SSC, HMC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.
- If the reserved combination does not have a function for other execution conditions:
  - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct or external read of [DBGBCR<n>](#).{SSC, HMC, PMC} returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.
- A direct or external read of [DBGBCR<n>](#).{SSC, HMC, PMC} returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

### Reserved [DBGBCR<n>](#).BAS values

#### For all Context breakpoints

[DBGBCR<n>](#).BAS is RES1 and is ignored.

#### For all Address breakpoints

The supported values of the BAS field for the Address Match and Address Mismatch breakpoints are shown in [Specifying the halfword-aligned address that an Address breakpoint matches on on page G2-4482](#).

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BAS value that is not reserved, other than for a direct or external read of [DBGBCR<n>](#).
- A direct or external read of [DBGBCR<n>](#).BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

#### Reserved [DBGBCR<n>](#).LBN values

##### For all Context breakpoints

[DBGBCR<n>](#).LBN reads UNKNOWN and its value is ignored.

##### For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any [DBGBCR<n>](#).LBN value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of [DBGBCR<n>](#).LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint that links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

##### For Unlinked Address breakpoints

[DBGBCR<n>](#).LBN reads UNKNOWN and its value is ignored.

#### Other usage constraints for Address breakpoints

##### For all Address breakpoints

- [DBGBVR<n>](#)[1:0] are RES0 and are ignored.
- The [DBGBXVR<n>](#) is ignored.

##### For Address Match breakpoints

- For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
- If [DBGBCR<n>](#).BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address (([DBGBVR<n>](#)[31:2]:00) + 2). For T32 instructions, ARM recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

##### For Address Mismatch breakpoints

The constraints are the same as those described in [For Address Match breakpoints](#), except that if two Address Mismatch breakpoints are programmed to match in the same Exception level and Security state, it is CONSTRAINED UNPREDICTABLE whether or not the instruction is stepped or a Breakpoint debug even is generated.

### Other usage constraints for Context breakpoints

#### For all Context breakpoints

Any bits of [DBGBVR<n>](#) and [DBGBXVR<n>](#) that are not used to specify Context ID or VMID are RES0 and are ignored.

---

#### Note

This means that for Context ID Match breakpoints, the [DBGBXVR<n>](#) is RES0 and is ignored, and for VMID Match breakpoints, the [DBGBVR<n>](#) is RES0 and is ignored.

---

#### For Linked Context breakpoints

If no Linked Address breakpoints or Linked Watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

## G2.9.7 Exception syndrome information and preferred return address for a Breakpoint exception

See the following:

- [Exception syndrome information for a Breakpoint exception.](#)
- [Preferred return address for a Breakpoint exception on page G2-4494.](#)

---

#### Note

Usually, the term *exception syndrome* is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the [IFSR](#).

---

### Exception syndrome information for a Breakpoint exception

The PE takes a Breakpoint exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because [HCR.TGE](#) or [HDCR.TDE](#) is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

#### Abort mode

The PE sets all of the following:

- [DBGDSCRext.MOE](#) to 0b0001, to indicate a Breakpoint exception.
- [IFSR.FS](#) to the code for a debug exception, 0b00010.
- The [IFAR](#) with an UNKNOWN value.

## Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, [HSR](#). See [Table G2-14](#).
- Sets [DBGDSCRext](#).MOE to 0b0001, to indicate a Breakpoint exception.
- Sets the [HIFAR](#) to an UNKNOWN value.

**Table G2-14 Information recorded in the [HSR](#)**

HSR field	Information recorded
<i>Exception Class</i> , EC	The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, 0x20.
<i>Instruction Length</i> , IL	The PE sets this to 1.
<i>Instruction Specific Syndrome</i> , ISS	<b>ISS[24:10]</b> RES0. <b>ISS[9]</b> <i>External Abort type</i> (EA). The PE sets this to 0. <b>ISS[8:6]</b> RES0. <b>ISS[5:0]</b> <i>Instruction Fault Status Code</i> (IFSC). The PE sets this to the code for a debug exception, 0b100010.

### Note

For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions on page G2-4459](#).

## Preferred return address for a Breakpoint exception

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

## G2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch32 state

[AArch32.BreakpointValueMatch\(\)](#) returns a pair of results:

- A result for Address Match and Context breakpoints.
- A result for Address Mismatch breakpoints.

[AArch32.StateMatch\(\)](#) tests the values in [DBGBCR<n>](#). {SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

[AArch32.BreakpointMatch\(\)](#) tests a committed instruction against all breakpoints.

[AArch32.CheckBreakpoint\(\)](#) generates a [FaultRecord](#). A Breakpoint exception is taken if all of the following are true:

- [DBGDSCRext](#).MDBGen is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Privilege level and Security state on page G2-4461](#).
- All of the conditions required for Breakpoint exception generation are met. See [About Breakpoint exceptions on page G2-4470](#).

### Note

[AArch32.CheckBreakpoint\(\)](#) might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The `AArch32.Abort()` function processes the `FaultRecord` object returned by `AArch32.CheckBreakpoint()`, as described in *Abort exceptions* on page G3-4555. When a Breakpoint exception is taken to AArch32 state, the `AArch32.Abort()` function generates a Prefetch Abort exception.

## G2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:

- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:

- [About Watchpoint exceptions.](#)
- [Watchpoint types and linking of watchpoints on page G2-4498.](#)
- [Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-4499.](#)
- [Watchpoint data address comparisons on page G2-4500.](#)
- [Determining the memory location that caused a Watchpoint exception on page G2-4504.](#)
- [Watchpoint behavior on other instructions on page G2-4505.](#)
- [Usage constraints on page G2-4505.](#)
- [Exception syndrome information and preferred return address on page G2-4508.](#)
- [Pseudocode description of Watchpoint exceptions taken from AArch32 state on page G2-4509.](#)

### G2.10.1 About Watchpoint exceptions

A *watchpoint* is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, [DBGDIDR.WRPs](#) shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, [DBGWCR<n>](#). This holds control information for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, [DBGWVR<n>](#). This holds the data virtual address used for watchpoint matching.

The registers are numbered, so that:

- DBGWCR1 and DBGWVR1 are for watchpoint number one.
- DBGWCR2 and DBGWVR2 are for watchpoint number two.
- ...
- ...
- DBGWCRn and DBGWVRn are for watchpoint number n.

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Linked Context breakpoint*, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.

A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, `DBGWCR<n>.BAS`, to select the bytes. See [Programming a watchpoint with eight bytes or fewer on page G2-4501](#).
- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.
 A debugger uses the *MASK* field, `DBGWCR<n>.MASK`, to program a watchpoint with eight bytes to 2GB. See [Programming a watchpoint with eight or more bytes on page G2-4503](#).

A debugger must use either the *BAS* field or the *MASK* field. If it uses both, whether the watchpoint generates Watchpoint exceptions is CONSTRAINED UNPREDICTABLE. See [Programming dependencies of the BAS and MASK fields on page G2-4506](#).

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, `DBGWCR<n>.E`, is 1.
- The conditions specified in the `DBGWCR<n>` are met.
- The comparison with the address held in the `DBGWVR<n>` is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint are successful. See [on page G2-4474](#) shows this. See also [Breakpoint context comparisons on page G2-4487](#).
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.

If halting is allowed and `EDSCR.HDE` is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

#### ———— **Note** ————

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

[The debug exception enable controls on page G2-4458](#) describes the enable controls for Watchpoint debug events.

## G2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The *Watchpoint Type* field for a watchpoint, `DBGWCR<n>.WT`, controls whether the watchpoint is enabled for linking. If `DBGWCR<n>.WT` is 1, the watchpoint is enabled for linking.

### Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGWCR<n>.LBN`, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  - `DBGWCR<n>.WT`. {SSC, HMC, PAC} for the Linked watchpoint define the execution conditions that the watchpoint generates Watchpoint exceptions for. See [Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-4499](#).
  - `DBGBCR<n>.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See [Usage constraints on page G2-4505](#).
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

#### **Note**

Multiple Address breakpoints can also link to a single Linked Context breakpoint. [Breakpoint exceptions on page G2-4470](#) describes breakpoints.

Figure G2-2 on page G2-4474 shows an example of permitted watchpoint linking.

### G2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2.

**DBGWCR<n>**.{SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

#### Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

##### Note

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

#### Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Privilege level the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level or Privilege level at which the access was made.

##### Note

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at PL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on PL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A32/T32 Load unprivileged and Store unprivileged instructions are LDRT and STRT.

Table G2-15 on page G2-4500 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Privilege levels watchpoints generate Watchpoint exceptions in.

In the table:

<b>Y or -</b>	Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
<b>Y</b>	Can generate Watchpoint exceptions at that Privilege level.
<b>-</b>	Cannot generate Watchpoint exceptions at that Privilege level.
<b>Res</b>	Means that the combination of HMC, SSC, and PAC is reserved. See <i>Reserved DBGWCR&lt;n&gt;.{SSC, HMC, PAC} values on page G2-4506</i> .

**Table G2-15 Summary of watchpoint HMC, SSC, and PAC encodings**

HMC	SSC	PAC	Security state the watchpoint is programmed to match in	PL2 <sup>a</sup>	PL1	PL0	Implementation	
							No EL3	No EL2 and no EL3
0	00	01	Both	-	Y	-	-	-
0	00	10		-	-	Y	-	-
0	00	11		-	Y	Y	-	-
0	01	01	Non-secure	-	Y	-	Res	Res
0	01	10		-	-	Y	Res	Res
0	01	11		-	Y	Y	Res	Res
0	10	01	Secure	-	Y	-	Res	Res
0	10	10		-	-	Y	Res	Res
0	10	11		-	Y	Y	Res	Res
1	00	01	Both	Y	Y	-	-	Res
1	00	11		Y	Y	Y	-	Res
1	01	01	Non-secure	Y	Y	-	Res	Res
1	01	11		Y	Y	Y	Res	Res
1	10	01	Secure	-	Y	-	Res	Res
1	10	11		-	Y	Y	Res	Res
1	11	00	Non-secure	Y	-	-	-	Res if no EL2 <sup>b</sup>

- a. Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PAC that generate Watchpoint exceptions at PL2 using AArch32.
- b. This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See [Reserved DBGWCR<n>.{SSC, HMC, PAC} values on page G2-4506](#).

#### G2.10.4 Watchpoint data address comparisons

An address comparison is successful if bits [31:2] of the current data virtual address are equal to [DBGWVR<n>\[31:2\]](#), taking into account all of the following:

- The size of the access. See [Size of the data access on page G2-4501](#).
- The bytes selected by [DBGWVR<n>.BAS](#). See [Programming a watchpoint with eight bytes or fewer on page G2-4501](#).
- Any address ranges indicated by [DBGWVR<n>.MASK](#). See [Programming a watchpoint with eight or more bytes on page G2-4503](#).

———— **Note** —————  
[DBGWVR<n>\[1:0\]](#) are RES0 and are ignored.

## Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each access must be taken into account. See [Example G2-1](#).

### Example G2-1

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address 0x1009 is accessed.
2. The PE accesses the unaligned doubleword starting at address 0x1003.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by DCIMVAC instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that [CTR.DminLine](#) defines.
  - 2KB.
- A power-of-two.

The lowest address accessed by a DCIMVAC instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.

The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, [Watchpoint behavior on accesses by DCIMVAC instructions](#) on page G2-4505.

## Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, [DBGWCR<n>.BAS](#), selects which bytes in the doubleword starting at the address contained in the [DBGWVR<n>](#) the watchpoint generates Watchpoint exceptions for.

If the address programmed into the [DBGWVR<n>](#) is:

- Doubleword-aligned:
  - All eight bits of [DBGWCR<n>.BAS](#) are used, and the descriptions given in [Table G2-16](#) apply.
- Word-aligned but not doubleword-aligned:
  - Only [DBGWCR<n>.BAS\[3:0\]](#) are used, and the descriptions given in [Table G2-17 on page G2-4502](#) apply. In this case, [DBGWCR<n>.BAS\[7:4\]](#) are RES0.

**Table G2-16 Supported BAS values when the DBGWVRn address alignment is doubleword**

BAS value	Description
0b00000000	Watchpoint never generates a Watchpoint exception
BAS[0] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:3]:000</a> is accessed
BAS[1] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:3]:001</a> is accessed
BAS[2] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:3]:010</a> is accessed
BAS[3] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:3]:011</a> is accessed
BAS[4] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:3]:100</a> is accessed

**Table G2-16 Supported BAS values when the DBGWVRn address alignment is doubleword**

BAS value	Description
BAS[5] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:3]:101</a> is accessed
BAS[6] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:3]:110</a> is accessed
BAS[7] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:3]:111</a> is accessed

**Table G2-17 Supported BAS values when the DBGWVRn address alignment is word**

BAS value <sup>a</sup>	Description
0b00000000	Watchpoint never generates a Watchpoint exception
BAS[0] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:2]:00</a> is accessed
BAS[1] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:2]:01</a> is accessed
BAS[2] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:2]:10</a> is accessed
BAS[3] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;[31:2]:11</a> is accessed

a. [DBGWCR<n>.BAS\[7:4\]](#) are RES0.

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see [Other usage constraints on page G2-4507](#).

When programming the BAS field with anything other than 0b11111111, a debugger must also program [DBGWCR<n>.MASK](#) to be 0b00000. See [Programming dependencies of the BAS and MASK fields on page G2-4506](#).

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the [DBGWVR<n>\[31:3\]](#). See [Example G2-1 on page G2-4501](#).

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - [DBGWVR<n>](#) with 0x1000.
  - [DBGWCR<n>\\_EL1.BAS](#) to be 0b00001000.
- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  - [DBGWVR<n>](#) with 0x2000.
  - [DBGWCR<n>\\_EL1.BAS](#) to be 0b00111000.
- If the address programmed into the [DBGWVR<n>](#) is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program [DBGWCR<n>.BAS](#) to be 0b00001111.
  - To generate a Watchpoint exception when any byte in the word starting at address [DBGWVR<n>\[31:3\]:100](#) is accessed, program [DBGWCR<n>.BAS](#) to be 0b11110000.

---

**Note**

---

ARM deprecates programming a [DBGWVR<n>](#) with an address that is not doubleword-aligned.

---

**Programming a watchpoint with eight or more bytes**

A debugger can use the *MASK* field, [DBGWCR<n>.MASK](#), to program a single watchpoint with a data address range. The data address range must meet all of the following criteria:

- It is a size that is both:
  - A power-of-two.
  - A minimum of eight bytes.
  - A maximum of 2GB.
- It starts at an address that is aligned to the size.

The *MASK* field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

<b>MASK</b>	0b00000	No bits are masked.
	0b00001	Reserved.
	0b00010	Reserved.
	0b00011	Three least significant bits are masked.
	0b00100	Four least significant bits are masked.
	0b00101	Five least significant bits are masked.
	...	...
	0b11111	31 least significant bits are masked.

If *n* least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address [DBGWVR<n>](#)[31:*n*]:000...
- Address [DBGWVR<n>](#)[31:*n*]:111...
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between [DBGWVR<n>](#)[31:4]:0000 and [DBGWVR<n>](#)[31:4]:1111, including these addresses.

---

**Note**

---

- The most significant bit cannot be masked. This means that the full address cannot be masked.
  - For watchpoint behavior when its *MASK* field is programmed with a reserved value, see [Reserved DBGWCR<n>.MASK values on page G2-4507](#).
- 

When masking address bits, a debugger must both:

- Program [DBGWCR<n>.BAS](#) to be 0b11111111. See [Programming dependencies of the BAS and MASK fields on page G2-4506](#).
- In the [DBGWVR<n>](#), set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see [Other usage constraints on page G2-4507](#).

## G2.10.5 Determining the memory location that caused a Watchpoint exception

On a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- [DFAR](#), if the exception is taken to PL1.
- [HDFAR](#), if the exception is taken to PL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the [EDWAR](#).

---

### Note

If Debug state was entered from AArch32 state, then [EDWAR](#)[63:32] is UNKNOWN and must be ignored by the debugger.

---

For more information, see the subsections that follow. These are:

- [Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions.](#)
- [Address recorded for Watchpoint exceptions generated by Data Cache instructions on page G2-4505.](#)

### Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions

The address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access that triggered the watchpoint.
  - The highest *watchpointed address* accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.
- Within a naturally-aligned block of memory that is all of the following:
  - A power-of-two size.
  - No larger than 2KB.
  - No larger than the block size used by the A64 [DC ZVA](#) instruction.

---

### Note

There are no architectural means to discover the A64 [DC ZVA](#) instruction block size from AArch32 state.

---

- Contains a watchpointed address accessed by the memory access.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

### Example G2-2 Address recorded for a watchpoint programmed on 0x8019

---

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:

- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
  - 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.
-

## Address recorded for Watchpoint exceptions generated by Data Cache instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

### G2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Preload instructions.
- All data cache maintenance instructions except DCIMVAC.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an IMPLEMENTATION DEFINED subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are IMPLEMENTATION DEFINED.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also:

- [Watchpoint behavior on accesses by Store-Exclusive instructions.](#)
- [Watchpoint behavior on accesses by DCIMVAC instructions.](#)

### Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

### Watchpoint behavior on accesses by DCIMVAC instructions

It is IMPLEMENTATION DEFINED whether DCIMVAC operations can generate Watchpoint exceptions. If they can, they are treated as data stores. This means that for a watchpoint to match on an access caused by a DCIMVAC instruction, the debugger must program DBGWCR<n>.LSC to be one of the following:

- 10** Match on data stores only.
- 11** Match on data stores and data loads.

#### ———— Note ————

For the size of data accesses performed by DCIMVAC instructions, see [Watchpoint data address comparisons on page G2-4500](#). The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

### G2.10.7 Usage constraints

See the following:

- [Reserved DBGWCR<n>.{SSC, HMC, PAC} values on page G2-4506.](#)
- [Reserved DBGWCR<n>.LBN values on page G2-4506.](#)
- [Programming dependencies of the BAS and MASK fields on page G2-4506.](#)
- [Reserved DBGWCR<n>.BAS values on page G2-4507.](#)
- [Reserved DBGWCR<n>.MASK values on page G2-4507.](#)
- [Other usage constraints on page G2-4507.](#)

## Reserved DBGWCR<n>.{SSC, HMC, PAC} values

Table G2-18 shows when particular combinations of DBGWCR<n>.{SSC, HMC, PAC} are reserved.

**Table G2-18 Reserved SSC, HMC, and PAC combinations**

HMC, SSC, and PMC combination	Reserved
All combinations with SSC set to 0b01 or 0b10.	When EL3 is not implemented and EL2 is implemented.
All combinations where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00.	When both of EL2 and EL3 are not implemented
The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00.	When EL2 is not implemented
Combinations not included in Table G2-15 on page G2-4500.	Always

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<n>.
- For a direct or external read of DBGWCR<n>, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

## Reserved DBGWCR<n>.LBN values

### For Linked watchpoints

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGWCR<n>.LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

### For Unlinked watchpoints

For Unlinked watchpoints, DBGWCR<n>.LBN reads UNKNOWN and its value is ignored.

## Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n> the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be 0b1111111, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be 0b00000, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is non-zero and a BAS field that is not set to 0b1111111, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

### Reserved DBGWCR<n>.BAS values

The BAS field must be programmed with a value `Zeros(8-n-m):Ones(n):Zeros(m)`, where:

- $n$  is a non-zero positive integer less-than-or-equal-to 8.
- $m$  is a positive integer less-than 8.
- $n+m$  is less-than-or-equal-to 8.

All other values are reserved.

#### ———— Note ————

If  $x$  is zero, then `Zeros(x)` is an empty bitstring.

If `DBGWVR<n>[2]` is 1, `DBGWCR<n>.BAS[7:4]` are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the `DBGWVR<n>`.
- A direct or external read of `DBGWCR<n>.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

### Reserved DBGWCR<n>.MASK values

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with an UNKNOWN value that is not reserved, that might be 0b00000, other than for a direct or external read of `DBGWCR<n>`.
- A direct or external read of `DBGWCR<n>.MASK` returns an UNKNOWN value.

### Other usage constraints

For all watchpoints:

- `DBGWVR<n>[1:0]` are RES0 and are ignored.
- If `DBGWCR<n>.MASK` is nonzero, and any masked bits of `DBGWVR<n>` are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if `DBGWCR<n>.LSC` is 0b00.

## G2.10.8 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address on page G2-4509](#).

### Exception syndrome information

The PE takes a Watchpoint exception as either:

- A Data Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because [HCR.TGE](#) or [HDCR.TDE](#) is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

#### Abort mode

The PE sets all of the following:

- [DBGDSCRext.MOE](#) to 0b1010, to indicate a Watchpoint exception.
- [DFSR.CM](#) to indicate whether a cache maintenance instruction caused the exception.
- [DFSR.WnR](#) to indicate whether the exception was generated on a read instruction or a write instruction.
- [DFAR](#) to an address that the debugger can use to determine the memory location that triggered the watchpoint. See [Determining the memory location that caused a Watchpoint exception on page G2-4504](#).

In addition, if using the:

- Short-descriptor format, the PE sets [DFSR.FS](#) to the code for a debug exception, 0b00010, and [DFSR.Domain](#) to an UNKNOWN value.
- Long-descriptor format, the PE sets [DFSR.STATUS](#) to the code for a debug exception, 0b100010.

#### Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, [HSR](#). See [Table G2-19 on page G2-4509](#).
- Sets [DBGDSCRext.MOE](#) to 0b1001, to indicate a Watchpoint exception.
- Sets the [HDFAR](#) to an address that the debugger can use to determine the memory location that triggered the watchpoint. See [Determining the memory location that caused a Watchpoint exception on page G2-4504](#).

Table G2-19 Information recorded in the HSR

HSR field	Information recorded
<i>Exception Class</i> , EC	The PE sets this to the code for a Data Abort exception routed to Hyp mode, 0x24.
<i>Instruction Length</i> , IL	The PE sets this to 1.
<i>Instruction Specific Syndrome</i> , ISS	<b>ISV[24]</b> <i>Instruction Syndrome Valid</i> (ISV). The PE sets this to 0. <b>ISS[23:10]</b> RES0. <b>ISS[9]</b> <i>External Abort type</i> (EA). The PE sets this to 0. <b>ISS[8]</b> <i>Cache Maintenance</i> (CM). The PE sets this to indicate whether a cache maintenance instruction caused the exception. <b>ISS[7]</b> RES0. <b>ISS[6]</b> <i>Write not Read</i> (WnR). The PE sets this to indicate whether the exception was generated on a read instruction or a write instruction. <b>ISS[5:0]</b> <i>Data Fault Status Code</i> (DFSC). The PE sets this to the code for a debug exception, 0b100010.

**Note**

For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions on page G2-4459](#).

**Preferred return address**

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

**G2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch32 state**

`AArch32.WatchpointByteMatch()` tests an individual byte accessed by an operation.

`AArch32.StateMatch()` tests the values in `DBGWCR<n>`. {HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

`AArch32.WatchpointMatch()` tests the value in `DBGWVR<n>`.

`AArch32.CheckWatchpoint()` generates a `FaultRecord`. A Watchpoint exception is taken if all of the following are true:

- `DBGDSCRext.MDBGen` is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Privilege level and Security state on page G2-4461](#).
- All of the conditions required for Watchpoint exception generation are met. See [About Watchpoint exceptions on page G2-4496](#).

**Note**

`AArch32.CheckWatchpoint` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The `AArch32.Abort()` function processes the `FaultRecord` object returned by `AArch32.CheckWatchpoint()`, as described in [Abort exceptions on page G3-4555](#). If a Watchpoint exception is taken to AArch32 state, the `AArch32.Abort()` function generates a Data Abort exception.

## G2.11 Vector Catch exceptions

ARM deprecates the use of vector catch.

This section describes Vector Catch exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:

- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

---

### Note

Vector Catch exceptions cannot be generated when the PE is using an AArch64 translation regime.

---

This section contains the following subsections:

- [About Vector Catch exceptions.](#)
- [Exception vectors that Vector Catch exceptions can be enabled for on page G2-4512.](#)
- [Generation of Vector Catch exceptions on page G2-4513.](#)
- [Usage constraints on page G2-4515.](#)
- [Exception syndrome information and preferred return address for a Vector Catch exception on page G2-4516.](#)
- [Pseudocode description of Vector Catch exceptions on page G2-4517.](#)

### G2.11.1 About Vector Catch exceptions

Whenever the PE takes an exception, execution is forced to an address that is the *exception vector* for that exception. Vector catch permits a debugger to trap exceptions based on the exception vector, or based on the exception type associated with the exception vector, as follows:

- If the *address-matching* form of vector catch is implemented, the debugger can trap exceptions based on the exception vector.
- If the *exception-trapping* form of vector catch is implemented, the debugger can trap exceptions based on the exception type associated with the exception vector.

The ARMv8-A architecture supports only these two forms of vector catch. Only one form can be implemented, and which is implemented is IMPLEMENTATION DEFINED. The [DBGDEVID](#) indicates which form is implemented.

Regardless of the form of vector catch implemented, a debugger enables Vector Catch exceptions for exception vectors or types by programming the [DBGVCR](#). This register contains *vector catch enable bits*. Each of these bits corresponds to a different vector. When a debugger sets a vector catch enable bit to 1, Vector Catch exceptions are enabled for the corresponding exception vector or type.

---

### Note

EL2 using AArch64 or EL3 using AArch64 can enable Vector Catch exceptions for vectors by programming the [DBGVCR32\\_EL2](#). The [DBGVCR32\\_EL2](#) is architecturally mapped to the [DBGVCR](#).

---

When Vector Catch exceptions are enabled for an exception vector, this is called an *enabled vector catch*. The set of exception vectors that Vector Catch exceptions are enabled for is called the *enabled vector catch set*.

If the form of vector catch implemented is the:

#### Address-matching form:

The PE compares the virtual address of each instruction in the program flow with a subset of the enabled vector catch set.

