#### Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '10' UnallocatedEncoding();
    when '11'
        if HaveFP16Ext() then
            datasize = 16;
        else
            UnallocatedEncoding();

FPRounding rounding;
rounding = FPDecodeRounding('11');
```

#### Assembler symbols

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Hd>	Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn>	Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sn>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

## Operation

```
CheckFPAdvSIMDEnabled64();  
  
bits(datasize) result;  
bits(datasize) operand = V[n];  
  
result = FPRoundInt(operand, FPCR, rounding, FALSE);  
  
V[d] = result;
```

## C7.2.144 FRSQRTE

Floating-point Reciprocal Square Root Estimate. This instruction calculates an approximate square root for each vector element in the source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#) or a synchronous exception being generated. For more information, see [Floating-point exceptions and exception traps on page D1-1831](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Assembler symbols

<i>&lt;Hd&gt;</i>	Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<i>&lt;Hn&gt;</i>	Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<i>&lt;V&gt;</i>	Is a width specifier, encoded in the "sz" field. It can have the following values: S           when sz = 0 D           when sz = 1
<i>&lt;d&gt;</i>	Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<i>&lt;n&gt;</i>	Is the number of the SIMD&FP source register, encoded in the "Rn" field.
<i>&lt;Vd&gt;</i>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<i>&lt;T&gt;</i>	For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values: 4H           when Q = 0 8H           when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S            when sz = 0, Q = 0

4S            when sz = 0, Q = 1

2D            when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn>            Is the name of the SIMD&FP source register, encoded in the "Rn" field.

## Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPRSqrtEstimate(element, FPCR);

V[d] = result;
```

## C7.2.145 FRSQRTS

Floating-point Reciprocal Square Root Step. This instruction multiplies corresponding floating-point values in the vectors of the two source SIMD&FP registers, subtracts each of the products from 3.0, divides these results by 2.0, places the results into a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#), or a synchronous exception being generated. For more information, see [Floating-point exceptions and exception traps on page D1-1831](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Hm>	Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();  
bits(datasize) result;  
bits(datasize) operand1 = V[n];  
bits(datasize) operand2 = V[m];  
  
result = FPSub(operand1, operand2, FPCR);  
V[d] = result;
```

## C7.2.150 INS (element)

Insert vector element from another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias [MOV \(element\)](#). The alias is always the preferred disassembly.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	11	10	9	5	4	0
0	1	1	0	1	1	1	0	0	0	0	0	imm5	0	imm4	1	Rn	Rd			

### Advanced SIMD variant

INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer dst_index = UInt(imm5<4:size+1>);
integer src_index = UInt(imm4<3:size>);
integer idxsize = if imm4<3> == '1' then 128 else 64;
// imm4<size-1:0> is IGNORED

integer esize = 8 << size;
```

### Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.								
<Ts>	Is an element size specifier, encoded in the "imm5" field. It can have the following values: <table> <tr> <td>B</td><td>when imm5 = xxxx1</td></tr> <tr> <td>H</td><td>when imm5 = xxx10</td></tr> <tr> <td>S</td><td>when imm5 = xx100</td></tr> <tr> <td>D</td><td>when imm5 = x1000</td></tr> </table> The encoding imm5 = x0000 is reserved.	B	when imm5 = xxxx1	H	when imm5 = xxx10	S	when imm5 = xx100	D	when imm5 = x1000
B	when imm5 = xxxx1								
H	when imm5 = xxx10								
S	when imm5 = xx100								
D	when imm5 = x1000								
<index1>	Is the destination element index encoded in the "imm5" field. It can have the following values: <table> <tr> <td>imm5&lt;4:1&gt;</td><td>when imm5 = xxxx1</td></tr> <tr> <td>imm5&lt;4:2&gt;</td><td>when imm5 = xxx10</td></tr> <tr> <td>imm5&lt;4:3&gt;</td><td>when imm5 = xx100</td></tr> <tr> <td>imm5&lt;4&gt;</td><td>when imm5 = x1000</td></tr> </table> The encoding imm5 = x0000 is reserved.	imm5<4:1>	when imm5 = xxxx1	imm5<4:2>	when imm5 = xxx10	imm5<4:3>	when imm5 = xx100	imm5<4>	when imm5 = x1000
imm5<4:1>	when imm5 = xxxx1								
imm5<4:2>	when imm5 = xxx10								
imm5<4:3>	when imm5 = xx100								
imm5<4>	when imm5 = x1000								
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.								