If an address match occurs, a Vector Catch exception is generated when the instruction that caused the match is committed for execution.

**Exception-trapping form**

Whenever the PE takes an exception, if the vector the exception is taken to is included in a subset of the enabled vector catch set, a Vector Catch exception is generated.

The Vector Catch exception is generated as part of entry to the exception, and must be taken before the PE either executes any instructions or takes any further exceptions.

The addresses that comprise the subset depend on whether EL3 is implemented and, for the:

- Address-matching form, the current Security state.
- Exception-trapping form, the Security state that the exception is handled in.

See [Generation of Vector Catch exceptions on page G2-4513](#).

[Table G2-20](#) summarizes the differences between the address-matching and exception-trapping forms.

**Table G2-20 Differences in behavior of the address-matching and exception-trapping forms of vector catch**

Address-matching	Exception-trapping
<p>An enabled vector catch generates a Vector Catch exception when an instruction that is fetched from the vector is committed for execution.</p> <p>This means that spurious Vector Catch exceptions might occur, where the Vector Catch exception does not result from an exception entry, but is instead caused by a branch to the vector.</p> <p>A branch to the vector might occur, for example, on a return from a nested exception or when simulating an exception entry.</p>	<p>An enabled vector catch generates a Vector Catch exception immediately after the PE takes the exception that is associated with the vector.</p> <p>This means that Vector Catch exceptions always result from exception entry, and not from branches to exception vectors.</p>
<p>A Vector Catch exception is generated as a result of an instruction fetch. This means that the Vector Catch exception has a priority relative to the other synchronous exceptions that result from an instruction fetch.</p> <p><a href="#">Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827</a> describes this prioritization.</p>	<p>A Vector Catch exception is generated as a result of an exception entry. This means that the Vector Catch exception is part of the exception that caused the Vector Catch exception. Therefore, the Vector Catch exception has no priority associated with it.</p> <p>For this reason, Vector Catch exceptions are outside the scope of the prioritization that <a href="#">Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827</a> describes.</p>
<p>A Vector Catch exception can be preempted by another exception. If this happens, the Vector Catch exception is generated again when the exception handler branches back to the vector.</p>	<p>Vector Catch exceptions must be taken before other exceptions.</p>
<p>A Vector Catch exception can be generated as a result of an instruction fetch executed in any AArch32 mode except Hyp mode, including User mode.</p>	<p>Because a Vector Catch exception is generated as the result of an exception entry, the Vector Catch exception is only generated when the PE is in the AArch32 exception handling mode.</p>
<p>If <b>HCR.TGE</b> is 1, Vector Catch exceptions can be generated for User mode instruction fetches from Non-secure PL1 vectors.</p>	<p>If <b>HCR.TGE</b> is 1, Vector Catch exceptions are never generated in Non-secure state, because:</p> <ul style="list-style-type: none"> <li>• Exceptions are routed away from Non-secure PL1 vectors, to PL2.</li> <li>• The architecture does not provide vector catch enable bits for the Hyp exception vectors.</li> </ul>

Depending on the implementation, some vector catch enable bits in the **DBGVCR** might be RES0. For example, if EL3 is not implemented or is implemented but is using AArch64, Monitor mode is not implemented, and so the enable bits for exception vectors for exceptions taken to Monitor mode are RES0. See [Exception vectors that Vector Catch exceptions can be enabled for on page G2-4512](#) for the vector catch enable bits that exist for different implementations.

[The debug exception enable controls on page G2-4458](#) describes the enable controls for Vector Catch exceptions.

## G2.11.2 Exception vectors that Vector Catch exceptions can be enabled for

When the PE takes an exception, the exception vector is contained in a *vector table* at the Privilege level the exception is taken to.

Depending on the Security state and AArch32 mode the exception is taken to, when the exception is taken, the vector table used is the table that contains one of:

- *Local exception vectors.*
- *Non-secure Local exception vectors.*
- *Secure Local exception vectors.*
- *Hyp exception vectors.*
- *Monitor exception vectors.*

Table G2-21 shows which vector tables are implemented for different implementations. In the table:

- A dash, -, means that the Exception level is not implemented.
- 64 means that the Exception level is using AArch64.
- 32 means that the Exception level is using AArch32.

**Table G2-21 Vector tables implemented for different implementations**

Implementation				Vector table or tables implemented
EL0	EL1	EL2	EL3	
32	32	-	-	Local exception vectors.
		64	-	Non-secure Local exception vectors.
		32	-	Non-secure Local exception vectors. Hyp exception vectors.
		-	64	Secure Local exception vectors. Non-secure Local exception vectors.
		-	32	Secure Local exception vectors. Non-secure Local exception vectors. Monitor exception vectors.
		64	64	Secure Local exception vectors. Non-secure Local exception vectors.
		32	64	Secure Local exception vectors. Non-secure Local exception vectors. Hyp exception vectors.
		32	32	Secure Local exception vectors. Non-secure Local exception vectors. Hyp exception vectors. Monitor exception vectors.

For example, in an AArch32-only implementation that includes EL0, EL1, and EL3, when the PE takes an exception to Monitor mode, it uses the vector table containing Monitor exception vectors.

The tables that follow show the vectors that Vector Catch exceptions can be enabled for, and their corresponding vector catch enable bits in the [DBGVCR](#):

- [Table G2-22](#) shows the Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for.
- [Table G2-23](#) shows the Monitor exception vectors that Vector Catch exceptions can be enabled for.

The ARMv8-A architecture does not provide vector catch enable bits for the Hyp exception vectors.

**Table G2-22 Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for**

Vector catch enable bit		Exception type	Local exception vectors	
Local or Secure Local exception vectors	Non-secure Local exception vectors		Normal. <a href="#">SCTLR.V</a> is 0. <sup>a</sup>	High. <a href="#">SCTLR.V</a> is 1.
SF	NSF	FIQ interrupt	<a href="#">VBAR</a> + 0x0000001C	0xFFFF001C
SI	NSI	IRQ interrupt	<a href="#">VBAR</a> + 0x00000018	0xFFFF0018
SD	NSD	Data Abort	<a href="#">VBAR</a> + 0x00000010	0xFFFF0010
SP	NSP	Prefetch Abort	<a href="#">VBAR</a> + 0x0000000C	0xFFFF000C
SS	NSS	Supervisor Call	<a href="#">VBAR</a> + 0x00000008	0xFFFF0008
SU	NSU	Undefined Instruction	<a href="#">VBAR</a> + 0x00000004	0xFFFF0004

- a. If EL3 is implemented and is using AArch32, [VBAR](#) is banked. The Secure Local exception vectors use [VBAR<sub>S</sub>](#) and the Non-secure Local Exception vectors use [VBAR<sub>NS</sub>](#).

**Table G2-23 Monitor exception vectors that Vector Catch exceptions can be enabled for**

Vector catch enable bit	Exception type	Monitor exception vectors
MF	FIQ interrupt	<a href="#">MVBAR</a> + 0x0000001C
MI	IRQ interrupt	<a href="#">MVBAR</a> + 0x00000018
MD	Data Abort	<a href="#">MVBAR</a> + 0x00000010
MP	Prefetch Abort	<a href="#">MVBAR</a> + 0x0000000C
MS	Secure Monitor Call	<a href="#">MVBAR</a> + 0x00000008

**Note**

There is no vector catch enable bit for Monitor trap exceptions.

### G2.11.3 Generation of Vector Catch exceptions

How Vector Catch exceptions are generated depends on which form is implemented:

- [Address-matching form on page G2-4514.](#)
- [Exception-trapping form on page G2-4514.](#)

## Address-matching form

The PE compares the virtual address of each instruction in the program flow is with some or all of the addresses in the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE compares the virtual address of each instruction in the program flow, including those executed at EL0, with all addresses in the enabled vector catch set.
- If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  - Monitor exception vectors, if EL3 is using AArch32.
  - Secure Local exception vectors.
  - Non-secure Local exception vectors.

In this case, [Table G2-24](#) shows which addresses, in the enabled vector catch set, the virtual address of each instruction in the program flow is compared with.

**Table G2-24 Comparisons made if the implementation includes EL3**

EL3 is using	For exceptions taken to:	
	Secure PL1 modes	Non-secure PL1 modes
AArch64	Secure Local exception vectors	Non-secure Local exception vectors
AArch32	Secure Local exception vectors and Monitor exception vectors	

For example, for exceptions taken to a Secure PL1 mode when EL3 is using AArch64, the virtual address of each instruction in the program flow is compared with each Secure Local exception vector in the enabled vector catch set.

For each instruction in the program flow, the PE tests for any possible Vector Catch exceptions before executing the instruction. If a match occurs, a Vector Catch exception is generated when the instruction is committed for execution, regardless of all of the following:

- Whether the instruction passes its Condition code check.
- Whether the instruction is executed as part of exception entry.
- If EL2 is implemented, what [HCR](#). {IMO, FMO, AMO} are set to.
- If EL3 is implemented, what [SCR](#). {IRQ, FIQ, EA} are set to.

## Exception-trapping form

When the PE takes an exception, it tests whether the exception is by branching to an exception vector in a subset of the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE tests whether the exception is by branching to any address in the enabled vector catch set.
- If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  - Monitor exception vectors, if EL3 is using AArch32.
  - Secure Local exception vectors.
  - Non-secure Local exception vectors.

In this case, the PE tests whether the exception is by branching to a vector in one of the subsets that [Table G2-25](#) shows. In the table, n/a means not applicable.

**Table G2-25 Subsets that the PE tests within if EL3 is implemented**

EL3 is using	For exceptions taken to:		
	Monitor mode	Other Secure PL1 modes	Non-secure PL1 modes
AArch64	n/a	Secure Local exception vectors	Non-secure Local exception vectors
AArch32	Monitor exception vectors		

For example, for an exception taken to a Secure PL1 mode when EL3 is using AArch64, the PE tests whether the exception is by branching to any of the Secure Local exception vectors in the enabled vector address set.

If the exception is by branching to a vector in the subset, a Vector Catch exception is generated as part of exception entry. That is, a Vector Catch exception is generated instead of the exception handler executing its first instruction.

#### G2.11.4 Usage constraints

See the following subsections:

- [Usage constraints that apply to both forms of vector catch.](#)
- [Usage constraints that apply only to the address-matching form.](#)

##### Usage constraints that apply to both forms of vector catch

For Vector Catch exceptions enabled for either the Prefetch Abort exception vector or the Data Abort exception vector, if one of these exception types is taken to the Exception level that debug exceptions are targeting, behavior is CONSTRAINED UNPREDICTABLE. Either:

- Vector catch is ignored, therefore a Vector Catch exception is not generated.
- Vector catch generates a Prefetch Abort debug exception. For Vector Catch exceptions enabled for the Prefetch Abort exception vector, the PE might enter a recursive loop of Prefetch Abort exceptions causing Vector Catch exceptions and Vector Catch exceptions causing Prefetch Abort exceptions.

##### ———— Note ————

The Exception level that debug exceptions are targeting is called the *debug target Exception level*, EL<sub>D</sub>. [Routing debug exceptions on page G2-4459](#) describes how EL<sub>D</sub> is derived.

##### Usage constraints that apply only to the address-matching form

Exception vectors are at word-aligned addresses, and:

- It is CONSTRAINED UNPREDICTABLE whether an enabled vector catch generates a Vector Catch exception for a 32-bit T32 instruction starting at the halfword-aligned address immediately prior to the vector address.
- T32 instructions that start at the halfword-aligned address immediately after the exception vector do not generate Vector Catch exceptions.

For the address-matching form, Vector Catch exceptions have the same priority as Breakpoint exceptions. If a single instruction causes both a Vector Catch exception and a Breakpoint exception, it is CONSTRAINED UNPREDICTABLE which of these debug exceptions the PE takes.

G2.11.5 Exception syndrome information and preferred return address for a Vector Catch exception

See the following:

- [Exception syndrome information for a Vector Catch exception.](#)
- [Preferred return address for a Vector Catch exception on page G2-4517.](#)

———— **Note** ————

Usually, the term *exception syndrome* is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced section uses the term more generally, to include exception information reported in the [IFSR](#).

**Exception syndrome information for a Vector Catch exception**

The PE takes a Vector Catch exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because [HCR.TGE](#) or [HDCR.TDE](#) is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

**PL1 Abort mode**

The PE sets all of the following:

- [IFSR.FS](#) to the code for a debug exception, 0b00010.
- [DBGDSCRExt.MOE](#) to 0b0101, to indicate a Vector Catch exception.
- The [IFAR](#) with an UNKNOWN value.

**PL2 Hyp mode**

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, [HSR](#). See [Table G2-26](#).
- Sets [DBGDSCRExt.MOE](#) to 0b0101, to indicate a Vector Catch exception.
- Sets the [HIFAR](#) to an unknown value.

**Table G2-26 Information recorded in the [HSR](#)**

<b>HSR field</b>	<b>Information recorded</b>
<i>Exception Class</i> , EC	The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, 0x20.
<i>Instruction Length</i> , IL	The PE sets this to 1.
<i>Instruction Specific Syndrome</i> , ISS	<b>ISS[24:10]</b> RES0. <b>ISS[9]</b> <i>External Abort type</i> (EA). The PE sets this to 0. <b>ISS[8:6]</b> RES0. <b>ISS[5:0]</b> <i>Instruction Fault Status Code</i> (IFSC). The PE sets this to the code for a debug exception, 0b100010.

———— **Note** ————

For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions on page G2-4459](#).

### Preferred return address for a Vector Catch exception

The preferred return address of a Vector Catch exceptions is the address of the instruction that was not executed because the PE took the Vector Catch exception instead.

This means that the preferred return address is the exception vector. This is true regardless of whether the address-matching form or the exception trapping form is implemented.

#### G2.11.6 Pseudocode description of Vector Catch exceptions

The `AArch32.VCRMatch()` pseudocode function checks whether the instruction at address generates a Vector Catch exception. It therefore shows the address-matching form of vector catch.

The `AArch32.CheckVectorCatch()` pseudocode function uses `AArch32.VCRMatch()` to test whether the instruction generates a Vector Catch exception, and if `AArch32.VCRMatch()` returns TRUE it generates that event.

The `AArch32.Abort()` function processes the Faultrecord object returned by `AArch32.CheckVectorCatch()`, as described in *Abort exceptions on page G3-4555*. If there is a Vector Catch exception, the `AArch32.Abort()` function generates a Prefetch Abort exception.

## G2.12 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a [Context synchronization event](#) has occurred.

For any instructions executed between the time when the change is made and the time when the next [Context synchronization event](#) occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

### Example G2-3

---

1. Software changes [DBGDSCRExt.MDBGGen](#) from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A [Context synchronization event](#) occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

---

### Example G2-4

---

1. Software unlocks the OS lock.
2. The PE executes some instructions.
3. A [Context synchronization event](#) occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

---

#### ———— Note ————

Some register updates are self-synchronizing. Others require an explicit [Context synchronization event](#). For more information, see:

- [Synchronization of changes to AArch32 System registers on page G6-4768.](#)
  - [Accessing PSTATE fields on page G1-4333.](#)
  - [Synchronization of changes to the external debug registers on page H8-5554.](#)
-

### G2.12.1 State and mode changes without explicit context synchronization events

Most changes to the Exception level, and most changes to the Security state if EL3 is implemented, happen as a result of operations that are an explicit *Context synchronization event*. This is because taking an exception and returning from an exception are both explicit *Context synchronization events*, and the Privilege level and Security state can only change as a result of taking or returning from an exception.

However, some Security state and AArch32 mode changes can happen because of operations that are not an explicit *Context synchronization event*. These are:

- AArch32 mode changes caused by MSR and CPS instructions. A mode change might be to a mode at a lower Privilege level.
- If EL3 is using AArch32, a Security state change caused by a direct write to the SCR in a privileged mode other than Monitor mode, to set SCR.NS to 1.

# Chapter G3

## The AArch32 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- *About the memory system architecture on page G3-4522.*
- *Address space on page G3-4523.*
- *Mixed-endian support on page G3-4524.*
- *AArch32 cache and branch predictor support on page G3-4525.*
- *System register support for IMPLEMENTATION DEFINED memory features on page G3-4549.*
- *External aborts on page G3-4550.*
- *Memory barrier instructions on page G3-4552.*
- *Pseudocode description of general memory system instructions on page G3-4553.*

### G3.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see [Memory hierarchy on page E2-2772](#).

#### G3.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a *Virtual Memory System Architecture* (VMSA). [Chapter G4 The AArch32 Virtual Memory System Architecture](#) describes the AArch32 view of the VMSA.

#### G3.1.2 Memory attributes

[Memory types and attributes on page E2-2782](#) describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

[Table G3-1](#) shows the memory attributes that are visible at the system level.

**Table G3-1 Memory attribute summary**

Memory type	Shareability	Cacheability
Device <sup>a</sup>	Outer Shareable	Non-cacheable.
Normal	One of: <ul style="list-style-type: none"><li>Non-shareable.</li><li>Inner Shareable.</li><li>Outer Shareable.</li></ul>	One of <sup>b</sup> : <ul style="list-style-type: none"><li>Non-cacheable.</li><li>Write-Through Cacheable.</li><li>Write-Back Cacheable.</li></ul>

a. Takes additional attributes, see [Device memory on page E2-2786](#).

b. See also [Cacheability, cache allocation hints, and cache transient hints on page G3-4528](#).

For more information on Cacheability and Shareability see [The Cacheability and Shareability memory attributes on page E2-2773](#), [Non-shareable Normal memory on page E2-2784](#), and [Caches and memory hierarchy on page E2-2772](#).

## G3.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *physical address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see [About VMSAv8-32 on page G4-4558](#).

### G3.2.1 Address space overflow or underflow

This subsection describes address space overflow or underflow:

#### Instruction address space overflow

When a PE performs a normal, sequential execution of instructions, it calculates:

$$(\text{address\_of\_current\_instruction}) + (\text{size\_of\_executed\_instruction})$$

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an A32 or T32 instruction overflows 0xFFFF FFFF, the program counter becomes UNKNOWN.

If the PE executes an instruction for which the instruction address, size, and alignment mean that it contains the bytes 0xFFFFFFFF and 0x00000000, the bytes that apparently from 0x00000000 onwards come from an UNKNOWN address.

#### Data address space overflow and underflow

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean that it accesses bytes 0xFFFFFFFF and 0x00000000, then the bytes that apparently come from 0x00000000 onwards come from UNKNOWN addresses.

## G3.3 Mixed-endian support

Table G3-2 shows the endianness of explicit data accesses and translation table walks.

**Table G3-2 Endianness support**

Exception level	Explicit data accesses	Stage 1 translation table walks	Stage 2 translation table walks
EL0	<a href="#">PSTATE.E</a>	<a href="#">SCTLR(S/NS).EE</a>	<a href="#">HSCTLR.EE</a>
EL1	<a href="#">PSTATE.E</a>	<a href="#">SCTLR(S/NS).EE</a>	<a href="#">HSCTLR.EE</a>
EL2	<a href="#">PSTATE.E</a>	<a href="#">HSCTLR.EE</a>	N/A
EL3	<a href="#">PSTATE.E</a>	<a href="#">SCTLR(S).EE</a>	N/A

AArch32 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - [SCTLR\(S/NS\).EE](#), [HSCTLR.EE](#), and [PSTATE.E](#) are RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - [SCTLR\(S/NS\).EE](#) and [HSCTLR.EE](#) are RES0. [PSTATE.E](#) is RW when in EL0 and RES0 when in EL1, EL2, or EL3. [SPSR.E](#) is also RES0 when not returning to EL0.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - [SCTLR\(S/NS\).EE](#) and [HSCTLR.EE](#) are RES1. [PSTATE.E](#) is RW when in EL0 and RES1 when in EL1, EL2, or EL3. [SPSR.E](#) is also RES1 when not returning to EL0.
- All Exception levels support only little-endianness:
  - Each of [SCTLR\(S/NS\).EE](#), [HSCTLR.EE](#), [PSTATE.E](#), and [SPSR.E](#) is RES0.
- All Exception levels support only big-endianness:
  - Each of [SCTLR\(S/NS\).EE](#), [HSCTLR.EE](#), [PSTATE.E](#), and [SPSR.E](#) is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by [PSTATE.E](#). For exception returns to AArch32 state, [PSTATE.E](#) is copied from [SPSR\\_ELx.E](#). If the target Exception level supports only little-endian accesses, [SPSR\\_ELx.E](#) is RES0. If the target Exception level supports only big-endian accesses, [SPSR\\_ELx.E](#) is RES1.

### Note

- When using AArch32, ARM deprecates [PSTATE.E](#) having a different value from the equivalent System register EE bit when in EL1, EL2 or EL3. The use of the SETEND instruction is also deprecated.
- If the higher Exception levels are using AArch64, the corresponding registers are:
  - [SCTLR\\_EL1](#) for [SCTLR\(NS\)](#).
  - [SCTLR\\_EL2](#) for [HSCTLR](#).
  - [SCTLR\\_EL3](#) for [SCTLR\(S\)](#).

The [BigEndian\(\)](#) function determines whether the current Exception level and Execution state is using big-endian data.

For more information about endianness in the ARM architecture see [Endian support on page E2-2779](#).

## G3.4 AArch32 cache and branch predictor support

The following sections describe the support for caches and branch predictors in AArch32 state:

- [General behavior of the caches.](#)
- [Cache identification on page G3-4527.](#)
- [Cacheability, cache allocation hints, and cache transient hints on page G3-4528.](#)
- [Enabling and disabling the caching of memory accesses in AArch32 state on page G3-4529.](#)
- [Behavior of caches at reset on page G3-4531.](#)
- [AArch32 cache and branch predictor maintenance instructions on page G3-4535.](#)
- [About cache maintenance in AArch32 state on page G3-4531.](#)
- [AArch32 cache and branch predictor maintenance instructions on page G3-4535.](#)
- [Cache lockdown on page G3-4546.](#)
- [System level caches on page G3-4547.](#)

See also [Chapter G4 The AArch32 Virtual Memory System Architecture](#), and in particular [Caches in VMSAv8-32 on page G4-4646](#).

---

### Note

---

- Branch predictors typically use a form of cache to hold branch target data. Therefore, they are included in this section.
  - In the instruction mnemonics, MVA is a synonym for VA.
- 

### G3.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

---

**Note**

---

For more information, see [The interaction of cache lockdown with cache maintenance instructions on page G3-4546](#).

---

- Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.
- It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.
- It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
  - The translation regime at the current Exception level.
  - The translation regime at any higher Exception level.
- For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all masters in its Shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the Shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the CTR identifies the Cache Write-back Granule, see [CTR, Cache Type Register on page G6-4843](#).
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

---

**Note**

---

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the [SCTLR](#). {I, C} controls.

---

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

## G3.4.2 Cache identification

The ARMv8 cache identification consists of a set of registers that describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes cache maintenance instructions that:

- Affect the entire cache, for example [ICIALUIS](#).
- Operate by VA, for example [ICIMVAU](#).
- Operate by set/way, for example [DCISW](#).

The cache identification registers are:

- A single Cache Type Register, [CTR](#), that defines:
  - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  - The cache indexing and tagging policy of the Level 1 instruction cache.

### Note

It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see [System level caches on page G3-4547](#).

- A single Cache Level ID Register, [CLIDR](#), that defines:
  - The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
  - The *Level of Unification Inner Shareable* (LoUIS), *Level of Coherence* (LoC) and the *Level of Unification* (LoU) for the caches. See [Terms used in describing the cache maintenance instructions on page G3-4532](#) for a definition of these terms.
  - An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.
- A single Cache Size Selection Register, [CSSELR](#), that selects the cache level and cache type of the current Cache Size Identification Register.
- For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, [CCSIDR](#), that defines:
  - Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  - The number of sets, associativity and line length of the cache. See [Terms used in describing the cache maintenance instructions on page G3-4532](#) for a definition of these terms.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.

3. For each cache identified at stage 2:
  - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
    - An instruction cache.
    - A data or unified cache.
  - Read the Cache Size ID Register to find details of the cache.

### G3.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and is defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in [Memory types and attributes on page E2-2782](#), the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

In ARMv8, Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a *cache transient hint* is supported, see [Transient cacheability hint](#).

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hit is supported the following cache allocation hints can be used:

**For read accesses:** Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

**For write accesses:** Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

#### ———— Note ————

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.
- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.
- For VMSAv8-32 translation table walks using the Long-descriptor translation table format, the appropriate [TCR](#).{IRGN<sub>n</sub>, ORGN<sub>n</sub>} fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

### Transient cacheability hint

In ARMv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported for the VMSAv8-32 translation scheme when using the Long-descriptor translation table format. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

#### ———— Note ————

The architecture does not specify what is meant by a *relatively short period*.

When using the Short-descriptor translation table format, VMSAv8-32 cannot support the Transient hint.

The description of the [MAIR0](#), [MAIR1](#), [HMAIR0](#), and [HMAIR1](#) registers includes the assignment of the Transient attribute in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

### G3.4.4 Enabling and disabling the caching of memory accesses in AArch32 state

In ARMv8, Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

#### ———— Note ————

These Cacheability controls replace the cache enable controls provided in previous versions of the ARM architecture.

In AArch32 state, the Cacheability control fields and their effects are as follows:

#### For the Non-secure PL1&0 translation regime

The Non-secure instance of [SCTLR](#) holds the EL1 controls that affect cacheability:

- When the value of [SCTLR.C](#) is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the PL1&0 stage 1 translation tables are Non-cacheable.
- When the value of [SCTLR.I](#) is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of [HCR2.CD](#) is 1:
  - All stage 2 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the PL1&0 stage 2 translation tables are Non-cacheable.
- When the value of [HCR2.ID](#) is 1:
  - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of [HCR.DC](#) is 1, all Non-secure stage 1 translations and all accesses to the Non-secure EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of [SCTLR.C](#). This applies to translations for both data and instruction accesses.