<index2> Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

- imm4<3:0> when imm5 = xxxx1
- imm4<3:1> when imm5 = xxx10
- imm4<3:2> when imm5 = xx100
- imm4<3> when imm5 = x1000

The encoding imm5 = x0000 is reserved.

Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(idxsize) operand = V[n];
bits(128) result;

result = V[d];
Elem[result, dst_index, esize] = Elem[operand, src_index, esize];
V[d] = result;
```

## C7.2.151 INS (general)

Insert vector element from general-purpose register. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias [MOV \(from general\)](#). The alias is always the preferred disassembly.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	1	0	0	1	1	1	0	0	0	0	0	imm5	0	0	0	1	1	1	Rn	Rd		

### Advanced SIMD variant

INS <Vd>.<Ts>[<index>], <R><n>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);

if size > 3 then UnallocatedEncoding();
integer index = UInt(imm5<4:size+1>);

integer esize = 8 << size;
integer datasize = 128;
```

### Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ts>	Is an element size specifier, encoded in the "imm5" field. It can have the following values: <div> <div>B</div> <div>when imm5 = xxxx1</div> <div>H</div> <div>when imm5 = xxx10</div> <div>S</div> <div>when imm5 = xx100</div> <div>D</div> <div>when imm5 = x1000</div> </div> The encoding imm5 = x0000 is reserved.
<index>	Is the element index encoded in the "imm5" field. It can have the following values: <div> <div>imm5&lt;4:1&gt;</div> <div>when imm5 = xxxx1</div> <div>imm5&lt;4:2&gt;</div> <div>when imm5 = xxx10</div> <div>imm5&lt;4:3&gt;</div> <div>when imm5 = xx100</div> <div>imm5&lt;4&gt;</div> <div>when imm5 = x1000</div> </div> The encoding imm5 = x0000 is reserved.
<R>	Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values: <div> <div>W</div> <div>when imm5 = xxxx1</div> </div>

W            when imm5 = xxx10

W            when imm5 = xx100

X            when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<n>            Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

## Operation

```
CheckFPAdvSIMDEnabled64();  
bits(esize) element = X[n];  
bits(datasize) result;  
  
result = V[d];  
Elem[result, index, esize] = element;  
V[d] = result;
```

## C7.2.152 LD1 (multiple structures)

Load multiple single-element structures to one, two, three, or four registers. This instruction loads multiple single-element structures from memory and writes the result to one, two, three, or four SIMD&FP registers.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

## C7.2.155 LD2 (multiple structures)

Load multiple 2-element structures to two registers. This instruction loads multiple 2-element structures from memory and writes the result to the two SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### No offset

### No offset variant

LD2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]

### Decode for this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

### Post-index

### Immediate offset variant

Applies when Rm == 11111.

LD2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>

### Register offset variant

Applies when Rm != 11111.

LD2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>

### Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

### Assembler symbols

- <Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
2D            when size = 11, Q = 1  
The encoding size = 11, Q = 0 is reserved.

<Vt2>        Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<Xn|SP>      Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm>        Is the post-index immediate offset, encoded in the "Q" field. It can have the following values:  
#16           when Q = 0  
#32           when Q = 1

<Xm>        Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

### Shared decode for all encodings

```
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = if Q == '1' then 128 else 64;
integer esize = 8 << UInt(size);
integer elements = datasize DIV esize;

integer rpt;    // number of iterations
integer selem;  // structure elements

case opcode of

    if n == 31 then
        SP[] = address + offs;
    else
        X[n] = address + offs;
```

## C7.2.156 LD2 (single structure)

Load single 2-element structure to one lane of two registers. This instruction loads a 2-element structure from memory and writes the result to the corresponding elements of the two SIMD&FP registers without affecting the other bits of the registers.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