In addition, when the value of [SCTLR.M](#) is 0, indicating that the stage 1 translations are disabled for the translation regime, then if EL2 is using AArch32 and the value of [HCR.DC](#) is 0 or if EL2 is using AArch64 and the value of [HCR\\_EL2.DC](#) is 0, then:

- If the value of [SCTLR.I](#) is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of [SCTLR.I](#) is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

---

**Note**

- In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in *Combining the Cacheability attribute on page G4-4626*.
  - The Non-secure **SCTLR**.{C, I} and **HCR**.DC fields have no effect on the Secure PL1&0 and EL2 translation regimes.
  - The **HCR2**.{ID, CD} fields affect only stage 2 of the Non-secure PL1&0 translation regime.
  - In Non-secure state, the PL1&0 translation regime can be described as the Non-secure EL1&0 translation regime. This is consistent with the equivalent AArch64 descriptions.
- 

**For the Secure PL1&0 translation regime**

The Secure instance of **SCTLR** holds the controls that determine cacheability:

- When the value of **SCTLR**.C is 0:
  - All data accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.
  - All accesses to the Secure PL1&0 translation tables are Non-cacheable.
- When the value of **SCTLR**.I is 0:
  - All instruction accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.

In addition, when the value of **SCTLR**.M is 0, indicating that stage 1 translations are disabled, then:

- If the value of **SCTLR**.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of **SCTLR**.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

---

**Note**

The Secure **SCTLR**.{I, C, M} fields have no effect on the Non-secure PL1&0 and EL2 translation regimes.

---

**For the EL2 translation regime**

- When the value of **HSCTLR**.C is 0:
  - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
  - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of **HSCTLR**.I is 0:
  - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

In addition, when the value of **HSCTLR**.M is 0, indicating that stage 1 translations are disabled, then:

- If the value of **HSCTLR**.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of **HSCTLR**.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

---

**Note**

The **HSCTLR**.{I, C, M} fields have no effect on the PL1&0 and EL3 translation regimes.

---

The effect of the **SCTLR**.C or **HSCTLR**.C and **HCR2**.CD bits is reflected in the result of the address translation instructions in the PAR.

---

**Note**

- The requirements in this section mean the architecturally required effects of [SCTLR.I](#) and [HSCTLR.I](#) are limited to their effects on caching instruction accesses in unified caches.
  - This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in [Mismatched memory attributes on page E2-2792](#) must be followed to manage the corresponding loss of coherency.
- 

### G3.4.5 Behavior of caches at reset

In ARMv8:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.
- The Cacheability control fields described in [Enabling and disabling the caching of memory accesses in AArch32 state on page G3-4529](#) reset to values that force all memory locations to be treated as Non-cacheable.

---

**Note**

This applies only to the controls that apply to the Translation regime that is used by the Exception level, PE mode, and Security state entered on reset.

---

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
  - Provide a mechanism to ensure the correct initialization of the caches.
  - Be documented clearly as part of the documentation of the device.In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.
- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

Similar rules apply to:

- Branch predictor behavior, see [Behavior of the branch predictors at reset on page G3-4539](#).
- TLB behavior, see [TLB behavior at reset on page G4-4629](#).

### G3.4.6 About cache maintenance in AArch32 state

The following sections give general information about cache maintenance in ARMv8:

- [Terms used in describing the cache maintenance instructions on page G3-4532](#).
- [The ARMv8 abstraction of the cache hierarchy on page G3-4534](#).

The following sections describe the AArch32 state cache maintenance instructions:

- [AArch32 instruction cache maintenance instructions \(IC\\*\) on page G3-4536](#).
- [AArch32 data cache maintenance instructions \(DC\\*\) on page G3-4537](#).

---

**Note**

Some descriptions of the cache maintenance instructions refer to the Cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the [SCTLR.{I, C}](#) controls.

---

## Terms used in describing the cache maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the virtual address of the memory location to be maintained, referred to as operating *by VA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches and branch predictors, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- [Terminology for cache maintenance instructions operating by set/way](#).
- [Terminology for Clean, Invalidate, and Clean and Invalidate instructions](#).

---

### Note

There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see [The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4567](#).

---

## Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

<b>Level</b>	<p>The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the <a href="#">CLIDR</a>.</p> <p>In the ARM architecture, the lower numbered cache levels are those closest to the PE. See <a href="#">Memory hierarchy on page E2-2772</a>.</p>
<b>Set</b>	<p>Each level of a cache is split up into a number of <i>sets</i>. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.</p> <p>In the ARM architecture, sets are numbered from 0.</p>
<b>Way</b>	<p>The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The <i>way</i> number specifies one of these locations.</p> <p>In the ARM architecture, ways are numbered from 0.</p>

---

### Note

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

---

## Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.
2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

**Clean** A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the Shareability domain of that memory location.

**Invalidate** A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

---

**Note**

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

---

### Clean and Invalidate

A cache *clean* and *invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- For instruction operating by VA, two conceptual points are defined:

#### Point of Coherency (PoC)

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

---

**Note**

The presence of system caches can affect the determination of the point of coherency as described in [System level caches on page G3-4547](#).

---

#### Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable Shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable Shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the [CLIDR](#) relate to these conceptual points:

#### **LoC, Level of Coherence**

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

#### **LoUU, Level of Unification, uniprocessor**

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

#### **LoUIS, Level of Unification, Inner Shareable**

In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see [CLIDR, Cache Level ID Register on page G6-4823](#).

### **The ARMv8 abstraction of the cache hierarchy**

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- [Cache maintenance instructions that operate by VA](#).
- [Cache maintenance instructions that operate by set/way on page G3-4535](#).

#### **Cache maintenance instructions that operate by VA**

The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See [Terms used in describing the cache maintenance instructions on page G3-4532](#) for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

[AArch32 cache and branch predictor maintenance instructions on page G3-4535](#) lists the VA-based maintenance instructions.

The [CTR](#) holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the **CTR** defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

#### Cache maintenance instructions that operate by set/way

*AArch32 cache and branch predictor maintenance instructions* lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

### G3.4.7 AArch32 cache and branch predictor maintenance instructions

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. [Table G3-3](#) shows the AArch32 system instructions. Instructions that take an argument include Rt in the instruction description.

AArch32 state also provides branch predictor maintenance instructions.

#### Note

- In [Table G3-3](#) the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.
- In AArch32 state, all of the maintenance instructions are available from EL1 or higher.
- In AArch64 state, branch predictors are always invisible to software, and therefore AArch64 state does not provide any branch predictor maintenance instructions.

**Table G3-3 AArch32 System instructions for cache maintenance**

Register	Instruction
Instruction cache maintenance instructions	
<a href="#">ICIALLUIS</a>	Invalidate all to Point of Unification, Inner Shareable
<a href="#">ICIALLU</a>	Invalidate all to Point of Unification
<a href="#">ICIMVAU</a> , Rt	Invalidate by virtual address to Point of Unification
Data cache maintenance instructions	
<a href="#">DCIMVAC</a> , Rt	Invalidate by virtual address to Point of Coherency
<a href="#">DCISW</a> , Rt	Invalidate by set/way
<a href="#">DCCMVAC</a> , Rt	Clean by virtual address to Point of Coherency
<a href="#">DCCSW</a> , Rt	Clean by set/way
<a href="#">DCCMVAU</a> , Rt	Clean by virtual address to Point of Unification
<a href="#">DCCIMVAC</a> , Rt	Clean and invalidate by virtual address to Point of Coherency
<a href="#">DCCISW</a> , Rt	Clean and invalidate by set/way

**Table G3-3 AArch32 System instructions for cache maintenance (continued)**

Register	Instruction
Branch prediction maintenance instructions	
<a href="#">BPIMVA</a> , Rt	Invalidate the virtual address from the branch predictors
<a href="#">BPIALLIS</a> , Rt	Invalidate all entries from branch predictors, Inner Shareable
<a href="#">BPIALL</a> , Rt	Invalidate all entries from branch predictors

A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

In an implementation where the branch predictors are architecturally invisible, the [BPIMVA](#), [BPIALLIS](#), and [BPIALL](#) instructions can execute as NOPs.

The following subsections give more information about these instructions:

- [AArch32 instruction cache maintenance instructions \(IC\\*\)](#).
- [AArch32 data cache maintenance instructions \(DC\\*\)](#) on page G3-4537.
- [Branch predictors](#) on page G3-4538.
- [General requirements for the scope of cache and branch predictor maintenance instructions](#) on page G3-4539.
- [Effects of instructions that operate by VA to the Point of Coherency](#) on page G3-4540.
- [Effects of instructions that operate by VA but not to the Point of Coherency](#) on page G3-4540.
- [Effects of All and set/way maintenance instructions](#) on page G3-4541.
- [Effects of virtualization and security on the AArch32 cache maintenance instructions](#) on page G3-4541.
- [Boundary conditions for cache maintenance instructions](#) on page G3-4543.
- [Ordering of cache and branch predictor maintenance instructions](#) on page G3-4543.
- [Performing cache maintenance instructions](#) on page G3-4545.

### **AArch32 instruction cache maintenance instructions (IC\*)**

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system *Address Space Identifier*, ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the *Virtual Machine Identifier*, VMID.

For an instruction cache maintenance instruction that operates by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault case described in [Stage 2 fault on a stage 1 translation table walk](#) on page G4-4656.

For more information about these possible faults on an instruction that operates by VA see [MMU faults in AArch32 state](#) on page G4-4657.

An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction.

See also [Ordering of cache and branch predictor maintenance instructions on page G3-4543](#).

## AArch32 data cache maintenance instructions (DC\*)

Data cache maintenance instructions that take a set/way/level argument take a 32-bit register.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see [Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-6107](#) or the instruction description.

**DCISW** instructions executed at EL1 perform a clean and invalidate, meaning they execute as a **DCCISW** instruction, if all of the following apply:

- EL2 is implemented.
- Either:
  - EL2 is using AArch32 and the value of **HCR.SWIO** is 1.
  - EL2 is using AArch64 and the value of **HCR\_EL2.SWIO** is 1.
- EL3 is not implemented, or either:
  - EL3 is using AArch32 and the value of **SCR.NS** is 1.
  - EL3 is using AArch64 and the value of **SCR\_EL3.NS** is 1.

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system *Address Space Identifier*, ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the *Virtual Machine Identifier*, VMID.

A data or unified cache maintenance instruction that operates by VA cannot generate a Data Abort exception for a Domain fault, and cannot generate a Data Abort exception for a Permission fault, except for the Permission fault described in [Stage 2 fault on a stage 1 translation table walk on page G4-4656](#).

For more information about the possible faults on an instruction that operates by VA see [MMU faults in AArch32 state on page G4-4657](#).

**DCIMVAC** and **DCISW** instructions executed at EL1 perform a clean and invalidate, meaning they execute as a **DCCIMVAC** or **DCCISW** instruction, if all of the following apply:

- EL2 is implemented.
- PL1&0 stage two address translation is enabled, meaning either:
  - EL2 is using AArch32 and the value of **HCR.VM** is 1.
  - EL2 is using AArch64 and the value of **HCR\_EL2.VM** is 1.
- EL3 is not implemented, or either:
  - EL3 is using AArch32 and the value of **SCR.NS** is 1.
  - EL3 is using AArch64 and the value of **SCR\_EL3.NS** is 1.

If a memory fault that sets FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

See also [Ordering of cache and branch predictor maintenance instructions on page G3-4543](#).

## Branch predictors

In AArch32 state it is IMPLEMENTATION DEFINED whether branch prediction is architecturally visible. This means that under some circumstances software must perform branch predictor maintenance to avoid incorrect execution caused by out-of-date entries in the branch predictor. For example, to ensure correct operation it might be necessary to invalidate branch predictor entries on a change to instruction memory, or a change of instruction address mapping. For more information, see [Specific requirements for branch predictor maintenance instructions](#).

In an implementation where the branch predictors are architecturally invisible, the branch predictor maintenance instructions can execute as NOPs.

An invalidate all operation on the branch predictor ensures that any location held in the branch predictor has no functional effect on execution. An invalidate branch predictor by VA instruction operates on the address of the branch instruction, but can affect other branch predictor entries.

### ———— Note ————

The architecture does not make visible the range of addresses in a branch predictor to which the invalidate operation applies. This means the address used in the invalidate by VA operation must be the address of the branch to be invalidated.

If branch prediction is architecturally visible, an instruction cache invalidate all operation also invalidates all branch predictors.

See also [Ordering of cache and branch predictor maintenance instructions on page G3-4543](#).

### Specific requirements for branch predictor maintenance instructions

If, for a given translation regime and a given ASID and VMID as appropriate, the instructions at any virtual address change, then branch predictor maintenance instructions must be performed to invalidate entries in the branch predictor, to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- For any translation regime other than the Non-secure PL1&0 translation regime, enabling or disabling stage 1 translations.
- For the Non-secure PL1&0 translation regime:
  - When stage 2 translations are enabled, enabling or disabling stage 1 translations unless accompanied by a change of VMID.
  - When stage 2 translations are disabled, enabling or disabling stage 1 translations.
  - Enabling or disabling stage 2 translations.
- Writing new mappings to the translation tables.
- Any change to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers, unless:
  - For a change to the Secure PL1&0 translation regime, the change is accompanied by a change to the ASID.
  - For a change to the stage 1 translations of the Non-secure PL1&0 translation regime, the change is accompanied by a change to the ASID or a change to the VMID.
- Any change to the [VTTBR](#) or [VTCR](#) registers, unless accompanied by a change to the VMID.

---

**Note**

---

Invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged throughout the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates an MMU fault.
  - Changing a translation that generates an MMU fault to a valid translation.
- 

Failure to invalidate entries might give CONSTRAINED UNPREDICTABLE results, caused by the execution of old branches. For more information, see [Ordering of cache and branch predictor maintenance instructions on page G3-4543](#).

---

**Note**

---

- In ARMv8, there is no requirement to use the branch predictor maintenance operations to invalidate the branch predictor after:
    - Changing the ContextID or VMID.
    - A cache maintenance instruction that is identified as also flushing the branch predictors, see [AArch32 cache and branch predictor maintenance instructions on page G3-4535](#).
- 

[Cache maintenance instructions, functional group on page G4-4734](#) shows the branch predictor maintenance operations in a VMSA implementation.

### **Behavior of the branch predictors at reset**

In AArch32 state:

- If branch predictors are not architecturally invisible:
  - The branch predictors reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
  - The branch predictors are disabled at reset.
- An implementation can require the use of a specific branch predictor initialization routine to invalidate the branch predictor storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, but the routine must be documented clearly as part of the documentation of the device.
- ARM recommends that whenever an invalidation routine is required, it is based on the AArch32 branch predictor maintenance operations.

Similar rules apply:

- To cache behavior, see [Behavior of caches at reset on page G3-4531](#).
- To TLB behavior, see [TLB behavior at reset on page G4-4629](#).

### **General requirements for the scope of cache and branch predictor maintenance instructions**

The ARMv8 specification of the cache maintenance and branch predictor instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in [General behavior of the caches on page G3-4525](#), [Behavior of caches at reset on page G3-4531](#), and [Preloading caches on page E2-2775](#).

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

As a side-effect of a branch predictor maintenance instruction, any entry in the branch predictor might be invalidated.

———— **Note** ————

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

### Effects of instructions that operate by VA to the Point of Coherency

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the Shareability domain described by the Shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable Shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

**Table G3-4 PEs affected by cache maintenance instructions to the Point of Coherency**

Shareability	PEs affected	Effective to
Non-shareable	The PE performing the operation	The Point of Coherency of the entire system
Inner Shareable	All PEs in the same Inner Shareable Shareability domain as the PE performing the operation	The Point of Coherency of the entire system
Outer Shareable	All PEs in the same Outer Shareable Shareability domain as the PE performing the operation	The Point of Coherency of the entire system

### Effects of instructions that operate by VA but not to the Point of Coherency

The following instruction operate by VA but not to the Point of Coherency:

- Clean data or unified cache line by MVA to the Point of Unification, [DCCMVAU](#).
- Invalidate instruction cache line by MVA to Point of Unification, [ICIMVAU](#).
- Invalidate by MVA from branch predictors, [BPIMVA](#).

For these instructions, [Table G3-5](#) shows how, for a VA in a Normal or Device memory location, the Shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

**Table G3-5 PEs affected by cache maintenance instructions to the Point of Unification**

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction
Inner Shareable or Outer Shareable	All PEs in the same Inner Shareable Shareability domain as the PE executing the instruction	The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain as the PE executing the instruction

———— **Note** ————

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable Shareability domain containing the PE executing the instruction.

## Effects of All and set/way maintenance instructions

The [ICIALLU](#), [BPIALL](#) and DC\* set/way instructions apply only to the caches and branch predictors of the PE that performs the instruction. If the branch predictors are architecturally-visible, [ICIALLU](#) also performs a [BPIALL](#) operation.

The [ICIALLUIS](#) and [BPIALLIS](#) instructions can affect the caches and branch predictors of all PEs in the same Inner Shareable Shareability domain as the PE that performs the instruction. If the branch predictors are architecturally-visible, [ICIALLUIS](#) also performs a [BPIALLIS](#) operation. These instructions have an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain.

### ————— Note —————

The possible presence of system caches, as described in [System level caches on page G3-4547](#), means architecture does not guarantee that all levels of cache can be maintained using set/way instructions.

## Effects of virtualization and security on the AArch32 cache maintenance instructions

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance and branch predictor instructions performed in Non-secure state have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

[Table G3-6](#) shows the effects of virtualization and security on these maintenance instructions.

**Table G3-6 Effects of virtualization and security on the AArch32 cache maintenance instructions**

Cache maintenance instructions	Security state	Specified entry
Data or unified cache maintenance instructions		
Invalidate, Clean, or Clean and Invalidate by VA: <a href="#">DCIMVAC</a> , <a href="#">DCCMVAC</a> , <a href="#">DCCMVAU</a> , <a href="#">DCCIMVAC</a>	Either	All lines that hold the PA that, in the current translation regime, are mapped to by the combination of all of: <ul style="list-style-type: none"> <li>• The specified VA.</li> <li>• For an instruction executed at EL1, the current ASID if the location is mapped to by a non-global page.</li> <li>• For an instruction executed at Non-secure EL1, the current VMID<sup>a</sup>.</li> </ul>
Invalidate, Clean, or Clean and Invalidate by set/way: <a href="#">DCISW</a> , <a href="#">DCCSW</a> , <a href="#">DCCISW</a>	Non- secure	Line specified by set/way provided that the entry comes from the Non-secure PA space.
	Secure	Line specified by set/way regardless of the PA space that the entry has come from.

**Table G3-6 Effects of virtualization and security on the AArch32 cache maintenance instructions (continued)**

Cache maintenance instructions	Security state	Specified entry
Instruction cache maintenance instructions		
Invalidate by VA: <a href="#">ICIMVAU</a>	Either	<p>All lines corresponding to the specified VA<sup>b</sup> in the current translation regime and:</p> <ul style="list-style-type: none"> <li>For an instruction executed at EL1 or EL0, the current ASID.</li> <li>For an instruction executed at Non-secure EL1 or Non-secure EL0, the current VMID<sup>a</sup>.</li> </ul>
Invalidate All: <a href="#">ICIALLU</a> , <a href="#">ICIALUIS</a>		<ul style="list-style-type: none"> <li>Can invalidate any unlocked entry in the instruction cache.</li> <li>Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information:</li> </ul> <p><b>Non-secure</b></p> <p>An instruction executed at EL1 must operate on all instruction cache lines that contain entries associated with the current virtual machine, meaning any entry with the current VMID.<sup>a</sup></p> <p>An instruction executed at EL2 must operate on all instruction cache lines that contain entries that can be accessed from Non-secure state.</p> <p><b>Secure</b></p> <p>The instruction must invalidate all instruction cache lines.</p>
Branch predictor instructions <sup>c</sup>		
Invalidate by VA: <a href="#">BPIMVA</a>	Either	<p>All lines that, in the current translation regime, are mapped to by the combination of: all of:</p> <ul style="list-style-type: none"> <li>The specified VA.</li> <li>For an instruction executed at EL1 or EL0, the current ASID if the location is mapped to by a non-global page.</li> <li>For an instruction executed at Non-secure EL1 or EL0, the current VMID<sup>a</sup>.</li> </ul>
Invalidate all: <a href="#">BPIALL</a> , <a href="#">BPIALLIS</a>		<ul style="list-style-type: none"> <li>Can invalidate any unlocked entry in the branch predictor.</li> <li>Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information.</li> </ul>

a. Dependencies on the VMID apply even when [HCR\\_EL2.VM](#) is set to 0. However, [VTTBR\\_EL2.VMID](#) resets to zero, meaning there is a valid VMID from reset.

b. The type of instruction cache used affects the interpretation of the specified entries in this table such that:

- For a PIPT instruction cache, the cache maintenance applies to all entries whose physical address corresponds to the specified address.
- For a VIPT instruction cache, the cache maintenance applies to entries whose virtual index and physical tag corresponds to the specified address.

For information of types of instruction cache, see [Instruction caches on page G4-4647](#).

c. In an implementation where the branch predictors are architecturally invisible, these instructions can execute as NOPs.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in [The interaction of cache lockdown with cache maintenance instructions on page G3-4546](#) applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way instructions can, instead, perform a clean and invalidate by set/way.

- The AArch32 Data cache invalidate instructions **DCIMVAC** and **DCISW**, perform a cache clean as well as a cache invalidate, meaning **DCIMVAC** performs the same invalidation as a **DCCIMVAC** instruction, and **DCISW** performs the same invalidation as a **DCCISW** instruction, if both of the following apply:
  - The value of **HCR.VM** is 1.
  - The instruction is executed in Non-secure state, or EL3 is not implemented.
- The AArch32 Data cache invalidate by set/way instruction **DCISW** performs a cache clean as well as a cache invalidate, meaning it performs the same invalidation as a **DCCISW** instruction, if both of the following apply:
  - The value of **HCR.SWIO** is 1.
  - The instruction is executed in Non-secure state, or EL3 is not implemented.
- When the value of **HCR.FB** is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch32, this applies to the **TLBIMVA**, **TLBIASID**, **TLBIMVAA**, **TLBIMVAL**, **TLBIMVAAL**, and **ICIALLU** instructions. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction, for example **ICIALLU** performs the invalidation that would be performed by **ICIALLUIS**, and **BPIALL** performs the invalidation that would be performed by **BPIALLIS**.

For more information about the cache maintenance instructions, see [About cache maintenance in AArch32 state on page G3-4531](#), [AArch32 cache and branch predictor maintenance instructions on page G3-4535](#), and [Chapter G4 The AArch32 Virtual Memory System Architecture](#).

## Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  - Is Normal memory or Device memory.
  - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

## Ordering of cache and branch predictor maintenance instructions

The following rules describe the effect of the memory order model on the cache and branch predictor maintenance instructions:

- All cache and branch predictor maintenance instructions that do not specify an address execute, relative to each other, in program order.  
All cache and branch predictor instructions that specify an address:
  - Execute in program order relative to all cache and branch predictor operations that do not specify an address.
  - Execute in program order relative to all cache and branch predictor operations that specify the same address.
  - Can execute in any order relative to cache and branch predictor operations that specify a different address.
- Where a cache maintenance or branch predictor instruction appears in program order before a change to the translation tables, the architecture guarantees that the cache or branch predictor maintenance instruction uses the translations that were visible before the change to the translation tables.

- Where a change of the translation tables appears in program order before a cache maintenance or branch predictor instruction, software must execute the sequence outlined in [Ordering and completion of TLB maintenance instructions on page G4-4635](#) before performing the cache or branch predictor maintenance instruction, to ensure that the maintenance operation uses the new translations.
- A DMB instruction causes the effect of all data or unified cache maintenance instructions appearing in program order before the DMB to be visible to all explicit load and store operations appearing in program order after the DMB.  
  
Also, a DMB instruction ensures that the effects of any data or unified cache maintenance instruction appearing in program order before the DMB are observable by any observer in the same required Shareability domain before any data or unified cache maintenance or explicit memory operations appearing in program order after the DMB are observed by the same observer. Completion of the DMB does not guarantee the visibility of all data to other observers. For example, all data might not be visible to a translation table walk, or to instruction fetches.
- A DSB is required to guarantee the completion of all cache maintenance instruction that appear in program order before the DSB instruction.
- A [Context synchronization event](#) is required to guarantee the effects of any branch predictor maintenance operation. This means a [Context synchronization event](#) causes the effect of all completed branch predictor maintenance operations appearing in program order before the [Context synchronization event](#) to be visible to all instructions after the [Context synchronization event](#).  
  
This means that, if a branch instruction appears after an invalidate branch predictor operation and before any [Context synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the branch instruction is affected by the invalidate. Software must avoid this ordering of instructions, because it might cause CONSTRAINED UNPREDICTABLE behavior.
- Any data or unified cache maintenance instruction by VA must be executed in program order relative to any explicit load or store on the same PE to an address covered by the VA of the cache instruction if that load or store is to Normal Cacheable memory. The order of memory accesses that result from the cache maintenance instruction, relative to any other memory accesses to Normal Cacheable memory, are subject to the memory ordering rules. For more information, see [Definition of the ARMv8 memory model on page E2-2762](#).  
  
Any data or unified cache maintenance instruction by VA can be executed in any order relative to any explicit load or store on the same PE to an address covered by the VA of the cache maintenance instruction if that load or store is not to Normal Cacheable memory.
- There is no restriction on the ordering of data or unified cache maintenance instruction by VA relative to any explicit load or store on the same PE where the address of the explicit load or store is not covered by the VA of the cache instruction. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.
- There is no restriction on the ordering of a data or unified cache maintenance instruction by set/way relative to any explicit load or store on the same PE. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.
- Software must execute a [Context synchronization event](#) after the completion of an instruction cache maintenance instruction, to guarantee that the effect of the maintenance instruction is visible to any instruction fetch.

A DSB or DMB instruction intended to ensure the completion of cache maintenance instructions or branch predictor instructions must have an access type of both loads and stores.

The scope of instruction cache maintenance depends on the type of the instruction cache. For more information see [Instruction caches on page G4-4647](#).

### Example G3-1 Cache cleaning operations for self-modifying code

The sequence of cache cleaning operations for a line of self-modifying code on a uniprocessor system is:

; Coherency example for data and instruction accesses within the same Inner Shareable domain.

; Enter this code with <Rt> containing a new 32-bit instruction,  
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line  
; instead of STR for a 16-bit instruction.

```
STR Rt, [Rn]
DCCMVAU Rn      ; Clean data cache by MVA to point of unification (PoU)
DSB              ; Ensure visibility of the data cleaned from cache
ICIMVAU Rn      ; Invalidate instruction cache by MVA to PoU
BPIMVA Rn       ; Invalidate branch predictor by MVA to PoU
DSB              ; Ensure completion of the invalidations
ISB              ; Synchronize the fetched instruction stream
```

## Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the [CTR.DMinLine](#) value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the [CTR.IMinLine](#) value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

### Example code for cache maintenance instructions

The cache maintenance instructions by set/way can be used to clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

#### ———— Note ————

Because the set/way instructions operate only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Because any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the cache line is not affected by set/way based cache maintenance. Therefore, ARM strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

[System level caches on page G3-4547](#) refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency.

```
MRC p15, 1, R0, c0, c0, 1 ; Read CLIDR into R0
ANDS R3, R0, #0x07000000
MOV R3, R3, LSR #23        ; Cache level value (naturally aligned)
BEQ Finished
MOV R10, #0
Loop1
```

```

    ADD R2, R10, R10, LSR #1    ; Work out 3 x cache level
    MOV R1, R0, LSR R2          ; bottom 3 bits are the Cache type for this level
    AND R1, R1, #7              ; get those 3 bits alone
    CMP R1, #2
    BLT Skip                    ; no cache or only instruction cache at this level
    MCR p15, 2, R10, c0, c0, 0 ; write CSSELR from R10
    ISB                          ; ISB to sync the change to the CCSIDR
    MRC p15, 1, R1, c0, c0, 0   ; read current CCSIDR to R1
    AND R2, R1, #7              ; extract the line length field
    ADD R2, R2, #4               ; add 4 for the line length offset (log2 16 bytes)
    MOV R4, #0x3FF
    ANDS R4, R4, R1, LSR #3      ; R4 is the max number on the way size (right aligned)
    CLZ R5, R4                  ; R5 is the bit position of the way size increment
    MOV R9, R4                  ; R9 working copy of the max way size (right aligned)
Loop2
    MOV R7, #0x00007FFF
    ANDS R7, R7, R1, LSR #13    ; R7 is the max number of the index size (right aligned)
Loop3
    ORR R11, R10, R9, LSL R5    ; factor in the way number and cache number into R11
    ORR R11, R11, R7, LSL R2    ; factor in the index number
    MCR p15, 0, R11, c7, c10, 2 ; DCCSW, clean by set/way
    SUBS R7, R7, #1             ; decrement the index
    BGE Loop3
    SUBS R9, R9, #1             ; decrement the way number
    BGE Loop2
Skip
    ADD R10, R10, #2            ; increment the cache number
    CMP R3, R10
    DSB                          ; ensure completion of previous cache maintenance instruction
    BGT Loop1
Finished

```

Similar approaches can be used for all cache maintenance instructions.

### G3.4.8 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

#### The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, [DCCSW](#).
  - Cache invalidate by set/way, [DCISW](#).
  - Cache clean and invalidate by set/way, [DCISW](#).
  - Instruction cache invalidate all, [ICIALLU](#) and [ICIALUIS](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.

3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See [Data Abort exception on page G1-4387](#).

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, [DCCMVAC](#) and [DCCMVAU](#).
- Cache invalidate by virtual address, [DCIMVAC](#).
- Cache clean and invalidate by virtual address, [DCCIMVAC](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See [DFSR](#) or [HSR](#).

In an implementation that includes EL2, if [HCR.TIDCP](#) is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

#### ———— **Note** ————

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

#### **Additional cache functions for the implementation of lockdown**

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED space. See [IMPLEMENTATION DEFINED registers, functional group on page G4-4744](#).

### **G3.4.9 System level caches**

The ARM Architecture defines a *system cache* as a cache that is not described in the PE Cache Identification registers, [CCSIDR](#) and [CLIDR](#), and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.

2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entire system cache must be performed, as is the case for power management, it must be performed using non-architectural mechanisms.
3. System caches which lie beyond the point of coherency and so are invisible to software. The management of such caches is outside the scope of architecture.

## G3.5 System register support for IMPLEMENTATION DEFINED memory features

The VMSAv8-32 defines the following registers for describing IMPLEMENTATION DEFINED features of the memory system:

- The TCM Type Register, [TCMTR](#) must be implemented. The following conditions apply to this register:
  - If no TCMs are implemented, the [TCMTR](#) indicates zero-size TCMs.
  - If bits[31:29] are 0b100, the format of the rest of the register is IMPLEMENTATION DEFINED. This value indicates that the implementation includes TCMs that do not follow the legacy usage model. Other fields in the register might give more information about the TCMs.
- The System register encoding space with {coproc==0b1111, CRn==c9, CRm=={c0-c2, c5-c7}} is IMPLEMENTATION DEFINED for all values of opc2 and opc1. This space is reserved for branch predictor, cache and TCM functionality, for example maintenance, override behaviors and lockdown.
- In a VMSAv8-32 implementation, part of the System register encoding space with {coproc==0b1111, CRn==c10} is IMPLEMENTATION DEFINED and reserved for TLB functionality, see [TLB lockdown on page G4-4630](#).
- The System register encoding space with {coproc==0b1111, CRn==c11, CRm=={c0-c8, c15}} is IMPLEMENTATION DEFINED for all values of opc2 and opc1. This space is reserved for DMA operations to and from the TCMs.

In addition, the System register encoding space with {coproc==0b1111, CRn==c15} is reserved for IMPLEMENTATION DEFINED registers, and can provide additional registers for the memory system. For more information, see [Reserved encodings in the VMSAv8-32 System register \(coproc==0b1111\) space on page G4-4709](#).

## G3.6 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or Debug hardware. External aborts include parity or ECC errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 memory structure might generate an external abort.

An external abort is one of:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see [Exception terminology on page G1-4310](#).

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous external aborts.

VMSAv8-32 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous. The reported fault code identifies whether the external abort is synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported. Asynchronous external aborts are taken as SError interrupt exceptions.

In AArch32 state:

- SError interrupts are taken as asynchronous Data Abort exceptions.
- Synchronous external aborts:
  - On data accesses are taken as synchronous Data Abort exceptions.
  - On instruction fetches, or prefetches, are taken as synchronous Prefetch Abort exceptions.

See also:

- [External abort on a translation table walk on page G4-4659](#).
- [Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340](#).

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running. ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:

- [External abort on instruction fetch](#).
- [External abort on data read or write](#).
- [Provision for classification of external aborts on page G3-4551](#).
- [Parity or ECC error reporting on page G3-4551](#).

The section [Exception reporting in a VMSAv8-32 implementation on page G4-4663](#) describes the reporting of external aborts.

### G3.6.1 External abort on instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous. A synchronous external abort on an instruction fetch is taken precisely.

An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when `PSTATE.A` is set to 1, otherwise they are reported using the Data Abort exception.

### G3.6.2 External abort on data read or write

Externally-generated errors during a data read or write can be either synchronous or asynchronous.

An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when [PSTATE.A](#) is set to 1, otherwise they are reported using the Data Abort exception.

### G3.6.3 Provision for classification of external aborts

For a synchronous external abort taken to a privileged mode other than Hyp mode, an implementation can use the [DFSR.ExT](#) and [IFSR.ExT](#) bits to provide more information about synchronous external aborts:

- [DFSR.ExT](#) provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on data accesses.
- [IFSR.ExT](#) provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on instruction accesses.

For a synchronous external abort taken to Hyp mode, the [HSR.EA](#), ISS[9] bit, provides an IMPLEMENTATION DEFINED classification of external aborts.

For all aborts other than synchronous external aborts these bits return a value of 0.

### G3.6.4 Parity or ECC error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache systems. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see [Exception reporting in a VMSAv8-32 implementation on page G4-4663](#). However when parity or ECC error reporting is implemented it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code, or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as external aborts.

## G3.7 Memory barrier instructions

[Memory barriers on page E2-2768](#) describes the memory barrier instructions. This section describes the system level controls of those instructions.

### G3.7.1 EL2 control of the Shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 and supports Shareability limitations on the data barrier instructions, the [HCR.BSU](#) field can modify the required Shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. [Table G3-7](#) shows the encoding of this field:

**Table G3-7 EL2 control of Shareability of barrier instructions executed at EL0 or EL1**

<a href="#">HCR.BSU</a>	Minimum Shareability of barrier instructions
00	No effect, Shareability is as specified by the instruction
01	Inner Shareable
10	Outer Shareable
11	Full system

For an instruction executed at EL0 or EL1 in Non-secure state, [Table G3-8](#) shows how the [HCR.BSU](#) is combined with the Shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction:

**Table G3-8 Effect of the HCR\_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL1**

Shareability specified by the DMB or DSB argument	<a href="#">HCR.BSU</a>	Resultant Shareability
Full system	Any	Full system
Outer Shareable	00, 01, or 10	Outer Shareable
	11, Full system	Full system
Inner Shareable	00 or 01	Inner Shareable
	10, Outer Shareable	Outer Shareable
	11, Full system	Full system
Non-shareable	00, No effect	Non-shareable
	01, Inner Shareable	Inner Shareable
	10, Outer Shareable	Outer Shareable
	11, Full system	Full system

## G3.8 Pseudocode description of general memory system instructions

This section lists the pseudocode describing general memory operations:

- [Memory data type definitions](#).
- [Basic memory access](#).
- [Aligned memory access](#) on page G3-4554.
- [Unaligned memory access](#) on page G3-4554.
- [Exclusives monitors operations](#) on page G3-4554.
- [Access permission checking](#) on page G3-4555.
- [Abort exceptions](#) on page G3-4555.
- [Memory barriers](#) on page G3-4555.

### G3.8.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the [AddressDescriptor](#) type.
- Full address, defined by the [FullAddress](#) type.
- Memory attributes, defined by the [MemoryAttributes](#) type.
- Memory type, defined by the [MemType](#) enumeration.
- Device memory type, defined by the [DeviceType](#) enumeration.
- Normal memory attributes, defined by the [MemAttrHints](#) type.
- Cacheability attributes, defined by the [MemAttr\\_NC](#), [MemAttr\\_WT](#), and [MemAttr\\_WB](#) constants.
- Allocation hints, defined by the [MemHint\\_No](#), [MemHint\\_WA](#), [MemHint\\_RA](#), and [MemHint\\_RWA](#) constants.
- Access permissions, defined by the [Permissions](#) type.

### G3.8.2 Basic memory access

The two forms of the `_Mem[]` accessor, non-assignment (memory read) `_Mem[]` and assignment (memory write) `_Mem[]`, are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The functions address the array using `desc.paddress`, that supplies:

- The physical address.
- An NS bit that selects between the Secure and Non-secure parts of the array.

The attributes in `desc.memattrs` are used by the memory system to determine caching and ordering behaviors as described in [Memory types and attributes](#) on page E2-2782, [Definition of the ARMv8 memory model](#) on page E2-2762, and [Atomicity in the ARM architecture](#) on page E2-2758.

An additional parameter to the `_Mem[]` accessor defines the access type, for example normal, exclusive, or ordered, and whether the access is made as part of a translation table walk.

The actual implemented array of memory might be smaller than the maximum address size that can be accessed from AArch32 state. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

`PAMax()` returns the IMPLEMENTATION DEFINED size of the physical address.

#### ————— **Note** —————

A stage of address translation using VMSAv8-32 cannot generate an output address of more than 40 bits.

### G3.8.3 Aligned memory access

The `AArch32.MemSingle[]` functions make atomic, little-endian accesses of size bytes.

### G3.8.4 Unaligned memory access

See *Unaligned data access on page E2-2777* for details of the `SCTLR.A` and `HSCTLR.A` controls on the generation of alignment faults. The `HSCTLR` control applies to Normal memory accesses from Hyp mode, and the `SCTLR` control applies to Normal memory accesses from all other modes.

The `Mem_with_type[]` functions make an access of the required type. If that access is naturally aligned, each form of the function performs an atomic access by making a single call to `AArch32.MemSingle[]`. If that access is not aligned but passes the `AArch32.CheckAlignment()` checks, each form of the function synthesizes the required access from multiple calls to `AArch32.MemSingle[]`. It also reverses the byte order if the access is big-endian.

### G3.8.5 Exclusives monitors operations

The `AArch32.SetExclusiveMonitors()` function sets the Exclusives monitors for a Load-Exclusive instruction, for a block of bytes. The size of the blocks is determined by `size`, at the VA address. The `ExclusiveMonitorsPass()` function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors and therefore completes successfully.

The `AArch32.ExclusiveMonitorsPass()` function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors, by checking whether the Exclusives monitors are set to include the location of the memory block specified by `size`, at the virtual address defined by `address`. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return `FALSE` if the virtual address is not the same as that used in the previous call to `AArch32.SetExclusiveMonitors()`.

The `ExclusiveMonitorsStatus()` function returns 0 if the previous atomic write was to the same physical memory locations selected by `ExclusiveMonitorsPass()` and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The `MarkExclusiveGlobal()` procedure takes as arguments a `FullAddress.paddress`, the PE identifier `processorid` and the size of the transfer. The procedure records that the PE `processorid` has requested exclusive access covering at least `size` bytes from address `paddress`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The `MarkExclusiveLocal()` procedure takes as arguments a `FullAddress.paddress`, the PE identifier `processorid` and the size of the transfer. The procedure records in a local record that PE `processorid` has requested exclusive access to an address covering at least `size` bytes from address `paddress`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

The `IsExclusiveGlobal()` function takes as arguments a `FullAddress.paddress`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether it returns `TRUE` or `FALSE` if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns `FALSE`.

The `IsExclusiveLocal()` function takes as arguments a `FullAddress.paddress`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked an address range as exclusive access requested that covers at least the `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether this function returns `TRUE` or `FALSE` if the address marked as exclusive access requested does not cover all of `size` bytes from address `paddress`. If no address is marked as exclusive access requested, then this function returns `FALSE`. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of size bytes starting from `paddress` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of size bytes starting from `paddress` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

### G3.8.6 Access permission checking

The function `AArch32.CheckPermission()` is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors.

The interpretation of access permission is shown in *Memory access control* on page G4-4605.

### G3.8.7 Abort exceptions

The function `AArch32.Abort()` generates a Data Abort exception or a Prefetch Abort exception by calling the `AArch32.TakeDataAbortException()` or `AArch32.TakePrefetchAbortException()` function.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. *Pseudocode description of VMSAv8-32 memory system operations* on page G4-4748 provides a number of wrappers to generate a `FaultRecord`.

The function `AArch32.NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a `FaultRecord` contains a fault.

### G3.8.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations `MBReqDomain` and `MBReqTypes`.

These enumerations define the required Shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures `DataMemoryBarrier()`, `DataSynchronizationBarrier()`, and `InstructionSynchronizationBarrier()` perform the memory barriers.

# Chapter G4

## The AArch32 Virtual Memory System Architecture

This chapter describes the ARMv8-A AArch32 Virtual Memory System Architecture (VMSA), that is backwards-compatible with VMSAv7. It includes the following sections:

- *About VMSAv8-32 on page G4-4558.*
- *The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4567.*
- *Translation tables on page G4-4571.*
- *The VMSAv8-32 Short-descriptor translation table format on page G4-4576.*
- *The VMSAv8-32 Long-descriptor translation table format on page G4-4585.*
- *Memory access control on page G4-4605.*
- *Memory region attributes on page G4-4616.*
- *Translation Lookaside Buffers (TLBs) on page G4-4628.*
- *TLB maintenance requirements on page G4-4632.*
- *Caches in VMSAv8-32 on page G4-4646.*
- *VMSAv8-32 memory aborts on page G4-4649.*
- *Exception reporting in a VMSAv8-32 implementation on page G4-4663.*
- *Address translation instructions on page G4-4682.*
- *About the System registers for VMSAv8-32 on page G4-4689.*
- *VMSAv8-32 organization of registers in the (coproc == 0b1110) encoding space on page G4-4704.*
- *VMSAv8-32 organization of registers in the (coproc == 0b1111) encoding space on page G4-4707.*
- *Functional grouping of VMSAv8-32 System registers on page G4-4726.*
- *Pseudocode description of VMSAv8-32 memory system operations on page G4-4748.*

---

### Note

This chapter must be read with [Chapter G3 The AArch32 System Level Memory Model](#).

---

## G4.1 About VMSAv8-32

---

### Note

---

- This chapter describes the ARMv8 VMSA for AArch32 state, VMSAv8-32. This is generally equivalent to VMSAv7 for an implementation that includes all of the Security Extensions, the Multiprocessing Extensions, the Large Physical Address Extension, and the Virtualization Extensions.
- This chapter describes the control of the VMSA by Exception levels that are using AArch32. [Security state, Exception levels, and AArch32 execution privilege on page G1-4318](#) summarizes how the AArch32 PE modes map onto the Exception levels.  
[Chapter D4 The AArch64 Virtual Memory System Architecture](#) describes the control of the VMSA by Exception levels that are using AArch64.
- For details of the VMSA differences in previous versions of the ARM architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

The main function of the VMSA is to perform address translation, and access permissions and memory attribute determination and checking, for memory accesses made by the PE. Address translation, and permissions and attribute determination and checking, is performed by a *stage* of address translation.

In VMSAv8-32, the *Memory Management Unit* (MMU) provides a number of stages of address translation. This chapter describes only the stages that are visible from Exception levels that are using AArch32, which are as follows:

#### For operation in Secure state

A single stage of address translation, for use when executing at PL1 or PL0. This is the *Secure PL1&0 stage 1* address translation stage.

#### For operation in Non-secure state

- A single stage of address translation for use when executing at PL2. This is the *Non-secure PL2 stage 1* address translation stage.
- Two stages of address translation for use when executing at PL1 or PL0. These are:
  - The *Non-secure PL1&0 stage 1* address translation stage.
  - The *Non-secure PL1&0 stage 2* address translation stage.

The System registers provide independent control of each supported stage of address translation, including a control to disable that stage of translation.

However, if the PE is executing at EL0 using AArch32 when EL1 is using AArch64 then it is using the VMSAv8-64 EL1&0 translation regime, described in [Chapter D4 The AArch64 Virtual Memory System Architecture](#).

These features mean the VMSAv8-32 can support a hierarchy of software supervision, for example an Operating System and a hypervisor.

Each stage of address translation uses address translations and associated memory properties held in memory mapped tables called *translation tables*.

For information about how the MMU features differ if an implementation does not include all of the Exception levels, see [About address translation for VMSAv8-32 on page G4-4562](#).

The translation tables define the following properties:

#### Access to the Secure or Non-secure address map

The translation table entries determine whether an access from Secure state accesses the Secure or the Non-secure address map. Any access from Non-secure state accesses the Non-secure address map.

### Memory access permission control

This controls whether a program is permitted to access a memory region. For instruction and data access, the possible settings are:

- No access.
- Read-only.
- Write-only. This is possible only in a translation regime with two stages of translation.
- Read/write.

For instruction accesses, additional controls determine whether instructions can be fetched and executed from the memory region.

If a PE attempts an access that is not permitted, a memory fault is signaled to the PE.

### Memory region attributes

These describe the properties of a memory region. The top-level attribute, the Memory type, is one of Normal, or a type of Device memory, as follows:

- Both translation table formats support the following Device memory types:
  - Device-nGnRnE
  - Device-nGnRE
- The Long-descriptor translation table format supports, in addition, the following Device memory types:
  - Device-nGRE
  - Device-GRE

#### Note

ARMv8 added the Device-nGRE and Device-GRE memory types. Also, in versions of the ARM architecture before ARMv8:

- Device-nGnRnE memory is described as Strongly-ordered memory.
- Device-nGnRE memory is described as Device memory.

Normal memory regions can have additional attributes.

For more information, see [Memory types and attributes on page E2-2782](#).

### Address translation mappings

An address translation maps an *input address* to an *output address*.

A stage 1 translation takes the address of an explicit data access or instruction fetch, a *virtual address* (VA), as the input address, and translates it to a different output address:

- If only one stage of translation is provided, this output address is the *physical address* (PA).
- If two stages of address translation are provided, the output address of the stage 1 translation is an *intermediate physical address* (IPA).

#### Note

In the ARMv8-32 architecture, a software agent, such as an Operating System, that uses or defines stage 1 memory translations, might be unaware of the distinction between IPA and PA.

A stage 2 translation translates the IPA to a PA.

The possible Security states and privilege levels of memory accesses define a set of *translation regimes*, where a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. See [The VMSAv8-32 translation regimes on page G4-4560](#).

System registers control VMSAv8-32, including defining the location of the translation tables, and enabling and configuring the MMU, including enabling and disabling the different address translation stages. Also, they report any faults that occur on a memory access. For more information, see [Functional grouping of VMSAv8-32 System registers on page G4-4726](#).

The following sections give an overview of VMSAv8-32, and of the implementation options for VMSAv8-32:

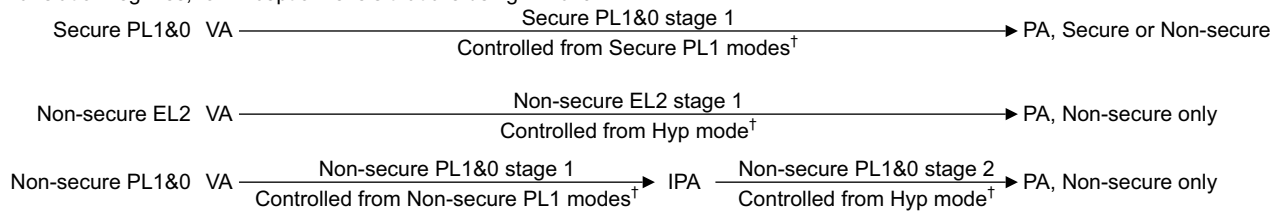

- [The VMSAv8-32 translation regimes.](#)
- [Address types used in a VMSAv8-32 description on page G4-4561.](#)
- [Address spaces in VMSAv8-32 on page G4-4561.](#)
- [About address translation for VMSAv8-32 on page G4-4562.](#)

The remainder of the chapter fully describes the VMSA, including the different implementation options, as summarized in [Organization of the remainder of this chapter on page G4-4565.](#)

### G4.1.1 The VMSAv8-32 translation regimes

As introduced in [Address translation mappings on page G4-4559](#), a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. [Figure G4-1](#) shows the VMSAv8-32 translation regimes, and their associated translation stages and the Exception levels from which they are controlled.

Translation regimes, for Exception levels that are using AArch32

† Typical control when controlled from an Exception level using AArch32.

**Figure G4-1 VMSAv8-32 translation regimes, and associated control**

#### ———— Note ————

Conceptually, a translation regime that has only a stage 1 address translation is equivalent to a regime with a fixed, flat stage 2 mapping from IPA to PA.

[Limited use of Privilege level in ARMv8 AArch32 state on page G1-4319](#) describes the mapping between the PE modes and the Privilege levels (PLs).

### Alternative descriptions of the PL1&0 translation regime

The PL1&0 is described in terms of Privilege level because of the way the AArch32 PE modes map onto the Exception levels, as described in [Limited use of Privilege level in ARMv8 AArch32 state on page G1-4319](#). The description of this translation regime in terms of the Exception levels using depends on the current state of the PE, as follows:

- In Non-secure state, PL1 always maps to EL1, and therefore the Non-secure PL1&0 translation regime could be described as the Non-secure EL1&0 translation regime.
- In Secure state:
  - When EL3 is using AArch32, PL1 maps to EL3, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL3&0 translation regime,
  - When EL3 is using AArch64, Secure PL1 maps to Secure EL1, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL1&0 translation regime,

However, these descriptions all refer to the same translation regime, with the same System registers that are associated with its stage 1 translations. Therefore, the regime is generally referred to as the PL1&0 translation regime.

#### ———— Note ————

As [Figure G4-1](#) shows, Stage 2 translation is supported only in Non-secure state.

## G4.1.2 Address types used in a VMSAv8-32 description

A description of VMSAv8-32 refers to the following address types.

### ———— Note ————

These descriptions relate to a VMSAv8-32 description and therefore sometimes differ from the generic definitions given in the Glossary.

#### Virtual address (VA)

An address that is used in an instruction, as a data or instruction address, is a virtual address (VA).

An address that is held in the PC, LR, or SP, is a VA.

The VA map runs from zero to the size of the VA space. For AArch32 state, the maximum VA space is 4GB, giving a maximum VA range of 0x00000000-0xFFFFFFFF.

#### Intermediate physical address (IPA)

In a translation regime that provides two stages of address translation, the IPA is the address after the stage 1 translation, and is the input address for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA.

A VMSAv8-32 implementation provides only one stage of address translation:

- If the implementation does not include EL2.
- When executing in Secure state.
- When executing in Hyp mode.

#### Physical address (PA)

The address of a location in the Secure or Non-secure memory map. That is, an output address from the PE to the memory system.

## G4.1.3 Address spaces in VMSAv8-32

For execution in AArch32 state, the ARMv8 architecture supports:

- A VA space of up to 32 bits. The actual width is IMPLEMENTATION DEFINED.
- An IPA space of up to 40 bits. The translation tables and associated System registers define the width of the implemented address space.