## C7.2.159 LD3 (single structure)

Load single 3-element structure to one lane of three registers). This instruction loads a 3-element structure from memory and writes the result to the corresponding elements of the three SIMD&FP registers without affecting the other bits of the registers.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

## C7.2.161 LD4 (multiple structures)

Load multiple 4-element structures to four registers. This instruction loads multiple 4-element structures from memory and writes the result to the four SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### **Decode for all variants of this encoding**

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

#### **Assembler symbols**

<Vt>	Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
<Vt2>	Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
<Vt3>	Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
<Vt4>	Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.
<index>	For the 8-bit variant: is the element index, encoded in "Q:S:size". For the 16-bit variant: is the element index, encoded in "Q:S:size<1>". For the 32-bit variant: is the element index, encoded in "Q:S". For the 64-bit variant: is the element index, encoded in "Q".
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

## Shared decode for all encodings

```

        X[n] = address + offs;
```

## C7.2.163 LD4R

Load single 4-element structure and Replicate to all lanes of four registers. This instruction loads a 4-element structure from memory and replicates the structure to all the lanes of the four SIMD&FP registers.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### No offset

### No offset variant

LD4R { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]

### Decode for this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

### Post-index

### Immediate offset variant

Applies when Rm == 11111.

LD4R { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>

### Register offset variant

Applies when Rm != 11111.

LD4R { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>

### Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

### Assembler symbols

<Vt>	Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1

2S	when size = 10, Q = 0								
4S	when size = 10, Q = 1								
1D	when size = 11, Q = 0								
2D	when size = 11, Q = 1								
<Vt2>	Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.								
<Vt3>	Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.								
<Vt4>	Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.								
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.								
<imm>	Is the post-index immediate offset, encoded in the "size" field. It can have the following values: <table> <tr> <td>#4</td><td>when size = 00</td></tr> <tr> <td>#8</td><td>when size = 01</td></tr> <tr> <td>#16</td><td>when size = 10</td></tr> <tr> <td>#32</td><td>when size = 11</td></tr> </table>	#4	when size = 00	#8	when size = 01	#16	when size = 10	#32	when size = 11
#4	when size = 00								
#8	when size = 01								
#16	when size = 10								
#32	when size = 11								
<Xm>	Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

```

## C7.2.164 LDNP (SIMD&FP)

Load Pair of SIMD&FP registers, with Non-temporal hint. This instruction loads a pair of SIMD&FP registers from memory, issuing a hint to the memory system that the access is non-temporal. The address that is used for the load is calculated from a base register value and an optional immediate offset.

For information about non-temporal pair instructions, see [Load/Store SIMD and Floating-point Non-temporal pair](#) on page C3-168.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 32-bit variant

Applies when `opc == 00`.

LDNP <St1>, <St2>, [<Xn|SP>{, #<imm>}]

### 64-bit variant

Applies when `opc == 01`.

LDNP <Dt1>, <Dt2>, [<Xn|SP>{, #<imm>}]

### 128-bit variant

Applies when `opc == 10`.

LDNP <Qt1>, <Qt2>, [<Xn|SP>{, #<imm>}]

### Decode for all variants of this encoding

// Empty.

### Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDNP \(SIMD&FP\)](#) on page K1-6125.

### Assembler symbols

<Dt1>	Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
<Dt2>	Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
<Qt1>	Is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
<Qt2>	Is the 128-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
<St1>	Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
<St2>	Is the 32-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

For the 128-bit variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the "imm7" field as <imm>/16.

## Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);
if opc == '11' then UnallocatedEncoding();
integer scale = 2 + UInt(opc);
integer datasize = 8 << scale;
bits(64) offset = LSL(SignExtend(imm7, 64), scale);
```