### ———— Note ————

AArch32 defines two translation table formats. The *Long-descriptor* format gives access to the full 40-bit IPA or PA space at a granularity of 4KB. The *Short-descriptor* format:

- Gives access to a 32-bit PA space at 4KB granularity.
- Gives access to a 40-bit PA space, but only at 16MB granularity, by the use of Supersections.

If an implementation includes EL3, the address maps are defined independently for Secure and Non-secure operation, providing two independent 40-bit address spaces, where:

- A VA accessed from Non-secure state can only be translated to the Non-secure address map.
- A VA accessed from Secure state can be translated to either the Secure or the Non-secure address map.

## G4.1.4 About address translation for VMSAv8-32

Address translation is the process of mapping one address type to another, for example, mapping VAs to IPAs, or mapping VAs to PAs. A *translation table* defines the mapping from one address type to another, and a *Translation table base register (TTBR)* indicates the start of a translation table. Each implemented stage of address translation shown in [Figure G4-1 on page G4-4560](#) requires its own translation tables.

For PL1&0 stage 1 translations, the mapping can be split between two tables, one controlling the lower part of the VA space, and the other controlling the upper part of the VA space. This can be used, for example, so that:

- One table defines the mapping for operating system and I/O addresses, that do not change on a context switch.
- A second table defines the mapping for application-specific addresses, and therefore might require updating on a context switch.

The VMSAv8-32 implementation options determine the supported address translation stages. The following descriptions apply when all implemented Exception levels are using AArch32:

### VMSAv8-32 without EL2 or EL3

Supports only a single PL1&0 stage 1 address translation. Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by [TTBR0](#) and [TTBR1](#), and controlled by [TTBCR](#).

### VMSAv8-32 with EL3 but without EL2

Supports only the Secure PL1&0 stage 1 address translation and the Non-secure PL1&0 stage 1 address translation. In each Security state, this stage of translation can be split between two sets of translation tables, with base addresses defined by the Secure and Non-secure copies of [TTBR0](#) and [TTBR1](#), and controlled by the Secure and Non-secure copies of [TTBCR](#).

### VMSAv8-32 with EL2 but without EL3

The implementation supports the following stages of address translation:

#### Non-secure PL2 stage 1 address translation

The [HTTBR](#) defines the base address of the translation table for this stage of address translation, controlled by [HTCR](#).

#### Non-secure PL1&0 stage 1 address translation

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of [TTBR0](#) and [TTBR1](#) and controlled by the Non-secure instance of [TTBCR](#).

#### Non-secure PL1&0 stage 2 address translation

The [VTTBR](#) defines the base address of the translation table for this stage of address translation, controlled by [VTCR](#).

### VMSAv8-32 with EL2 and EL3

The implementation supports all the stages of address translation, as follows:

#### Secure PL1&0 stage 1 address translation

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Secure copies of [TTBR0](#) and [TTBR1](#), and controlled by the Secure instance of [TTBCR](#).

#### Non-secure PL2 stage 1 address translation

The [HTTBR](#) defines the base address of the translation table for this stage of address translation, controlled by [HTCR](#).

#### Non-secure PL1&0 stage 1 address translation

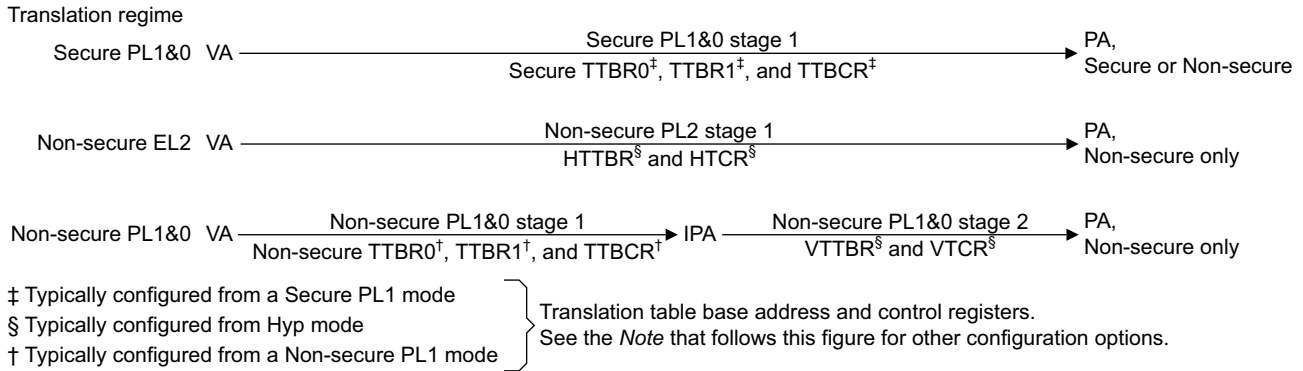

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of [TTBR0](#) and [TTBR1](#) and controlled by the Non-secure instance of [TTBCR](#).

### Non-secure PL1&0 stage 2 address translation

The **VTTBR** defines the base address of the translation table for this stage of address translation, controlled by **VTCCR**.

Figure G4-2 shows the translation regimes and stages in a VMSAv8-32 implementation that includes all the Exception levels, and indicates the PE mode that, typically, defines each set of translation tables, if that stage of address translation is controlled by a Privilege level that is using AArch32:

**Figure G4-2 VMSAv8-32 address translation summary**

#### Note

The term *Typically configured* is used in Figure G4-2 to indicate the expected software usage. However, stages of address translation used in AArch32 state can also be configured:

- From an Exception level higher than the Exception level of the configuring PE mode shown in Figure G4-2, regardless of whether that Exception level is using AArch32 or is using AArch64, except that a Non-secure Exception level can never configure a stage of address translation that is used in Secure state.
- From an Exception level that is using AArch64 and is higher than the level at which the translation stage is being used. For example, if Non-secure EL0 is the only Non-secure Exception level that is using AArch32, then the Non-secure PL1&0 stage of address translation is configured from Non-secure EL1, that is using AArch64.

In general:

- The translation from VA to PA can require multiple *stages* of address translation, as Figure G4-2 shows.
- A single stage of address translation takes an *input address* and translates it to an *output address*.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single input address to output address translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The required output address.
- The *attributes* and *access permissions* of the addressed memory.

*Translation Lookaside Buffers* (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and VMSAv8-32 provides TLB maintenance instructions for the management of TLB contents.

#### Note

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

To reduce the software overhead of TLB maintenance, for the PL1&0 translation regimes VMSAv8-32 distinguishes between *Global pages* and *Process-specific pages*. The *Address Space Identifier* (ASID) identifies pages that are associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

If an implementation includes EL2, the *virtual machine identifier* (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs. For stage 2 translations, all translations are associated with the current VMID. There is no mechanism to associate a particular stage 2 translation with multiple virtual machines.

### Atomicity of register changes on changing virtual machine

From the viewpoint of software executing at Non-secure PL1 or PL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This rule applies to the registers for the Non-secure PL1&0 translation regime. This means that all of the following registers must change atomically:

- The registers that are associated with the stage 1 translations:
  - [MAIR0](#), [MAIR1](#), [AMAIR0](#), and [AMAIR1](#).
  - [TTBR0](#), [TTBR1](#), [TTBCR](#), [TTBCR2](#), and [CONTEXTIDR](#).
  - [SCTLR](#).
- The registers that are associated with the stage 2 translations:
  - [VTTBR](#) and [VTCR](#).
  - [HSCTLR](#).

#### ———— Note ————

Only some fields of [SCTLR](#) affect the stage 1 translation, and only some fields of [HSCTLR](#) affect the stage 2 translation. However, in each case, changing these fields requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the Non-secure PL1&0 translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are out of context when they are updated, and no synchronization precautions are required.

### Use of out-of-context translation regimes

The architecture requires that:

- When executing at EL3 or EL2, the PE must not use the registers that are associated with the Non-secure PL1&0 translation regime for speculative memory accesses.
- When executing at EL3 the PE must not use the registers that are associated with the EL2 translation regime for speculative memory accesses.
- When executing at EL3, EL2, or Non-secure EL1, the PE must not use the registers that are associated with the Secure PL1&0 translation regime for speculative memory accesses.

When entering an Exception level on completion of a DSB instruction, no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered, will be observed by any observers to the extent that those accesses are required to be observed, as determined by the Shareability and Cacheability of those translation table entries.

#### ———— Note ————

- This does not require that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.

- This requirement does not imply that, on taking an exception to a higher Exception level, any translation table walks started before the exception was taken will be completed by the time the higher Exception level is entered, and therefore memory accesses required for such a translation table walk might, in effect, be performed speculatively. However, the execution of a DSB on entry to the higher Exception level ensures that these accesses are complete.

## G4.1.5 Organization of the remainder of this chapter

The remainder of this chapter is organized as follows.

The next part of the chapter describes address translation and the associated memory properties held in the translation table entries, in the following sections:

- *The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4567.*
- *Translation tables on page G4-4571.*
- *Secure and Non-secure address spaces on page G4-4574.*
- *The VMSAv8-32 Short-descriptor translation table format on page G4-4576.*
- *The VMSAv8-32 Long-descriptor translation table format on page G4-4585.*
- *Memory access control on page G4-4605.*
- *Memory region attributes on page G4-4616.*
- *Translation Lookaside Buffers (TLBs) on page G4-4628.*
- *TLB maintenance requirements on page G4-4632.*

*Caches in VMSAv8-32 on page G4-4646* describes VMSAv8-32-specific cache requirements.

The following sections then describe aborts on VMSAv8-32 memory accesses, and how these and other faults are reported:

- *VMSAv8-32 memory aborts on page G4-4649.*
- *Exception reporting in a VMSAv8-32 implementation on page G4-4663.*

*Address translation instructions on page G4-4682* then describes these operations, and how they relate to address translation.

A number of sections then describe the System registers for VMSAv8-32. The following sections give general information about the System registers, and the organization of the registers in the primary encoding spaces, (coproc==0b1110) and (coproc==0b1111) for these registers:

- *About the System registers for VMSAv8-32 on page G4-4689.*
- *VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G4-4704.*
- *VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G4-4707.*
- *Functional grouping of VMSAv8-32 System registers on page G4-4726.*

The following sections then describe each of the functional groups of the System registers in the (coproc==0b1111) encoding space, including a full description of each register in the group:

- *Identification registers, functional group on page G4-4727.*
- *Virtual memory control registers, functional group on page G4-4729.*
- *Exception and fault handling registers, functional group on page G4-4733.*
- *General system control registers, functional group on page G4-4728.*
- *Lockdown, DMA, and TCM features, functional group on page G4-4738.*
- *Cache maintenance instructions, functional group on page G4-4734.*
- *TLB maintenance instructions, functional group on page G4-4735.*
- *Address translation instructions, functional group on page G4-4737.*
- *Legacy feature registers, functional group on page G4-4744.*
- *Performance Monitors Extension registers, functional group on page G4-4738.*
- *Security registers, functional group on page G4-4732.*
- *Virtualization registers, functional group on page G4-4730.*
- *IMPLEMENTATION DEFINED registers, functional group on page G4-4744.*

---

**Note**

---

The System registers in the (coproc==0b1110) encoding space provide the following functionality:

- Self-hosted debug. These registers are described in [Debug registers on page G6-5239](#).
- The System register interface to a trace macrocell. These registers are not described in this manual.
- Jazelle registers. These registers are summarized in [Legacy feature registers, functional group on page G4-4744](#).

Therefore, there is no summary of these registers by functional groups.

---

[Pseudocode description of VMsAv8-32 memory system operations on page G4-4748](#) then summarizes the pseudocode functions that describe many features of VMsAv8-32 operation.

## G4.2 The effects of disabling address translation stages on VMSAv8-32 behavior

*About VMSAv8-32 on page G4-4558* defines the translation regimes and the associated stages of address translation, each of which has its own System registers for control and configuration. VMSAv8-32 includes an enable bit for each stage of address translation, as follows:

- [SCTLR.M](#), in the Secure instance of the register, controls Secure PL1&0 stage 1 address translation.
- [SCTLR.M](#), in the Non-secure instance of the register, controls Non-secure PL1&0 stage 1 address translation.
- [HCR.VM](#) controls Non-secure PL1&0 stage 2 address translation.
- [HSCTLR.M](#) controls Non-secure PL2 stage 1 address translation.

### ———— Note ————

- The descriptions throughout this chapter describe address translation as seen by Exception levels that are using AArch32. However, for the Non-secure PL1&0 translation regime, the stage 2 translation:
  - Is controlled by the [HCR](#) if EL2 is using AArch32.
  - Is controlled by the [HCR\\_EL2](#) if EL2 is using AArch64.

For this reason, links to the [HCR](#) link to a table that disambiguates between the AArch32 [HCR](#) and the AArch64 [HCR\\_EL2](#).
- If EL2 is using AArch64, then the equivalent of the Non-secure PL2 translation regime is described in [Chapter D4 The AArch64 Virtual Memory System Architecture](#), not in this chapter.

The following sections describe the effect on VMSAv8-32 behavior of disabling each stage of translation:

- [VMSAv8-32 behavior when stage 1 address translation is disabled](#).
- [VMSAv8-32 behavior when stage 2 address translation is disabled on page G4-4569](#).
- [Behavior of instruction fetches when all associated address translations are disabled on page G4-4569](#).

[Enabling stages of address translation on page G4-4569](#) gives more information about each stage of address translation, in particular after a reset on an implementation that includes EL3.

### G4.2.1 VMSAv8-32 behavior when stage 1 address translation is disabled

When stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of address translation are treated as follows:

#### Non-secure PL1 and PL0 accesses when EL2 is implemented and [HCR.DC](#) is set to 1

In an implementation that includes EL2, for an access from a Non-secure PL1 or PL0 mode when [HCR.DC](#) is set to 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes. See also [Effect of the HCR.DC field on page G4-4568](#).

#### All other accesses

For all other accesses, when a stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

##### Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

##### Instruction access

The stage 1 translation assigns Normal memory attribute, with the Cacheability and Shareability attributes determined by the value of:

- The Secure instance of [SCTLR.I](#) for the Secure PL1&0 translation regime.
- The Non-secure instance of [SCTLR.I](#) for the Non-secure PL1&0 translation regime.
- [HSCTLR.I](#) for the Non-secure PL2 translation regime.

In these cases, the meaning of the I field is as follows:

**When I is set to 0**

The stage 1 translation assigns the attributes Outer Shareable, Non-cacheable.

**When I is set to 1**

The stage 1 translation assigns the attributes Inner Write-Through Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

---

**Note**

On some implementations, if the [SCTLR.TRE](#) field is set to 0 then this behavior can be changed by the remap settings in the memory remap registers. The details of TEX remap when [SCTLR.TRE](#) is set to 0 are IMPLEMENTATION DEFINED, see [SCTLR.TRE](#), [SCTLR.M](#), and the effect of the TEX remap registers on page G4-4621.

---

For this stage of translation, no memory access permission checks are performed, and therefore no MMU faults relating to this stage of translation can be generated.

---

**Note**

Alignment checking is performed, and therefore Alignment faults can occur.

---

For every access, when stage 1 translation is disabled, the output address of the stage 1 translation is equal to the input address. This is called a flat address mapping. If the implementation supports output addresses of more than 32 bits then the output address bits above bit[31] are zero. For example, for a VA to PA translation on an implementation that supports 40-bit PAs, PA[39:32] is 0x00.

For a Non-secure PL1 or PL0 access, if the PL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

See also [Behavior of instruction fetches when all associated address translations are disabled](#) on page G4-4569.

## Effect of the HCR.DC field

The [HCR.DC](#) field determines the default memory attributes assigned for the first stage of the Non-secure PL1&0 translation regime when that stage of translation is disabled.

When executing in a Non-secure PL1 or PL0 mode with [HCR.DC](#) set to 1:

- For all purposes other than reading the value of the [SCTLR](#), the PE behaves as if the value of the [SCTLR.M](#) field is 0. This means Non-secure PL1&0 stage 1 address translation is disabled.
- For all purposes other than reading the value of the [HCR](#), the PE behaves as if the value of the [HCR.VM](#) field is 1. This means Non-secure PL1&0 stage 2 address translation is enabled.

The effect of [HCR.DC](#) might be held in TLB entries associated with a particular VMID. Therefore, if software executing at EL2 changes the [HCR.DC](#) value without also changing the current VMID, it must also invalidate all TLB entries associated with the current VMID. Otherwise, the behavior of Non-secure software executing at EL1 or EL0 is CONstrained UNPREDICTABLE, see [CONstrained UNPREDICTABLE behaviors due to caching of control or data values](#) on page K1-6101.

## Effect of disabling translation on maintenance and address translation instructions

Cache maintenance instructions act on the target cache whether address translation is enabled or not, and regardless of the values of the memory attributes. However, if a stage of translation is disabled, they use the flat address mapping for that stage, and all mappings are considered global.

TLB invalidate operations act on the target TLB whether address translation is enabled or not.

When the Non-secure PL1&0 stage 1 address translation is disabled, any [ATS1C\\*\\*](#) or [ATS12NSO\\*\\*](#) address translation instruction that accesses the Non-secure state translation reflects the effect of the [HCR.DC](#) field.

## G4.2.2 VMSAv8-32 behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

- The IPA output from the stage 1 translation maps flat to the PA
- The memory attributes and permissions from the stage 1 translation apply to the PA.

If the stage 1 address translation and the stage 2 address translation are both disabled, see [Behavior of instruction fetches when all associated address translations are disabled](#).

## G4.2.3 Behavior of instruction fetches when all associated address translations are disabled

The information in this section applies to memory accesses:

- From Secure PL1 and PL0 modes, when the Secure PL1&0 stage 1 address translation is disabled
- From Hyp mode, when the Non-secure PL2 stage 1 address translation is disabled
- From Non-secure PL1 and PL0 modes, when all of the following apply:
  - The Non-secure PL1&0 stage 1 address translation is disabled.
  - The Non-secure PL1&0 stage 2 address translation is disabled.
  - [HCR.DC](#) is set to 0.

In these cases, when execution is in AArch32 state a memory location might be accessed as a result of an instruction fetch if either:

- The memory location is in the same 4KB block of memory, aligned to 4KB, as an instruction which a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset, or is in the 4KB block immediately following such a block.
- The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
  - The last reset.
  - If the branch predictor is architecturally invisible, the last synchronization of instruction cache maintenance targeting the address of the branch instruction.
  - If the branch predictor is not architecturally invisible, the last synchronization of branch predictor maintenance targeting the address of the branch instruction.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

### ———— Note ————

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when address translation is disabled are located in 4KB blocks of the address space that contain only memory that is tolerant to speculative accesses.
- Each 4KB block of the address space that immediately follows a 4KB block that holds instructions that will be executed when address translation is disabled also contains only memory that is tolerant to speculative accesses.

## G4.2.4 Enabling stages of address translation

On powerup or reset, only the [SCTLR.M](#) field for the Exception level and Security state entered on reset is reset to 0, disabling address translation for the initial state of the PE. All other [SCTLR.M](#) and [HSCTLR.M](#) fields that are implemented are UNKNOWN after the reset.

This means, on powerup or reset:

- On an implementation that includes EL3, where EL3 is using AArch32:
  - The PL1&0 stage 1 address translation enable bit, [SCTLR.M](#), is Banked, meaning there are separate enables for operation in Secure and Non-secure state.
  - If EL3 is using AArch32, only the Secure instance of the [SCTLR.M](#) field resets to 0, disabling the Secure state PL1&0 stage 1 address translation. The reset value of the Non-secure instance of [SCTLR.M](#) is UNKNOWN.
- On an implementation that includes EL2, where EL2 is using AArch32, the [HSCTLR.M](#) field, that controls the Non-secure PL2 stage 1 address translation:
  - If the implementation does not include EL3, resets to 0.
  - Otherwise, is UNKNOWN.
- On an implementation that does not include either EL2 or EL3, there is a single stage of translation. This is controlled by [SCTLR.M](#), that resets to 0.

———— **Note** ————

If, for the software that enables or disables a stage of address translation, the input address of a stage 1 translation differs from the output address of that stage 1 translation, and the software is running in translation regime that is affected by that stage of translation, then the requirement to synchronize changes to the System registers means it is uncertain where in the instruction stream the change of the translation takes place. For this reason, ARM strongly recommends that the input address and the output address are identical in this situation.

## G4.3 Translation tables

VMSAv8-32 defines two alternative translation table formats:

### Short-descriptor format

It uses 32-bit descriptor entries in the translation tables, and provides:

- Up to two levels of address lookup.
- 32-bit input addresses.
- Output addresses of up to 40 bits.
- Support for PAs of more than 32 bits by use of supersections, with 16MB granularity.
- Support for No access, Client, and Manager domains.

### Long-descriptor format

It uses 64-bit descriptor entries in the translation tables, and provides:

- Up to three levels of address lookup.
- Input addresses of up to 40 bits, when used for stage 2 translations.
- Output addresses of up to 40 bits.
- 4KB assignment granularity across the entire PA range.
- No support for domains, all memory regions are treated as in a Client domain.
- Fixed 4KB table size, unless truncated by the size of the input address space.

#### ————— Note —————

- Translation with a 40-bit input address range requires two concatenated 4KB top-level tables, aligned to 8KB.
- The VMSAv8-64 Long-descriptor translation table format is generally similar to this format, but supports input and output addresses of up to 48 bits, and has an assignment granularity and table size defined by its *translation granule*. This can be 4KB, 16KB, or 64KB. See [The VMSAv8-64 translation table format on page D4-2042](#).

In all implementations, of the possible address translations shown in [Figure G4-2 on page G4-4563](#), for stages of address translation that are using AArch32:

- In a particular Security state, the translation tables for the PL1&0 stage 1 translations can use either translation table format, and the [TTBCR.EAE](#) field indicates the current translation table format.
- The translation tables for the Non-secure PL2 stage 1 translations, and for the Non-secure PL1&0 stage 2 translations, must use the Long-descriptor translation table format.

Many aspects of performing a translation table walk depend on the current translation table format. Therefore, the following sections describe the two formats, including how the MMU performs a translation table walk for each format:

- [The VMSAv8-32 Short-descriptor translation table format on page G4-4576](#).
- [The VMSAv8-32 Long-descriptor translation table format on page G4-4585](#).

The following subsections describe aspects of the translation tables and translation table walks, for memory accesses from AArch32 state, that are independent of the translation table format:

- [Translation table walks for memory accesses using VMSAv8-32 translation regimes on page G4-4572](#).
- [Information returned by a translation table lookup on page G4-4572](#).
- [Determining the translation table base address in the VMSAv8-32 translation regimes on page G4-4573](#).
- [Control of translation table walks on a TLB miss on page G4-4574](#).
- [Access to the Secure or Non-secure physical address map on page G4-4574](#).

See also [TLB maintenance requirements on page G4-4632](#).

### G4.3.1 Translation table walks for memory accesses using VMSAv8-32 translation regimes

A translation table walk occurs as the result of a TLB miss, and starts with a read of the appropriate starting-level translation table. The result of that read determines whether additional translation table reads are required, for this stage of translation, as described in either:

- [Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G4-4582.](#)
- [Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G4-4600.](#)

---

#### Note

When using the Short-descriptor translation table format, the starting level for a translation table walk is always a level 1 lookup. However, with the Long-descriptor translation table format, the starting-level can be either a level 1 or a level 2 lookup.

---

For the PL1&0 stage 1 translations, [SCTLR.EE](#) determines the endianness of the translation table lookups. [SCTLR](#) is Banked, and therefore the endianness is determined independently for each Security state.

[HSCTLR.EE](#) defines the endianness for the Non-secure PL2 stage 1 and Non-secure PL1&0 stage 2 translations.

---

#### Note

##### Dynamically changing translation table endianness

Because any change to [SCTLR.EE](#) or [HSCTLR.EE](#) requires synchronization before it is visible to subsequent operations, ARM strongly recommends that:

- [SCTLR.EE](#) is changed only when either:
  - Executing in a mode that does not use the translation tables affected by [SCTLR.EE](#).
  - Executing with [SCTLR.M](#) set to 0.
- [HSCTLR.EE](#) is changed only when either:
  - Executing in a mode that does not use the translation tables affected by [HSCTLR.EE](#).
  - Executing with [HSCTLR.M](#) set to 0.

---

The physical address of the base of the starting-level translation table is determined from the appropriate [TTBR](#), see [Determining the translation table base address in the VMSAv8-32 translation regimes on page G4-4573.](#)

For more information, see [Ordering and completion of TLB maintenance instructions on page G4-4635.](#)

Translation table walks must access data or unified caches, or data and unified caches, of other agents participating in the coherency protocol, according to the Shareability attributes described in the TTBR. These Shareability attributes must be consistent with the Shareability attributes for the translation tables themselves.

### G4.3.2 Information returned by a translation table lookup

When an associated stage of address translation is enabled, a memory access requires one or more translation table lookups. If the required translation table descriptor is not held in a TLB, a translation table walk is performed to obtain the descriptor. A lookup, whether from the TLB or as the result of a translation table walk, returns both:

- An output address that corresponds to the input address for the lookup.
- A set of properties that correspond to that output address.

The returned properties are classified as providing *address map control*, *access controls*, or *region attributes*. This classification determines how the descriptions of the properties are grouped. The classification is based on the following model:

#### Address map control

Memory accesses from Secure state can access either the Secure or the Non-secure address map, as summarized in [Access to the Secure or Non-secure physical address map on page G4-4574.](#)

Memory accesses from Non-secure state can only access the Non-secure address map.

### Access controls

Determine whether the PE, in its current state, can access the output address that corresponds to the given input address. If not, an MMU fault is generated and there is no memory access.

*Memory access control on page G4-4605 describes the properties in this group.*

### Attributes

Are valid only for an output address that the PE, in its current state, can access. The attributes define aspects of the required behavior of accesses to the target memory region.

*Memory region attributes on page G4-4616 describes the properties in this group.*

## G4.3.3 Determining the translation table base address in the VMSAv8-32 translation regimes

On a TLB miss, the VMSA must perform a translation table walk, and therefore must find the base address of the translation table to use for its lookup. A TTBR holds this address. As [Figure G4-2 on page G4-4563](#) shows:

- For a Non-secure PL2 stage 1 translation, the [HTTBR](#) holds the required base address. The [HTCR](#) is the control register for these translations.
- For a Non-secure PL1&0 stage 2 translation, the [VTTBR](#) holds the required base address. The [VTCT](#) is the control register for these translations.
- For a PL1&0 stage 1 translation, either [TTBR0](#) or [TTBR1](#) holds the required base address. The [TTBCR](#) is the control register for these translations.

The Non-secure copies of [TTBR0](#), [TTBR1](#), and [TTBCR](#), relate to the Non-secure PL1&0 stage 1 translation. The Secure copies of [TTBR0](#), [TTBR1](#), and [TTBCR](#), relate to the Secure PL1&0 stage 1 translation.

For the PL1&0 translation table walks:

- [TTBR0](#) can be configured to describe the translation of VAs in the entire address map, or to describe only the translation of VAs in the lower part of the address map.
- If [TTBR0](#) is configured to describe the translation of VAs in the lower part of the address map, [TTBR1](#) is configured to describe the translation of VAs in the upper part of the address map.

The contents of the appropriate instance of the [TTBCR](#) determine whether the address map is separated into two parts, and where the separation occurs. The details of the separation depend on the current translation table format, see:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G4-4581.*
- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4594.*

[Example G4-1](#) shows a typical use of the two sets of translation tables:

### Example G4-1 Example use of TTBR0 and TTBR1

An example of using the two TTBRs for PL1&0 stage 1 address translations is:

#### TTBR0

Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- [TTBR0](#) is updated to point to the level 1 translation table for the new context.
- [TTBCR](#) is updated if this change changes the size of the translation table.
- The [CONTEXTIDR](#) is updated.

[TTBCR](#) can be programmed so that all translations use [TTBR0](#) in a manner compatible with architecture versions before ARMv6.

#### TTBR1

Used for operating system and I/O addresses, that do not change on a context switch.

#### G4.3.4 Control of translation table walks on a TLB miss

Two fields in the [TCR](#) for the translation stage required by a memory access control whether a translation table walk is performed on a TLB miss. These two fields are the:

- PD0 and PD1 fields, on a PE using the Short-descriptor translation table format.
- EPD0 and EPD1 fields, on a PE using the Long-descriptor translation table format.

---

**Note**

For the VMSAv8-32 translation regimes, the different field names are because the fields are in different positions in [TTBCR](#), depending on the translation table format.

---

The effect of these fields is:

**{E}PDx == 0** If a TLB miss occurs based on TTBRx, a translation table walk is performed. The current Security state determines whether the memory access is Secure or Non-secure.

**{E}PDx == 1** If a TLB miss occurs based on TTBRx, a level 1 Translation fault is returned, and no translation table walk is performed.

#### G4.3.5 Access to the Secure or Non-secure physical address map

As stated in [Address spaces in VMSAv8-32 on page G4-4561](#), a PE can access independent Secure and Non-secure address maps. When the PL1 Exception level is using AArch32, these are defined by the translation tables identified by the Secure [TTBR0](#) and [TTBR1](#). In both translation table formats in the Secure translation tables, the NS field in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map:

**NS == 0** Access the Secure physical address space.

**NS == 1** Access the Non-secure physical address space.

---

**Note**

In the Non-secure translation tables, the corresponding field is SBZ. Non-secure accesses always access the Non-secure physical address space, regardless of the value of this field.

---

The Long-descriptor translation table format extends this control, adding an NSTable field to the Secure translation tables, as described in [Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G4-4593](#). In the Non-secure translation tables, the corresponding field is SBZ, and Non-secure accesses ignore the value of this field.

The following sections describe the address map controls in the two implementations:

- [Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G4-4581](#).
- [Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4593](#).

The following subsection gives more information.

#### Secure and Non-secure address spaces

EL3 provides two physical address spaces, a Secure physical address space and a Non-secure physical address space.

As described in [Access to the Secure or Non-secure physical address map](#), for the PL1&0 stage 1 translations when controlled from an Exception level using AArch32, the registers that control the stage of translation, [TTBR0](#), [TTBR1](#), [TTBCR](#), and [TTBCR2](#) are Banked to provide independent Secure and Non-secure instances of the registers, and the Security state of the PE when it performs a memory access whether the Secure or Non-secure instances are used. This means that for stage 1 of the PL1&0 translation regime there are independent Secure and Non-secure translation tables, and translation table walks are made to the physical address space corresponding to the Security state of the translation tables used.

For a translation table walk caused by a memory access from Non-secure state, all memory accesses are to the Non-secure address space.

For a translation table walk caused by a memory access from Secure state:

- When address translation is using the Long-descriptor translation table format:
  - The initial lookup performed must access the Secure address space.
  - If a table descriptor read from the Secure address space has the NSTable field set to 0, then the next level of lookup is from the Secure address space.
  - If a table descriptor read from the Secure address space has the NSTable field set to 1, then the next level of lookup, and any subsequent level of lookup, is from the Non-secure address space.

For more information, see [Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4593](#).

- Otherwise, all memory accesses are to the Secure address space.

---

**Note**

- When executing in Non-secure state, additional translations are supported. For memory accesses from AArch32 state these are:
  - Non-secure PL2 stage 1 translation.
  - Non-secure PL1&0 stage 2 translation.

These translations can access only the Non-secure address space.

- A system implementation can alias parts of the Secure physical address space to the Non-secure physical address space in an implementation-specific way. As with any other aliasing of physical memory, the use of aliases in this way can require the use of cache maintenance instructions to ensure that changes to memory made using one alias of the physical memory are visible to accesses to the other alias of the physical memory.
-

## G4.4 The VMSAv8-32 Short-descriptor translation table format

The Short-descriptor translation table format supports a memory map based on memory sections or pages:

**Supersections** Consist of 16MB blocks of memory. Support for Supersections is optional, except that an implementation that supports more than 32 bits of physical address must also support Supersections to provide access to the entire physical address space.

**Sections** Consist of 1MB blocks of memory.

**Large pages** Consist of 64KB blocks of memory.

**Small pages** Consist of 4KB blocks of memory.

Supersections, Sections and Large pages map large regions of memory using only a single TLB entry.

### ———— Note ————

Whether a VMSAv8-32 implementation of the Short-descriptor format translation tables supports supersections is IMPLEMENTATION DEFINED.

When using the Short-descriptor translation table format, two levels of translation tables are held in memory:

#### Level 1 table

Holds *level 1 descriptors* that contain the base address and

- Translation properties for a Section and Supersection.
- Translation properties and pointers to a level 2 table for a Large page or a Small page.

#### Level 2 tables

Hold *level 2 descriptors* that contain the base address and translation properties for a Small page or a Large page. With the Short-descriptor format, level 2 tables can be referred to as *Page tables*.

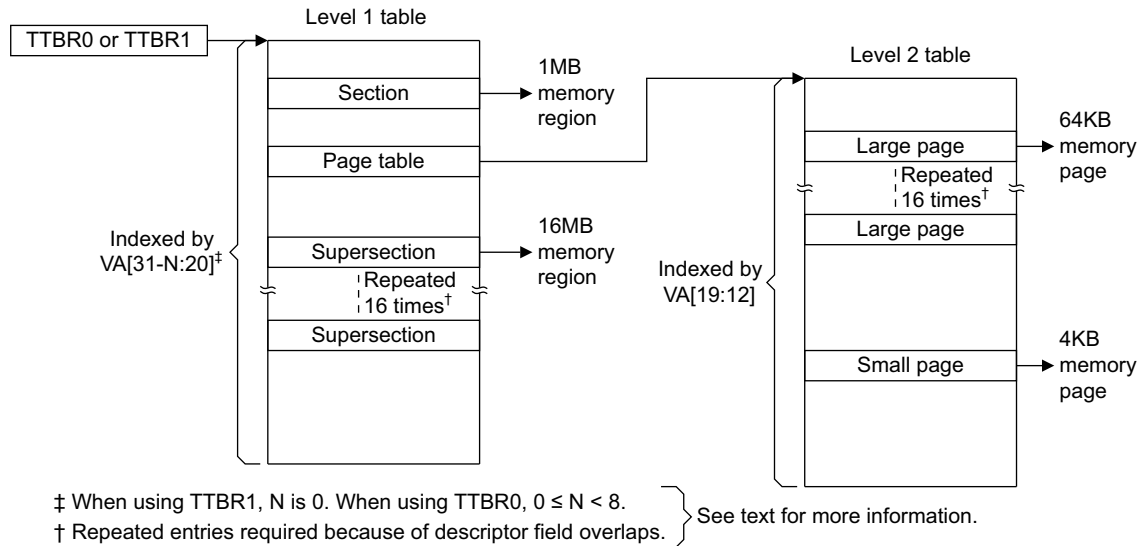

A level 2 table requires 1KB of memory.

In the translation tables, in general, a descriptor is one of:

- An invalid or fault entry.
- A Page table entry, that points to a next-level translation table.
- A page or section entry, that defines the memory properties for the access.
- A reserved format.

Bits[1:0] of the descriptor give the primary indication of the descriptor type.

[Figure G4-3 on page G4-4577](#) gives a general view of address translation when using the Short-descriptor translation table format.

**Figure G4-3 General view of address translation using VMSAv8-32 Short-descriptor format translation tables**

*Additional requirements for Short-descriptor format translation tables on page G4-4580* describes why, when using the Short-descriptor format, Supersection and Large page entries must be repeated 16 times, as shown in *Figure G4-3*.

*VMSAv8-32 Short-descriptor translation table format descriptors, Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4580, and Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G4-4581* describe the format of the descriptors in the Short-descriptor format translation tables.

The following sections then describe the use of this translation table format:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G4-4581.*
- *Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G4-4582.*

#### G4.4.1 VMSAv8-32 Short-descriptor translation table format descriptors

The following sections describe the formats of the entries in the Short-descriptor translation tables:

- *Short-descriptor translation table level 1 descriptor formats on page G4-4578.*
- *Short-descriptor translation table level 2 descriptor formats on page G4-4579.*

For more information about level 2 translation tables see *Additional requirements for Short-descriptor format translation tables on page G4-4580*.

#### ————— Note —————

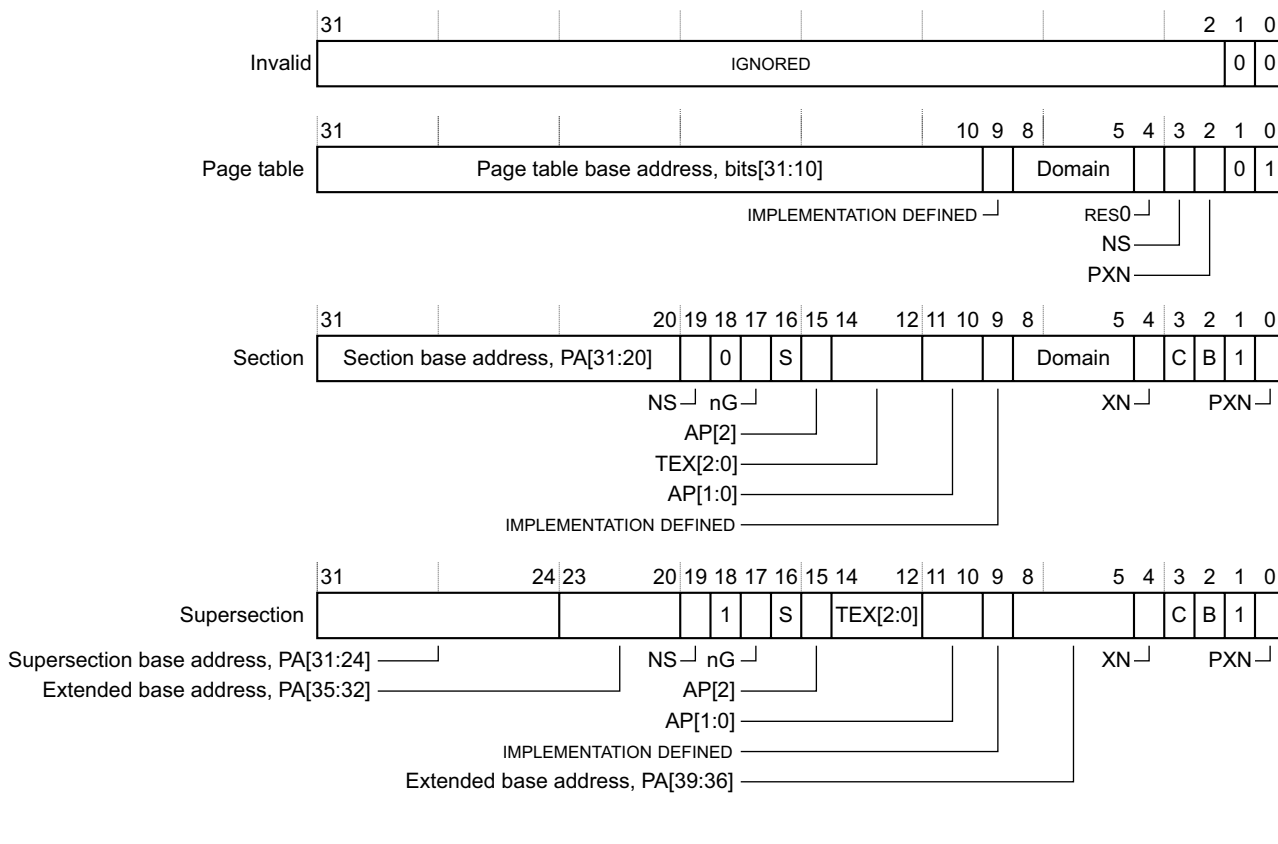

Previous versions of the *ARM Architecture Reference Manual*, and some other documentation, describes the AP[2] bit in the translation table entries as the APX bit.

*Information returned by a translation table lookup on page G4-4572* describes the classification of the non-address fields in the descriptors as address map control, access control, or attribute fields.

## Short-descriptor translation table level 1 descriptor formats

Each entry in the level 1 table describes the mapping of the associated 1MB VA range.

Figure G4-4 shows the possible level 1 descriptor formats.

**Figure G4-4 VMSAv8-32 Short-descriptor level 1 descriptor formats**

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

### 0b00, Invalid entry

The associated VA is unmapped, and any attempt to access it generates a Translation fault.

Bits[31:2] of the descriptor are IGNORED, see *IGNORED* on page Glossary-6341. This means software can use these bits for its own purposes.

### 0b01, Page table

The descriptor gives the address of a level 2 translation table, that specifies the mapping of the associated 1MByte VA range.

### 0b10, Section or Supersection

The descriptor gives the base address of the Section or Supersection. Bit[18] determines whether the entry describes a Section or a Supersection.

This encoding also defines the PXN field as 0.

### 0b11, Section or Supersection, if the implementation supports the PXN attribute

This encoding is identical to 0b10, except that it defines the PXN field as 1.

### Note

A VMSAv8-32 implementation can use the Short-descriptor translation table format for the PL1&0 stage 1 translations, by setting [TTBCR.EAE](#) to 0.

The address information in the level 1 descriptors is:

- Page table** Bits[31:10] of the descriptor are bits[31:10] of the address of a Page table.
- Section** Bits[31:20] of the descriptor are bits[31:20] of the address of the Section.
- Supersection** Bits[31:24] of the descriptor are bits[31:24] of the address of the Supersection.  
Optionally, bits[8:5, 23:20] of the descriptor are bits[39:32] of the extended Supersection address.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see [Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors](#) on page G4-4580.

## Short-descriptor translation table level 2 descriptor formats

Figure G4-5 shows the possible formats of a level 2 descriptor.

**Figure G4-5 Short-descriptor level 2 descriptor formats**

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

#### 0b00, Invalid entry

The associated VA is unmapped, and attempting to access it generates a Translation fault.

Bits[31:2] of the descriptor are *IGNORED*, see [IGNORED](#) on page Glossary-6341. This means software can use these bits for its own purposes.

#### 0b01, Large page

The descriptor gives the base address and properties of the Large page.

#### 0b1x, Small page

The descriptor gives the base address and properties of the Small page.

In this descriptor format, bit[0] of the descriptor is the XN field.

The address information in the level 2 descriptors is:

- Large page** Bits[31:16] of the descriptor are bits[31:16] of the address of the Large page.
- Small page** Bits[31:12] of the descriptor are bits[31:12] of the address of the Small page.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see [Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors](#).

### Additional requirements for Short-descriptor format translation tables

When using Supersection or Large page descriptors in the Short-descriptor translation table format, the input address field that defines the Supersection or Large page descriptor address overlaps the table address field. In each case, the size of the overlap is 4 bits. The following diagrams show these overlaps:

- [Figure K6-14 on page K6-6194](#) for the level 1 translation table entry for a Supersection.
- [Figure K6-16 on page K6-6196](#) for the level 2 translation table entry for a Large page.

Considering the case of using Large page descriptors in a level 2 translation table, this overlap means that for any specific Large page, the bottom four bits of the level 2 translation table entry might take any value from 0b0000 to 0b1111. Therefore, each of these sixteen index values must point to a separate copy of the same descriptor.

This means that each Large page or Supersection descriptor must:

- Occur first on a sixteen-word boundary.
- Be repeated in 16 consecutive memory locations.

## G4.4.2 Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors

This section describes the descriptor fields other than the descriptor type field and the address field:

### TEX[2:0], C, B

Memory region attribute fields, see [Memory region attributes on page G4-4616](#).

These fields are not present in a descriptor for a Page table.

### XN bit

The Execute-never bit. Determines whether the PE can execute software from the addressed region, see [Access permissions for instruction execution on page G4-4609](#).

This bit is not present in a descriptor for a Page table.

### PXN bit

The Privileged execute-never bit. Determines whether the PE can execute software from the region when executing at PL1, see [Access permissions for instruction execution on page G4-4609](#).

### ————— Note —————

Memory accesses by software executing at EL2 always use the Long-descriptor translation table format.

When this bit is set to 1 in the descriptor for a Page table, it indicates that all memory pages described in the corresponding Page table are Privileged execute-never.

### NS bit

Non-secure bit. Specifies whether the translated PA is in the Secure or Non-secure address map, see [Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G4-4581](#).

This bit is not present in level 2 descriptors. The value of the NS bit in a level 1 descriptor for a Page table applies to all entries in the corresponding level 2 translation table.

### Domain

Domain field, see [Domains, Short-descriptor format only on page G4-4612](#).

This field is not present in a Supersection entry. Memory described by Supersections is in domain 0.

This bit is not present in level 2 descriptors. The value of the Domain field in the level 1 descriptor for a Page table applies to all entries in the corresponding level 2 translation table.

### An IMPLEMENTATION DEFINED bit

This bit is not present in level 2 descriptors.

#### AP[2], AP[1:0]

Access Permissions bits, see [Memory access control](#) on page G4-4605.

AP[0] can be configured as the *Access flag*, see [The Access flag](#) on page G4-4613.

These bits are not present in a descriptor for a Page table.

#### S bit

Shareable bit. Used in determining the Shareability of the addressed region, see [Memory region attributes](#) on page G4-4616.

#### ———— Note ————

The naming of this bit as the *Shareable* bit is carried forward from early versions of the ARM architecture. This name is no longer an adequate description of the interpretation of the bit.

This bit is not present in a descriptor for a Page table.

#### nG bit

The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all **ASID** values, or only to the current **ASID** value. See [Global and process-specific translation table entries](#) on page G4-4628.

This bit is not present in a descriptor for a Page table.

#### Bit[18], when bits[1:0] indicate a *Section or Supersection* descriptor

- |   |                                   |
|---|-----------------------------------|
| 0 | Descriptor is for a Section.      |
| 1 | Descriptor is for a Supersection. |

### G4.4.3 Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format

[Access to the Secure or Non-secure physical address map](#) on page G4-4574 describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Short-descriptor translation table format, the NS bit is defined only in the level 1 translation tables. This means that, in a level 1 descriptor for a Page table, the NS bit defines the physical address map, Secure or Non-secure, for all of the Large pages and Small pages of memory described by that table.

The NS bit of a level 1 descriptor for a Page table has no effect on the physical address map in which that translation table is held. As stated in [Secure and Non-secure address spaces](#) on page G4-4574, the physical address of that translation table is in:

- The Secure address map if the translation table walk is in Secure state.
- The Non-secure address map if the translation table walk is in Non-secure state.

This means the granularity of the Secure and Non-secure memory maps is 1MB. However, in these memory maps, table entries can define physical memory regions with a granularity of 4KB.

### G4.4.4 Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format

As described in [Determining the translation table base address in the VMSAv8-32 translation regimes](#) on page G4-4573, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and **TTBR0** and **TTBR1** hold the base addresses for the two sets of tables. When using the Short-descriptor translation table format, the value of **TTBCR.N** indicates the number of most significant bits of the input VA that determine whether **TTBR0** or **TTBR1** holds the required translation table base address, as follows:

- If N == 0 then use **TTBR0**. Setting **TTBCR.N** to zero disables use of a second set of translation tables.
- If N > 0 then:
  - If bits[31:32-N] of the input VA are all zero then use **TTBR0**.
  - Otherwise use **TTBR1**.

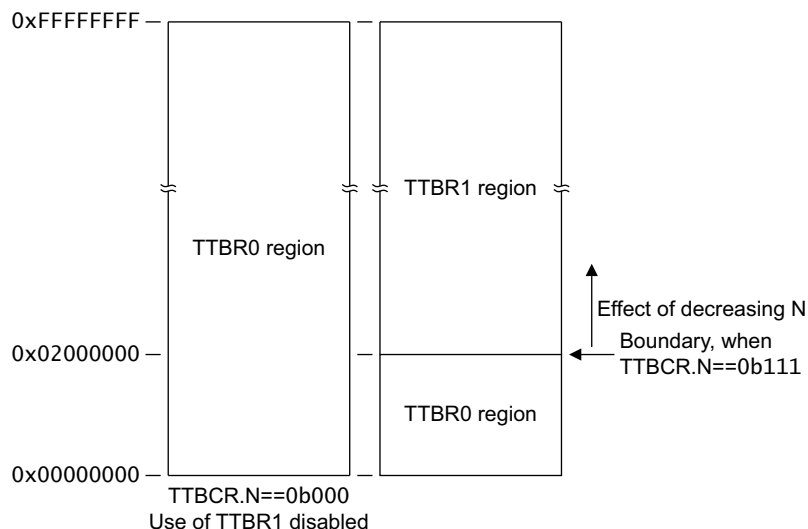

Table G4-1 shows how the value of N determines the lowest address translated using TTBR1, and the size of the level 1 translation table addressed by TTBR0.

**Table G4-1 Effect of TTBCR.N on address translation, Short-descriptor format**

TTBCR.N	First address translated with TTBR1	TTBR0 table	
		Size	Index range
0b000	TTBR1 not used	16KB	VA[31:20]
0b001	0x80000000	8KB	VA[30:20]
0b010	0x40000000	4KB	VA[29:20]
0b011	0x20000000	2KB	VA[28:20]
0b100	0x10000000	1KB	VA[27:20]
0b101	0x08000000	512 bytes	VA[26:20]
0b110	0x04000000	256 bytes	VA[25:20]
0b111	0x02000000	128 bytes	VA[24:20]

Whenever TTBCR.N is nonzero, the size of the translation table addressed by TTBR1 is 16KB.

Figure G4-6 shows how the value of TTBCR.N controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

**Figure G4-6 How TTBCR.N controls the boundary between the TTBRs, Short-descriptor format**

In the selected TTBR, bits RGN, S and IRGN[1:0] define the memory region attributes for the translation table walk.

*Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format* describes the translation.

#### G4.4.5 Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format

When using the Short-descriptor translation table format, and a memory access requires a translation table walk:

- A section-mapped access only requires a read of the level 1 translation table.
- A page-mapped access also requires a read of the level 2 translation table.

*Reading a level 1 translation table* describes how either **TTBR1** or **TTBR0** is used, with the accessed VA, to determine the address of the level 1 descriptor.

*Reading a level 1 translation table* shows the output address as A[39:0]:

- For a Non-secure PL1&0 stage 1 translation, this is the IPA of the required descriptor. A Non-secure PL1&0 stage 2 translation of this address is performed to obtain the PA of the descriptor.
- Otherwise, this address is the PA of the required descriptor.

*The full translation flow for Sections, Supersections, Small pages and Large pages on page G4-4584* then shows the complete translation flow for each valid memory access.

## Reading a level 1 translation table

When performing a fetch based on **TTBR0**:

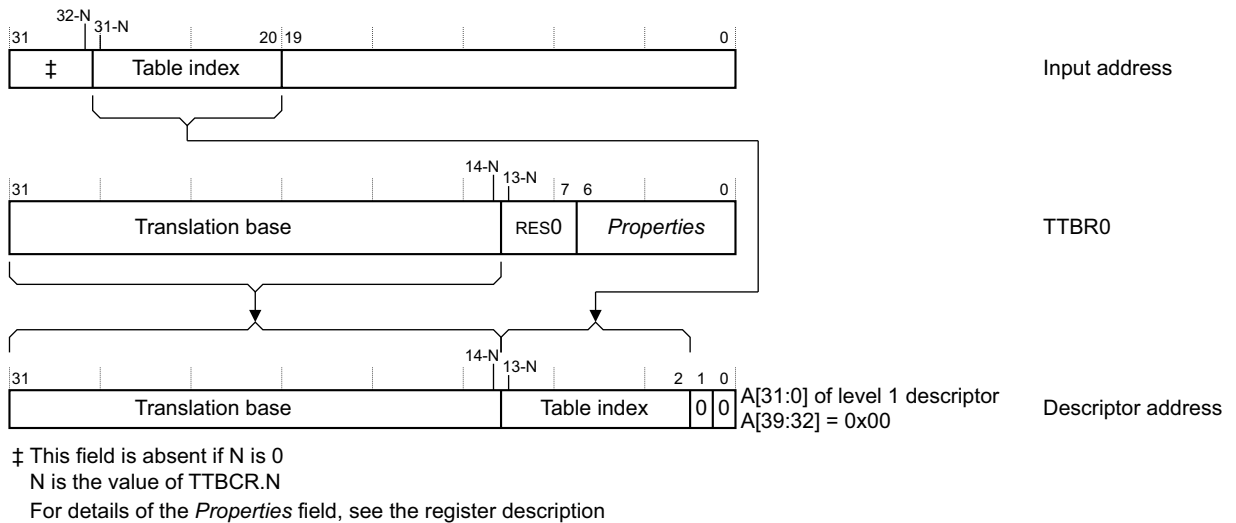

- The address bits taken from **TTBR0** vary between bits[31:14] and bits[31:7].
- The address bits taken from the VA, that is the input address for the translation, vary between bits[31:20] and bits[24:20].

The width of the **TTBR0** and VA fields depend on the value of **TTBCR.N**, as [Figure G4-7](#) shows.

When performing a fetch based on **TTBR1**, Bits **TTBR1**[31:14] are concatenated with bits[31:20] of the VA. This makes the fetch equivalent to that shown in [Figure G4-7](#), with N=0.

### Note

See *The address and Properties fields shown in the translation flows on page K6-6198* for more information about the *Properties* label used in this and other figures.

**Figure G4-7 Accessing level 1 translation table based on TTBR0, Short-descriptor format**

Regardless of which register is used as the base for the fetch, the resulting output address selects a four-byte translation table entry that is one of:

- A level 1 descriptor for a Section or Supersection.
- A descriptor for a *Page table*, that points to a level 2 translation table. In this case:
  - A second fetch is performed to retrieve a level 2 descriptor.
  - The descriptor also contains some attributes for the access, see [Figure G4-4 on page G4-4578](#).
- A faulting entry.

## The full translation flow for Sections, Supersections, Small pages and Large pages

In a translation table walk, only the initial lookup uses the translation table base address from the appropriate [TTBR](#). Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

*Address translation examples using the VMSAv8-32 Short descriptor translation table format on page K6-6193* shows the full translation flow for each of the memory section and page options. As described in *VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4577*, these options are:

**Supersection** A 16MB memory region, see *Translation flow for a Supersection on page K6-6194*.

**Section** A 1 MB memory region, see *Translation flow for a Section on page K6-6195*.

**Large page** A 64KB memory region, described by the combination of:

- A level 1 translation table entry that indicates the address of a level 2 Page table.
- A level 2 descriptor that indicates a Large page.

See *Translation flow for a Large page on page K6-6196*.

**Small page** A 4KB memory region, described by the combination of:

- A level 1 translation table entry that indicates the address of a level 2 Page table.
- A level 2 descriptor that indicates a Small page.

See *Translation flow for a Small page on page K6-6197*.

## G4.5 The VMSAv8-32 Long-descriptor translation table format

The VMSAv8-32 Long-descriptor translation table format supports the assignment of memory attributes to memory *Pages*, at a granularity of 4KB, across the complete input address range. It also supports the assignment of memory attributes to *blocks* of memory, where a block can be 2MB or 1GB.

---

**Note**

- Although the VMSAv8-32 Long-descriptor format is limited to three levels of address lookup, its design and naming conventions support extension to additional levels, to support a larger input address range.
  - Similarly, while the VMSAv8-32 implementation limits the output address range to 40 bits, its design supports extension to a larger output address range.
- 

Figure G4-2 on page G4-4563 shows the different address translation stages. The Long-descriptor translation table format:

- Is used for:
  - The Non-secure PL2 stage 1 translation.
  - The Non-secure PL1&0 stage 2 translation.
- Can be used for the Secure and Non-secure PL1&0 translations.

When used for a stage 1 translation, the translation tables support an input address of up to 32 bits, corresponding to the VA address range of the PE.

When used for a stage 2 translation, the translation tables support an input address range of up to 40 bits, to support the translation from IPA to PA. If the input address for the stage 2 translation is a 32-bit address then this address is zero-extended to 40 bits.

---

**Note**

When the Short-descriptor translation table format is used for the Non-secure stage 1 translations, this generates 32-bit IPAs. These are zero-extended to 40 bits to provide the input address for the stage 2 translation.

---

*Overview of VMSAv8-32 address translation using Long-descriptor translation tables on page G4-4586* summarizes address translation from AArch32 state when using the Long-descriptor format translation tables.

The following sections then describe the format of the descriptors in the Long-descriptor format translation tables:

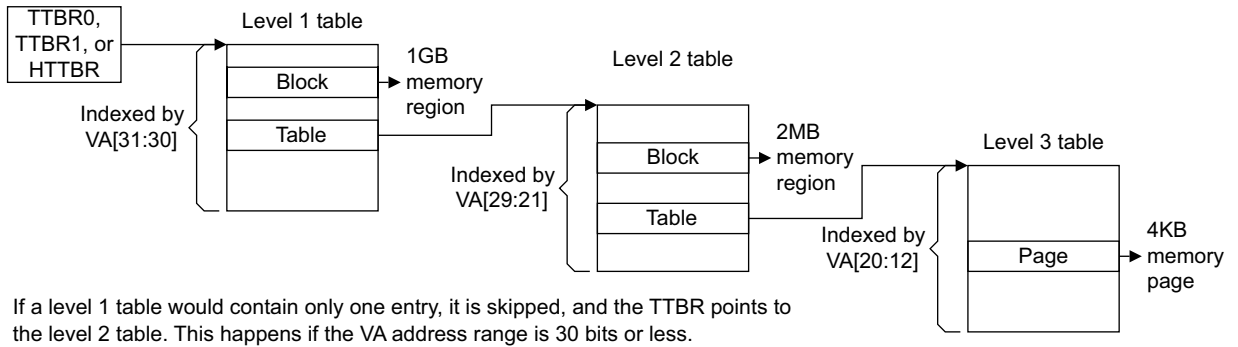

- *VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4586.*
- *Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4589.*
- *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4593.*

The following sections then describe this translation table format:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4594.*
- *VMSAv8-32 Long-descriptor translation table format address lookup levels on page G4-4597.*
- *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G4-4600.*
- *The algorithm for finding the translation table entries, VMSAv8-32 Long-descriptor format on page G4-4603.*

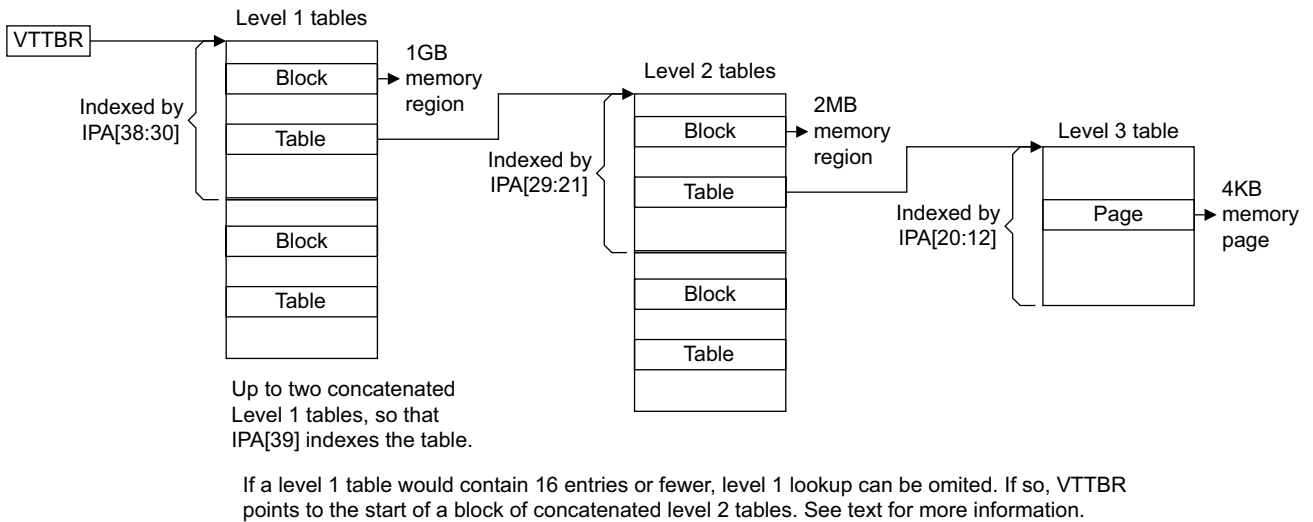

### G4.5.1 Overview of VMSAv8-32 address translation using Long-descriptor translation tables

Figure G4-8 gives a general view of VMSAv8-32 stage 1 address translation when using the Long-descriptor translation table format.

**Figure G4-8 General view of VMSAv8-32 stage 1 address translation using Long-descriptor format**

Figure G4-9 gives a general view of VMSAv8-32 stage 2 address translation. Stage 2 translation always uses the Long-descriptor translation table format.

**Figure G4-9 General view of VMSAv8-32 stage 2 address translation, Long-descriptor translation table format**

*Use of concatenated translation tables for the initial stage 2 lookup* on page G4-4597 describes how using concatenated level 2 tables means lookup can start at level 2, as referred to in Figure G4-9.

### G4.5.2 VMSAv8-32 Long-descriptor translation table format descriptors

As described in *VMSAv8-32 Long-descriptor translation table format address lookup levels* on page G4-4597, the Long-descriptor translation table provides up to three levels of address lookup. A translation table walk starts either at level 1 or level 2 of the address lookup.

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the Long-descriptor translation table descriptor formats:

- [VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats](#).
- [VMSAv8-32 Long-descriptor translation table level 3 descriptor formats on page G4-4588](#).

[Information returned by a translation table lookup on page G4-4572](#) describes the classification of the non-address fields in the descriptors between *address map control*, *access controls*, and *region attributes*.

## VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats

In the Long-descriptor translation tables, the formats of the level 1 and level 2 descriptors differ only in the size of the block of memory addressed by the block descriptor. A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

[Figure G4-10](#) shows the Long-descriptor level 1 and level 2 descriptor formats:

The level 1 descriptor returns the address of the level 2 table.

The level 2 descriptor returns the address of the level 3 table.

† See the descriptions of the address fields for more information about bits[47:40] of the Block and Table descriptors.

**Figure G4-10 VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats**

### Descriptor encodings, Long-descriptor level 1 and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- 0, Block** The descriptor gives the base address of a block of memory, and the attributes for that memory region.
- 1, Table** The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

#### Block descriptor

Gives the base address and attributes of a block of memory:

- For a level 1 Block descriptor, bits[39:30] are bits[39:30] of the output address that specifies a 1GB block of memory.
- For a level 2 Block descriptor, bits[39:21] are bits[39:21] of the output address that specifies a 2MB block of memory.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see [Address size fault on page G4-4658](#).

Bits[63:52, 11:2] provide attributes for the target memory block, see [Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4589](#). The position and contents of these bits is identical in the level 2 block descriptor and in the level 3 page descriptor.

#### Table descriptor

Bits[39:m] are bits[39:m] of the address of the required next-level table. Bits[m-1:0] of the table address are zero:

- For a level 1 Table descriptor, this is the address of a level 2 table.
- For a level 2 Table descriptor, this is the address of a level 3 table.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see [Address size fault on page G4-4658](#).

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see [Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4589](#).

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

### VMSAv8-32 Long-descriptor translation table level 3 descriptor formats

Each entry in a level 3 table describes the mapping of the associated 4KB input address range.

[Figure G4-11](#) shows the Long-descriptor level 3 descriptor formats.

<sup>‡</sup> See the description of the address field for more information about bits[47:40] of the Page descriptor.

**Figure G4-11 VMSAv8-32 Long-descriptor level 3 descriptor formats**

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

**0, Reserved, invalid**

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in level 3 translation tables.

**1, Page** Gives the address and attributes of a 4KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

**Page descriptor**

Bits[39:12] are bits[39:12] of the output address for a page of memory.

If bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see [Address size fault on page G4-4658](#).

Bits[63:52, 11:2] provide attributes for the target memory page, see [Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors](#). The position and contents of these bits are identical in the level 1 block descriptor and in the level 2 block descriptor.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

### G4.5.3 Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors

The memory attributes in the VMSAv8-32 Long-descriptor translation tables are based on those in the Short-descriptor translation table format, with some extensions. [Memory region attributes on page G4-4616](#) describes these attributes. In the Long-descriptor translation table format:

- Table entries for stage 1 translations define attributes for the next level of lookup, see [Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors](#)  
The hierarchical attributes in the translation tables, APTable, XNTable, and PXNTable, permit subtrees of the translation tables to be used by different agents. Not all operating systems use this functionality, and so ARMv8.2-AA32HPD adds a facility to disable these bits.  
This ability to disable hierarchical attribute bits has no effect on the NSTable bit.
- Block and Page entries define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:
  - [Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors on page G4-4590](#).
  - [Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors on page G4-4592](#).

#### Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the following attributes for the next-level translation table access:

- NSTable, bit[63]** For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see [Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G4-4593](#).  
 For memory accesses from Non-secure state, this bit is ignored.
- APTable, bits[62:61]** Access permissions limit for subsequent levels of lookup, see [Hierarchical control of access permissions, Long-descriptor format on page G4-4607](#).  
 APTable[0] is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.  
From ARMv8.2, when ARMv8.2-AA32HPD is implemented, this field can be disabled.

When the value of TTBCR2.HPD0 or TTBCR2.HPD1 is 1, and the value of TTBCR.T2E is also 1:

- The value of the corresponding APTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding APTable field is 0, that is to say, the APTable field has an *Effective value* of 0.

#### XNTable, bit[60]

XN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format* on page G4-4611.

From ARMv8.2, when ARMv8.2-AA32HPD is implemented, this field can be disabled.

When the value of TTBCR2.HPD0 or TTBCR2.HPD1 is 1, and the value of TTBCR.T2E is also 1:

- The value of the corresponding XNTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding XNTable field is 0, that is to say, the XNTable field has an *Effective value* of 0.

#### PXNTable, bit[59]

PXN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format* on page G4-4611.

This bit is RES0 in the Non-secure PL2 stage 1 translation tables.

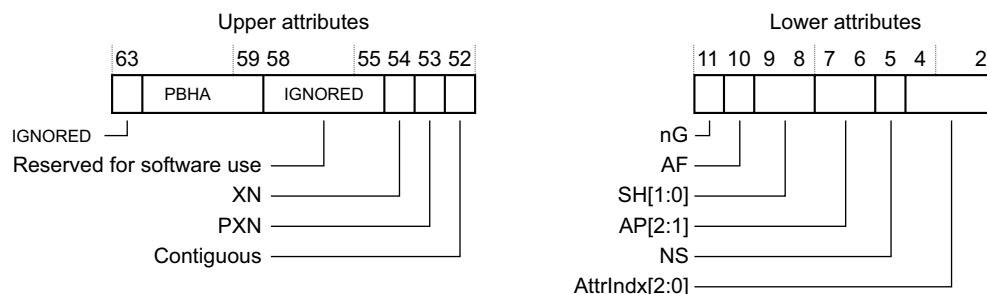

From ARMv8.2, when ARMv8.2-AA32HPD is implemented, this field can be disabled.

When the value of TTBCR2.HPD0 or TTBCR2.HPD1 is 1 and the value of TTBCR.T2E is also 1:

- The value of the corresponding PXNTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding PXNTable field is 0, that is to say, the PXNTable field has an *Effective value* of 0.

### Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block as shown for a stage 1 translation:

For a stage 1 descriptor, the attributes are:

#### PBHA, bits[62:59]

Page based hardware attributes bits.

These bits are IGNORED in descriptors at any level above level 3, and are IGNORED in level 3 descriptors in an implementation that does not include ARMv8.2-TTPBHA.

In an implementation that includes ARMv8.2-TTPBHA, the HTCR and the TTBCR2 registers both contain a control bit for each PBHA bit in the translation tables that they control. When the value of that control bit is 1, and the value of the corresponding Hierarchical permission disables bit is 1, hardware can use that PBHA bit for IMPLEMENTATION DEFINED purposes.

The control bits for this feature are:

**For a Non-secure PL2 translation regime:**

**HTCR.HWUnn**

Controls whether level 3 descriptor bit[nn] can be used by hardware.  
These controls apply only when the value of HTCR.HPD is 1.

**For a PL1&0 translation regime:**

**TTBCR2.HWU1nn**

For the translation tables indicated by TTBR1, controls whether level 3 descriptor bit[nn] can be used by hardware.  
These controls apply only when the value of TTBCR2.HPD1 is 1 and the value of TTBCR.T2E is 1.

**TTBCR2.HWU0nn**

For the translation tables indicated by TTBR0, controls whether level 3 descriptor bit[nn] can be used by hardware.  
These controls apply only when the value of TTBCR2.HPD0 is 1 and the value of TTBCR.T2E is 1.

Implementation of ARMv8.2-TTPBHA requires the implementation of ARMv8.2-AA32HPD, which provides the Hierarchical permission disables bits. If ARMv8.2-AA32HPD is implemented but ARMv8.2-TTPBHA is not implemented, then the control bits are RAZ/WI but other aspects of ARMv8.2-AA32HPD functionality are implemented. If neither feature is implemented, then:

- The control bits are RAZ/WI.
- The ARMv8.2-AA32HPD identification registers indicate that the functionality is not supported, see *ARMv8.2-AA32HPD* on page A1-61.
- The TTBCR2 register encoding is treated as unallocated.

- XN, bit[54]** The Execute-never bit. Determines whether the region is executable, see *Access permissions for instruction execution* on page G4-4609.
- PXN, bit[53]** The Privileged execute-never bit. Determines whether the region is executable at EL1, see *Access permissions for instruction execution* on page G4-4609.  
This bit is RES0 in the Non-secure PL2 stage 1 translation tables.
- Contiguous, bit[52]**  
Indicates that 16 adjacent translation table entries point to contiguous memory regions, see *Contiguous bit* on page G4-4623.
- nG, bit[11]** The not global bit. Determines how the translation is marked in the TLB, see *Global and process-specific translation table entries* on page G4-4628.  
This bit is RES0 in the Non-secure PL2 stage 1 translation tables.
- AF, bit[10]** The Access flag, see *The Access flag* on page G4-4613.
- SH, bits[9:8]** Shareability field, see *Memory region attributes* on page G4-4616.
- AP[2:1], bits[7:6]**

Access Permissions bits, see *Memory access control* on page G4-4605.

———— **Note** ————

For consistency with the Short-descriptor translation table formats, the Long-descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

AP[1] is RES1 in the Non-secure PL2 stage 1 translation tables.

- NS, bit[5]** Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in Secure or Non-secure memory, see *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format* on page G4-4593.

For memory accesses from Non-secure state, this bit is RES0 and is ignored by the PE.

#### AttrIndx[2:0], bits[4:2]

Stage 1 memory attributes index field, for the indicated Memory Attribute Indirection Register, see [VMSAv8-32 Long-descriptor format memory region attributes on page G4-4622](#).

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-6341](#). For more information about these fields see [Other fields in the Long-descriptor translation table format descriptors on page G4-4623](#).

### Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block as shown for a stage 2 translation:

\* RES0 before ARMv8.2

For a stage 2 descriptor, the attributes are:

#### PBHA, bits[62:59]

Page based hardware attributes bits.

These bits are IGNORED in descriptors at any level above level 3, and are IGNORED in level 3 descriptors in an implementation that does not include ARMv8.2-TTPBHA.

In an implementation that includes ARMv8.2-TTPBHA, the VTCR register contains a control bit for each PBHA bit in the translation tables that it controls. When the value of that control bit, VTCR.HWU<sub>nn</sub>, is 1, hardware can use the corresponding level 3 descriptor bit[nn] for IMPLEMENTATION DEFINED purposes.

Implementation of ARMv8.2-TTPBHA requires the implementation of ARMv8.2-AA32HPD. If neither feature is implemented, or if ARMv8.2-AA32HPD is implemented but ARMv8.2-TTPBHA is not implemented, then the VTCR control bits are RAZ/WI.

#### XN[1:0], bits[54:53]

The Execute-never field. Determines whether the region is executable.

For more information, see [Access permissions for instruction execution on page G4-4609](#).

In an implementation that does not support ARMv8.2-TTS2UXN, bit[53] is RES0.

#### Contiguous, bit[52]

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see [Contiguous bit on page G4-4623](#).

AF, bit[10] The Access flag, see [The Access flag on page G4-4613](#).

SH, bits[9:8] Shareability field, see [EL2 control of Non-secure memory region attributes on page G4-4624](#).

#### S2AP, bits[7:6]

Stage 2 Access Permissions bits, see [Hyp mode control of Non-secure access permissions on page G4-4614](#).

———— **Note** ————

In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

**MemAttr, bits[5:2]**

Stage 2 memory attributes, see [EL2 control of Non-secure memory region attributes on page G4-4624](#).

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-6341](#). For more information about these fields see [Other fields in the Long-descriptor translation table format descriptors on page G4-4623](#).

## **G4.5.4 Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format**

[Access to the Secure or Non-secure physical address map on page G4-4574](#) describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Long-descriptor format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, see [Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format](#).

The NS and NSTable bits are valid only for memory accesses from Secure state. Memory accesses from Non-secure state ignore the values of these bits.

### **Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format**

For Long-descriptor format table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

**NSTable == 0** The defined table address is in the Secure physical address map. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

**NSTable == 1** The defined table address is in the Non-secure physical address map. Because this table is fetched from the Non-secure address map, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:

- The value of the NS bit in any block or page descriptor is ignored. The block or page address refers to Non-secure memory.
- The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if it is read from Non-secure memory. That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see [Global and process-specific translation table entries on page G4-4628](#).

The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to NSTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

#### Note

- When using the Long-descriptor format, table descriptors are defined only for the level 1 and level 2 of lookup.
- Stage 2 translations are performed only for operations in Non-secure state, that can access only the Non-secure address map. Therefore, the stage 2 descriptors do not include NS or NSTable bits.

### G4.5.5 Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format

As described in [Determining the translation table base address in the VMSAv8-32 translation regimes on page G4-4573](#), two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and **TTBR0** and **TTBR1** hold the base addresses for the two sets of tables. The Long-descriptor translation table format provides more flexibility in defining the boundary between using **TTBR0** and using **TTBR1**. When a PL1&0 stage 1 address translation is enabled, **TTBR0** is always used. If **TTBR1** is also used then:

- **TTBR1** is used for the top part of the input address range.
- **TTBR0** is used for the bottom part of the input address range.

The **TTBCR.T0SZ** and **TTBCR.T1SZ** size fields control the use of **TTBR0** and **TTBR1**, as [Table G4-2](#) shows.

**Table G4-2 Use of TTBR0 and TTBR1, Long-descriptor format**

TTBCR		Input address range using:	
T0SZ	T1SZ	TTBR0	TTBR1
0b000	0b000	All addresses	Not used
$M^a$	0b000	Zero to $(2^{(32-M)}-1)$	$2^{32-M}$ to maximum input address
0b000	$N^a$	Zero to $(2^{32-2(32-N)}-1)$	$2^{32-2(32-N)}$ to maximum input address
$M^a$	$N^a$	Zero to $(2^{(32-M)}-1)$	$2^{32-2(32-N)}$ to maximum input address

a.  $M, N$  must be greater than 0. The maximum possible value for each of T0SZ and T1SZ is 7.

For stage 1 translations, the input address is always a VA, and the maximum possible VA is  $(2^{32}-1)$ .

When address translation is using the Long-descriptor translation table format:

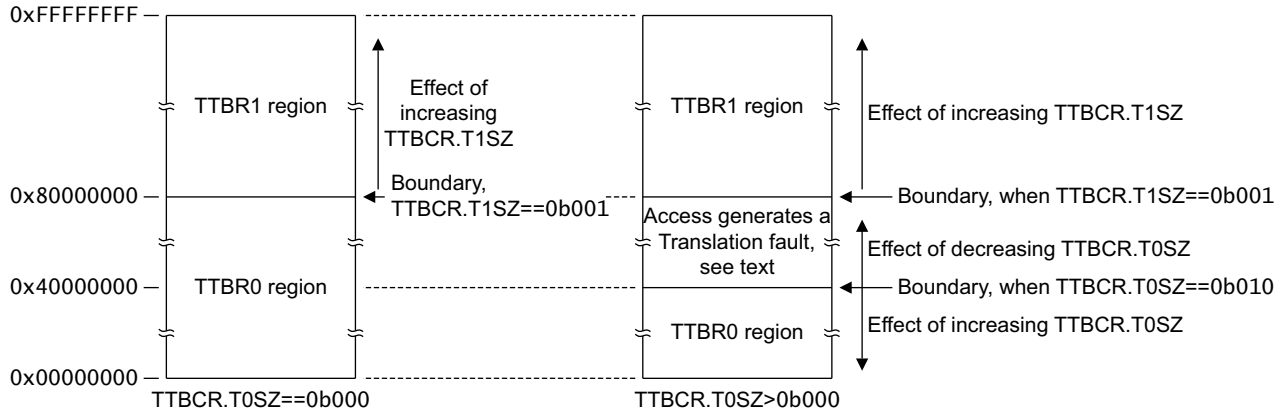

- [Figure G4-12](#) shows how, when **TTBCR.T1SZ** is zero, the value of **TTBCR.T0SZ** controls the boundary between VAs that are translated using **TTBR0**, and VAs that are translated using **TTBR1**.

**Figure G4-12 Control of TTBR boundary, when TTBCR.T1SZ is zero**

- Figure G4-13 shows how, when **TTBCR.T1SZ** is nonzero, the values of **TTBCR.T0SZ** and **TTBCR.T1SZ** control the boundaries between VAs that are translated using **TTBR0**, and VAs that are translated using **TTBR1**.

**Figure G4-13 Control of TTBR boundaries, when **TTBCR.T1SZ** is nonzero**

When **T0SZ** and **T1SZ** are both nonzero:

- If both fields are set to **0b001**, the boundary between the two regions is **0x80000000**. This is identical to having **T0SZ** set to **0b000** and **T1SZ** set to **0b001**.
- Otherwise, the **TTBR0** and **TTBR1** regions are non-contiguous. In this case, any attempt to access an address that is in that gap between the **TTBR0** and **TTBR1** regions generates a Translation fault.

**Note**

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the **TCR\_EL1.TnSZ** values and the region for which an access generates a Translation fault is wider than shown in Figure G4-13. That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. [Possible errors in programming the translation table registers](#) describes this possibility.

When using the Long-descriptor translation table format:

- The **TTBCR** contains fields that define memory region attributes for the translation table walk, for each **TTBR**. These are the **SH0**, **ORGN0**, **IRGN0**, **SH1**, **ORGN1**, and **IRGN1** bits.
- TTBR0** and **TTBR1** each contain an **ASID** field, and the **TTBCR.A1** field selects which **ASID** to use.

For this translation table format, [VMSAv8-32 Long-descriptor translation table format address lookup levels](#) on page G4-4597 summarizes the lookup levels, and [Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format](#) on page G4-4600 describes the possible translations.

### Possible errors in programming the translation table registers

In all the descriptions in this subsection, the *size of the input address* supported for a PL1&0 stage 1 translation refers to the size specified by a **TTBCR.TxSZ** field.

**Note**

For a PL1&0 stage 1 translation, the input address range can be split so that the lower addresses are translated by **TTBR0** and the higher addresses are translated by **TTBR1**. In this case, each of input address sizes specified by **TTBCR.{T0SZ, T1SZ}** is smaller than the total address size supported by the stage of translation.

The following are possible errors in the programming of **TTBR0**, **TTBR1**, and **TTBCR**. For the translation of a particular address at a particular stage of translation, either:

- The block size being used to translate the address is larger than the size of the input address supported at a stage of translation used in performing the required translation. This can occur only for the PL1&0 stage 1 translations, and only when either **TTBCR.T0SZ** or **TTBCR.T1SZ** is zero, meaning there is no gap between the address range translated by **TTBR0** and the range translated by **TTBR1**. In this case, this programming error occurs if a block translated from the region that has TxSZ set to zero straddles the boundary between the two address ranges. [Example G4-2](#) shows an example of this mis-programming.
- The address range translated by a set of blocks marked as contiguous, by use of the contiguous bit, is larger than the size of the input address supported at a stage of translation used in performing the required translation.

#### Example G4-2 Error in programming the translation table registers

If **TTBCR.T0SZ** is programmed to 0 and **TTBCR.T1SZ** is programmed to 7, this means:

- **TTBR0** translates addresses in the range 0x00000000-0xFDFFFFFF.
- **TTBR1** translates addresses in the range 0xFE000000-0xFFFFFFFF.

The translation table indicated by **TTBR0** might be programmed with a block entry for a 1GB region starting at 0xC0000000. This covers the address range 0xC0000000-0xFFFFFFFF, that overlaps the **TTBR1** address range. This means this block size is larger than the input address size supported for translations using **TTBR0**, and therefore this is a programming error.

To understand why this must be a programming error, consider a memory access to address 0xFFFF0000. According to the **TTBCR.T0SZ, T1SZ** values, this must be translated using **TTBR1**. However, the access matches a TLB entry for the translation, using **TTBR0**, of the block at 0xC0000000. Hardware is not required to detect that the access to 0xFFFF0000 is being translated incorrectly.

In these cases, an implementation might use one of the following approaches:

- Treat such a block as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation.  
The block might be a block within a contiguous set of blocks.
- Treat such a block as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.
The block might be a block within a contiguous set of blocks.

Additional constraints apply to programming the **VTCR**, see [Determining the required initial lookup level for stage 2 translations on page G4-4602](#).

## G4.5.6 VMSAv8-32 Long-descriptor translation table format address lookup levels

As stated at the start of this section, because the Long-descriptor translation table format is used for the Non-secure PL1&0 stage 2 translations, the format must support input addresses of up to 40 bits.

Table G4-3 summarizes the properties of the different levels of address lookup when using this format.

**Table G4-3 Properties of the three levels of address lookup with VMSAv8-32 Long-descriptor translation tables**

Level	Input address		Output address <sup>a</sup>		Number of entries
	Size	Address range <sup>b</sup>	Size	Address range	
First	Up to 512GB	Up to Address[38:0]	1GB	Address[39:30]	Up to 512
Second	Up to 1GB	Up to Address[29:0]	2MB	Address[39:21]	Up to 512
Third	2MB	Address[20:0]	4KB	Address[39:12]	512

a. Output address when an entry addresses a block of memory or a memory page. If an entry addresses the next level of address lookup it specifies Address[39:12] for the next-level translation table.

b. Input address range for the translation table. See *Use of concatenated level 1 translation tables* on page G4-4598 for details of support for additional bits of address at a given level, including possible support of a 40-bit input address range for stage 2 translations at level 1. For stage 1 translations at level 1 the input address range is limited to the VA size of [31:0].

For level 1 and level 2 tables, reducing the input address range reduces the number of addresses in the table and therefore reduces the table size. The appropriate Translation Table Control Register specifies the input address range.

Stage 1 translations require an input address range of up to 32 bits, corresponding to VA[31:0]. For these translations:

- For a memory access from a mode other than Hyp mode, the Secure or Non-secure **TTBR0** or **TTBR1** holds the translation table base address, and the Secure or Non-secure **TTBCR** is the control register.
- For a memory access from Hyp mode, **HTTBR** holds the translation table base address, and **HTTCR** is the control register.

### **Note**

For translations controlled by **TTBR0** and **TTBR1**, if neither **TTBR** has an input address range larger than 1GB, then translation starts at level 2. Together, **TTBR0** and **TTBR1** can still cover the 32-bit VA input address range.

Stage 2 translations require an input address range of up to 40 bits, corresponding to IPA[39:0], and the supported input address size is configurable in the range 25-40 bits. Table G4-3 indicates a requirement for the translation mechanism to support a 39-bit input address range, Address[38:0]. *Use of concatenated translation tables for the initial stage 2 lookup* describes how a 40-bit IPA address range is supported. For stage 2 translations:

- **VTTBR** holds the translation table base address, and **VTTCR** is the control register.
- If a supplied input address is larger than the configured input address size, a Translation fault is generated.

## **Use of concatenated translation tables for the initial stage 2 lookup**

If a stage 2 translation would require 16 entries or fewer in its top-level translation table, that stage of translation can, instead, be configured so that:

- It requires the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- The stage 2 translation starts at that next translation level.

---

**Note**

---

Stage 2 translations always use the Long-descriptor translation table format.

---

This use of concatenated translation tables is:

- Required when the stage 2 translation supports a 40-bit input address range, see [Use of concatenated level 1 translation tables](#).
- Supported for a stage 2 translation with an input address range of 31-34 bits, see [Use of concatenated level 2 translation tables](#).

The use of concatenated translation tables requires the software that is defining the translation to:

- Define the concatenated translation tables with the required overall alignment.
- Program [VTTBR](#) to hold the address of the first of the concatenated translation tables.
- Program [VTCR](#) to indicate the required input address range and initial lookup level.

---

**Note**

---

The use of concatenated translation tables avoids the overhead of an additional level of translation

---

**Use of concatenated level 1 translation tables**

The Long-descriptor format translation tables provide 9 bits of address resolution at each level of lookup. However, a 40-bit input address range with a translation granularity of 4KB requires a total of 28 bits of address resolution. Therefore, a stage 2 translation that supports a 40-bit input address range requires two concatenated level 1 translation tables, together aligned to 8KB, where:

- The table at the address with  $PA[12:0] == 0b0\_0000\_0000\_0000$  defines the translations for input addresses with  $bit[39] == 0$ .
- The table at the address with  $PA[12:0] == 0b1\_0000\_0000\_0000$  defines the translations for input addresses with  $bit[39] == 1$ .
- The 8KB alignment requirement means that both tables have the same value for  $PA[39:13]$ .

**Use of concatenated level 2 translation tables**

A stage 2 translation with an input address range of 31-34 bits can start the translation either:

- With a level 1 lookup, accessing a level 1 translation table with 2-16 entries.
- With a level 2 lookup, accessing a set of concatenated level 2 translation tables.

[Table G4-4 on page G4-4599](#) shows these options, for each of the input address ranges that can use this scheme.

---

**Note**

---

Because these are stage 2 translations, the input address range is an IPA range.

---

**Table G4-4 Possible uses of concatenated translation tables for level 2 lookup**

Input address range		Lookup starts at level 1	Lookup starts at level 2	
IPA range	Size	Required level 1 entries	Number of concatenated tables	Required alignment <sup>a</sup>
IPA[30:0]	2 <sup>31</sup> bytes	2	2	8KB
IPA[31:0]	2 <sup>32</sup> bytes	4	4	16KB
IPA[32:0]	2 <sup>33</sup> bytes	8	8	32KB
IPA[33:0]	2 <sup>34</sup> bytes	16	16	64KB

a. Required alignment of the set of concatenated level 2 tables.

See also [Determining the required initial lookup level for stage 2 translations](#) on page G4-4602.

## G4.5.7 Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format

Figure G4-2 on page G4-4563 shows the possible address translations. If a stage of translation is controlled from an Exception level that is using AArch32, the input and output address constraints and the registers that control the translation are as follows:

### Stage 1 translations

For all stage 1 translations:

- The input address range is up to 32 bits, as determined by either:
  - [TTBCR.T0SZ](#) or [TTBCR.T1SZ](#), for a PL1&0 stage 1 translation.
  - [HTCR.T0SZ](#), for a PL2 stage 1 translation.
- The output address range is 40 bits.

The stage 1 translations are:

#### Non-secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Non-secure modes other than Hyp mode. This translates a VA to an IPA. For this translation, when Non-secure EL1 is using AArch32:

- Non-secure [TTBR0](#) or [TTBR1](#) holds the translation table base address.
- Non-secure [TTBCR](#) determines which TTBR is used.

#### Non-secure PL2 stage 1 translation

The stage 1 translation for memory accesses from Hyp mode, translates a VA to a PA. For this translation, when EL2 is using AArch32, [HTTBR](#) holds the translation table base address.

#### Secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Secure modes, translates a VA to a PA. For this translation, when the Secure PL1 modes are using AArch32:

- Secure [TTBR0](#) or [TTBR1](#) holds the translation table base address.
- Secure [TTBCR](#) determines which TTBR is used.

### Stage 2 translation

#### Non-secure PL1&0 stage 2 translation

The stage 2 translation for memory accesses from Non-secure modes other than Hyp mode, and translates an IPA to a PA. For this translation, when EL2 is using AArch32:

- The input address range is 40 bits, and [VTCR.T0SZ](#) determines the input address size.
- The output address range depends on the implemented memory system, and is up to 40 bits.
- [VTTBR](#) holds the translation table base address.
- [VTCR](#) specifies the required input address range, and whether the initial lookup is at level 1 or at level 2.

The descriptions of the VMSAv8-32 translation stages state that the maximum output address size is 40 bits. However, the register and Long-descriptor format descriptor fields that hold these addresses are 48 bits wide. If bits[47:40] of an output address are not all zero then the address generates an Address size fault.

The Long-descriptor translation table format provides up to three levels of address lookup, as described in [VMSAv8-32 Long-descriptor translation table format address lookup levels on page G4-4597](#), and the initial lookup, in which the MMU reads the translation table base address, is at either level 1 or level 2. The following determines the level of the initial lookup:

- For a stage 1 translation, the required input address range. For more information see [Determining the required initial lookup level for stage 1 translations on page G4-4602](#).
- For a stage 2 translation, the level specified by the [VTCR.SL0](#) field. For more information see [Determining the required initial lookup level for stage 2 translations on page G4-4602](#).

**Note**

For a stage 2 translation, the size of the required input address range constrains the [VTCR.SL0](#) value.

Figure G4-14 shows how the descriptor address for the initial lookup for a translation using the Long-descriptor translation table format is determined from the input address and the [TTBR](#) value. This figure shows the lookup for a translation that starts with a level 1 lookup, that translates bits[39:30] of the input address, zero extended if necessary.

See text for more information about the translation table base register used, and the value of  $n$ .

‡ This field is absent if  $n$  is 13.

† For a Non-secure PL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

§ See the lookup description for more information about bits[40:47] of the TTBR

**Figure G4-14 VMSAv8-32 Long-descriptor initial lookup, starting at level 1**

If bits[47:40] of the [TTBR](#) are not zero then the initial lookup will generate an Address size fault, see [Address size fault](#) on page G4-4658.

For a translation that starts with a level 1 lookup, as shown in [Figure G4-14](#):

**For a stage 1 translation**

$n$  is in the range 4-5 and:

- For a memory access from Hyp mode:
  - [HTTBR](#) is the [TTBR](#).
  - $n=5-(\text{HTCR.T0SZ})$ .
- For other accesses:
  - The Secure or Non-secure instance of [TTBR0](#) or [TTBR1](#) is the [TTBR](#).
  - $n=(5-\text{TTBCR.TxSZ})$ , where  $x$  is 0 when using [TTBR0](#), and 1 when using [TTBR1](#).

**For a stage 2 translation**

$n$  is in the range 4-13 and:

- [VTTBR](#) is the [TTBR](#).
- $n=5-(\text{VTCR.T0SZ})$ .

For a translation that starts with a level 2 lookup, the descriptor address is obtained in the same way, except that bits[(n+17):21] of the input address provide bits[(n-1):3] of the descriptor address, where:

**For a stage 1 translation**

$n$  is in the range 7-12. As [Determining the required initial lookup level for stage 1 translations](#) shows, for a stage 1 translation to start with a level 2 lookup, the corresponding T0SZ or T1SZ field must be 2 or more. This means:

- For a memory access from Hyp mode,  $n=14-HTCR.T0SZ$ .
- For other memory accesses,  $n=14-(TTBCR.TxSZ)$ , where  $x$  is 0 when using [TTBR0](#), and 1 when using [TTBR1](#).

**For a stage 2 translation**

$n$  is in the range 7-16. For a stage 2 translation to start with a level 2 lookup, [VTCR.SL0](#) is 0b00, and  $n=14-(VTCR.T0SZ)$ .

The following sections describe how the level of the initial lookup is determined:

- [Determining the required initial lookup level for stage 1 translations](#).
- [Determining the required initial lookup level for stage 2 translations](#).

[Address translation examples using the VMSAv8-32 Long descriptor translation table format on page K6-6198](#) shows examples of full translation flows, to an entry for a 4KB memory page, for lookups starting at level 1 and lookups starting at level 2.

**Determining the required initial lookup level for stage 1 translations**

For a stage 1 translation, the required input address range, indicated by a T0SZ or T1SZ field in a translation table control register, determines the initial lookup level. The size of this input address region is  $2^{(32-TxSZ)}$  bytes, and if this size is:

- Less than or equal to  $2^{30}$  bytes, the required start is at level 2, and translation requires two levels of table to map to 4KB pages. This corresponds to a TxSZ value of 2 or more.
- More than  $2^{30}$  bytes, the required start is at level 1, and translation requires three levels of table to map to 4KB pages. This corresponds to a TxSZ value that is less than 2.

For the PL1&0 stage 1 translations, the [TTBCR](#):

- Splits the 32-bit VA input address range between [TTBR0](#) and [TTBR1](#), see [Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4594](#).
- Holds the input address range sizes for [TTBR0](#) and [TTBR1](#), in the [TTBCR.T0SZ](#) and [TTBCR.T1SZ](#) fields.

For the PL2 stage 1 translations, [HTCR.T0SZ](#) indicates the size of the required input address range. For example, if this field is 0b000, it indicates a 32-bit VA input address range, and translation lookup must start at level 1.

**Determining the required initial lookup level for stage 2 translations**

For a PL1&0 stage 2 translation, the output address range from the PL1&0 stage 1 translations determines the required input address range for the stage 2 translation.

[VTCR.SL0](#) indicates the starting level for the lookup. The permitted SL0 values are:

0b00	Stage 2 translation lookup must start at level 2.
0b01	Stage 2 translation lookup must start at level 1.

In addition, [VTCR.T0SZ](#) must indicate the required input address range. The size of the input address region is  $2^{(32-T0SZ)}$  bytes.

———— **Note** ————

**VTCR.T0SZ** holds a four-bit signed integer value, meaning it supports values from -8 to 7. This is different from the other translation control registers, where **TnSZ** holds a three-bit unsigned integer, supporting values from 0 to 7.

The programming of **VTCR** must follow the constraints shown in [Table G4-5](#), otherwise any attempt to perform a translation table walk that uses the stage 2 address translation generates a stage 2 level 1 Translation Fault. The table also shows how the **VTCR.SL0** and **VTCR.T0SZ** values determine the **VTBTR.BADDR** field width.

———— **Note** ————

If **VTCR.SL0** is programmed to a reserved value then the constraints shown in [Table G4-5](#) are not met, and a translation table walk that uses stage 2 translation generates a stage 2 level 1 Translation fault.

**Table G4-5 Input address range constraints on programming **VTCR****

<b>VTCR.SL0</b>	<b>VTCR.T0SZ</b>	Input address range, R	Initial lookup level	<b>BADDR</b> [39:x] width <sup>a</sup>
0b00	2 to 7	$R \leq 2^{30}$ bytes	Level 2	[39:12] to [39:7]
0b00	-2 to 1	$2^{30} < R \leq 2^{34}$ bytes	Level 2	[39:16] to [39:13]
0b01	-2 to 1		Level 1	[39:7] to [39:4]
0b01	-8 to -3	$2^{34} < R$	Level 1	[39:13] to [39:8]

a. The first range corresponds to the first T0SZ value, the second range to the second T0SZ value.

In addition, **VTCR.S** must be programmed to the value of **T0SZ**[3], otherwise behavior is CONSTRAINED UNPREDICTABLE with the resulting behavior being that **VTCR.T0SZ** is treated as an UNKNOWN value.

———— **Note** ————

**VTCR.T0SZ** being treated as an UNKNOWN value results in a stage 2 level 1 Translation Fault if that UNKNOWN value is not consistent with the programmed value of **VTCR.SL0**.

*CONSTRAINED UNPREDICTABLE behaviors associated with the **VTCR** on page K1-6114* describes these CONSTRAINED UNPREDICTABLE behaviors.

Where necessary, the initial lookup level provides multiple concatenated translation tables, as described in *Use of concatenated level 2 translation tables on page G4-4598*. This section also gives more information about the alternatives, shown in [Table G4-5](#), when R is in the range  $2^{31} - 2^{34}$ .

## G4.5.8 The algorithm for finding the translation table entries, VMSAv8-32 Long-descriptor format

This section gives the algorithm for finding the translation table entry that corresponds to a given IA, for each required level of lookup. The algorithm encodes the descriptions of address translation given earlier in this section. The VMSAv8-32 Long-descriptor format uses a 4KB translation granule.

The description uses the following terms:

- BaseAddr** The base address for the level of lookup, as defined by:
- For the initial lookup level, the **TTBR.BADDR** base address field in the appropriate **TTBR**, see the description of **TnSZ** on page G4-4604.
  - Otherwise, the translation table address returned by the previous level of lookup.
- IA** The supplied IA for this stage of translation.

- TnSZ** The translation table size for this stage of translation:
- For PL1&0 stage 1** Either:
- **TTBCR.T0SZ** if the translation is using **TTBR0**.
  - **TTBCR.T1SZ** if the translation is using **TTBR1**.
- For PL1&0 stage 2** **VTBR.T0SZ**. The translation uses **VTBR**.
- For PL2 stage 1** **HTCR.T0SZ**. The translation uses **HTTBR**.
- SL0** **VTBR.SL0**. Applies to the Non-secure PL1&0 stage 2 translation only.

Table G4-6 shows the translation table descriptor address, for each level of lookup. The table shows only architecturally-valid programming of the **TCR**. See also *Possible errors in programming the translation table registers* on page G4-4595.

**Table G4-6 Translation table entry addresses, VMSAv8-32 using Long-descriptor format**

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	Stage 2 translation	
One	BaseAddr[39:x]:IA[y:30]:0b000 if <sup>a</sup> $0 \leq TnSZ \leq 1$ then $x = (5 - TnSZ)$	BaseAddr[39:x]:IA[y:30]:0b000 if $SL0^b = 1$ then if <sup>a</sup> $-8 \leq T0SZ \leq 1$ then $x = (5 - T0SZ)$	$y = (x + 26)$
Two	BaseAddr[39:x]:IA[y:21]:0b000 if <sup>a</sup> $2 \leq TnSZ \leq 7$ then $x = (14 - TnSZ)$  else <sup>c</sup> $x = 12$	BaseAddr[39:x]:IA[y:21]:0b000 if $SL0 = 0$ then if <sup>a</sup> $-2 \leq T0SZ \leq 7$ then $x = (14 - T0SZ)$ elseif <sup>c</sup> $SL0^b = 1$ then $x = 12$	$y = (x + 17)$
Three	BaseAddr[39:12]:IA[20:12]:0b000	BaseAddr[39:12]:IA[20:12]:0b000	-

- a. This line indicates the range of permitted values for **TnSZ**, for a lookup that starts at this level, see *Use of concatenated translation tables for the initial stage 2 lookup* on page G4-4597.
- b.  $SL0 = 0$  if the initial lookup is level 2,  $SL0 = 1$  if the initial lookup is level 1.
- c. This is the case where this level of lookup is not the initial level of lookup.

## G4.6 Memory access control

In addition to an output address, a translation table entry that refers to page or region of memory includes fields that define properties of the target memory region. [Information returned by a translation table lookup on page G4-4572](#) describes the classification of those fields as address map control, access control, and memory attribute fields. The access control fields, described in this section, determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- [About access permissions.](#)
- [About the PAN bit on page G4-4608.](#)
- [Access permissions for instruction execution on page G4-4609.](#)
- [Domains, Short-descriptor format only on page G4-4612.](#)
- [The Access flag on page G4-4613.](#)
- [Hyp mode control of Non-secure access permissions on page G4-4614.](#)

### G4.6.1 About access permissions

The translation table descriptors include fields that define access permissions for data accesses and for instruction fetches. This section introduces those fields. In addition:

- System register controls can prevent execution from writeable locations, see [Preventing execution from writeable locations on page G4-4612.](#)
- In ARMv8.1, the `PSTATE.PAN` can affect the access permissions for privileged data accesses, see [About the PAN bit on page G4-4608.](#)

#### ———— Note ————

This section gives a general description of memory access permissions. Software executing at PL1 in Non-secure state can see only the access permissions defined by the Non-secure PL1&0 stage 1 translations. However, software executing at PL2 can modify these permissions, as described in [Hyp mode control of Non-secure access permissions on page G4-4614](#). This modification is invisible to Non-secure software executing at EL1 or EL0.

Access permission bits in a translation table descriptor control access to the corresponding memory region. The details of this control depend on the translation table format, as follows:

#### Short-descriptor format

This format supports two options for defining the access permissions:

- Three bits, `AP[2:0]`, define the access permissions.
- Two bits, `AP[2:1]`, define the access permissions, and `AP[0]` can be used as an Access flag.

`SCTLR.AFE` selects the access permissions option. Setting this bit to 1, to enable the Access flag, also selects use of `AP[2:1]` to define access permissions.

ARM deprecates any use of the `AP[2:0]` scheme for defining access permissions.

#### Long-descriptor format

`AP[2:1]` to control the access permissions, and the descriptors provide an AF bit for use as an Access flag. This means VMSAv8-32 behaves as if the value of `SCTLR.AFE` is 1, regardless of the value that software has written to this bit.

#### ———— Note ————

When use of the Long-descriptor format is enabled, `SCTLR.AFE` is UNK/SBOP.

[The Access flag on page G4-4613](#) describes the Access flag, for both translation table formats.

The XN and PXN bits provide additional access controls for instruction fetches, see [Access permissions for instruction execution on page G4-4609.](#)

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation. However, when using the Short-descriptor translation table format, it generates the fault only if the access is to memory in the Client domain, see [Domains, Short-descriptor format only on page G4-4612](#).

#### ————— Note —————

For the Non-secure PL1&0 translation regime, memory accesses are subject to two stages of translation. Each stage of translation has its own, independent, fault checking. Fault handling is different for the two stages, see [Exception reporting in a VMSAv8-32 implementation on page G4-4663](#).

The following sections describe the two access permissions models:

- [AP\[2:1\] access permissions model](#).
- [AP\[2:0\] access permissions control, Short-descriptor format only on page G4-4607](#). This section includes some information on access permission control in earlier versions of the ARM VMSA.

### AP[2:1] access permissions model

#### ————— Note —————

ARM recommends that this model is always used, even where the AP[2:0] model is permitted. Some documentation describes the AP[2:1] model as the *simplified access permissions* model.

This access permissions model is used if the translation is either:

- Using the Long-descriptor translation table format.
- Using Short-descriptor translation table format, and the [SCTLR.AFE](#) bit is set to 1.

In this model:

- One bit, AP[2], selects between read-only and read/write access.
- A second bit, AP[1], selects between Application level (PL0) and System level (PL1) control.  
For the Non-secure PL2 stage 1 translations, AP[1] is SBO.

This provides four access combinations:

- Read-only at all privilege levels.
- Read/write at all privilege levels.
- Read-only at PL1, no access by software executing at PL0.
- Read/write at PL1, no access by software executing at PL0.

[Table G4-7](#) shows this access control model.

**Table G4-7 VMSAv8-32 AP[2:1] access permissions model**

AP[2], disable write access	AP[1], enable unprivileged access	Access
0	0 <sup>a</sup>	Read/write, only at PL1
0	1	Read/write, at any privilege level
1	0 <sup>a</sup>	Read-only, only at PL1
1	1	Read-only, at any privilege level

a. Not valid for Non-secure PL2 stage 1 translation tables. AP[1] is SBO in these tables.

**Hierarchical control of access permissions, Long-descriptor format**