## Operation

```
CheckFPAdvSIMDEnabled64();

bits(64) address;
bits(datasize) data1;
bits(datasize) data2;
constant integer dbytes = datasize DIV 8;

## C7.2.166 LDR (immediate, SIMD&FP)

Load SIMD&FP Register (immediate offset). This instruction loads an element from memory, and writes the result as a scalar to the SIMD&FP register. The address that is used for the load is calculated from a base register value, a signed immediate offset, and an optional offset that is a multiple of the element size.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  if postindex then
    address = address + offset;
  if n == 31 then
    SP[] = address;
  else
    X[n] = address;
```

### C7.2.167 LDR (literal, SIMD&FP)

Load SIMD&FP Register (PC-relative literal). This instruction loads a SIMD&FP register from memory. The address that is used for the load is calculated from the PC value and an immediate offset.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 32-bit variant

Applies when `opc == 00`.

LDR <St>, <label>

### 64-bit variant

Applies when `opc == 01`.

LDR <Dt>, <label>

### 128-bit variant

Applies when `opc == 10`.

LDR <Qt>, <label>

***Decode for all variants of this encoding***

```

element2 = UInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
    element1 = UInt(Elem[operand1, e, esize]);
    product = (element1*element2)<esize-1:0>;
    if sub_op then
        Elem[result, e, esize] = Elem[operand3, e, esize] - product;
    else
        Elem[result, e, esize] = Elem[operand3, e, esize] + product;
V[d] = result;

```

### C7.2.173 MLS (vector)

Multiply-Subtract from accumulator (vector). This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Three registers of the same type variant

MLS <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean sub_op = (U == '1');
```

#### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

#### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;
```

```
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    product = (UInt(element1)*UInt(element2))<esize-1:0>;
    if sub_op then
        Elem[result, e, esize] = Elem[operand3, e, esize] - product;
    else
        Elem[result, e, esize] = Elem[operand3, e, esize] + product;

V[d] = result;
```

## C7.2.174 MOV (scalar)

Move vector element to scalar. This instruction duplicates the specified vector element in the SIMD&FP source register into a scalar, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the DUP (element) instruction. This means that:

- The encodings in this description are named to match the encodings of DUP (element).
- The description of DUP (element) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	1	0	1	1	1	1	0	0	0	0	0	imm5	0	0	0	0	0	1	Rn	Rd		

### Scalar variant

MOV <V><d>, <Vn>.<T>[<index>]

is equivalent to

DUP <V><d>, <Vn>.<T>[<index>]

and is always the preferred disassembly.

### Assembler symbols

<V> Is the destination width specifier, encoded in the "imm5" field. It can have the following values:

B when imm5 = xxxx1  
H when imm5 = xxx10  
S when imm5 = xx100  
D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is the element width specifier, encoded in the "imm5" field. It can have the following values:

B when imm5 = xxxx1  
H when imm5 = xxx10  
S when imm5 = xx100  
D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<index> Is the element index encoded in the "imm5" field. It can have the following values:

imm5<4:1> when imm5 = xxxx1  
imm5<4:2> when imm5 = xxx10  
imm5<4:3> when imm5 = xx100  
imm5<4> when imm5 = x1000

The encoding imm5 = x0000 is reserved.

## Operation

The description of [DUP \(element\)](#) gives the operational pseudocode for this instruction.

## C7.2.175 MOV (element)

Move vector element to another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the [INS \(element\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [INS \(element\)](#).
- The description of [INS \(element\)](#) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	11	10	9	5	4	0
0	1	1	0	1	1	1	0	0	0	0	0	imm5	0	imm4	1	Rn	Rd			

### Advanced SIMD variant

MOV <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

is equivalent to

INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

and is always the preferred disassembly.

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ts> Is an element size specifier, encoded in the "imm5" field. It can have the following values:

B when imm5 = xxxx1  
H when imm5 = xxx10  
S when imm5 = xx100  
D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<index1> Is the destination element index encoded in the "imm5" field. It can have the following values:

imm5<4:1> when imm5 = xxxx1  
imm5<4:2> when imm5 = xxx10  
imm5<4:3> when imm5 = xx100  
imm5<4> when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index2> Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

imm4<3:0> when imm5 = xxxx1  
imm4<3:1> when imm5 = xxx10  
imm4<3:2> when imm5 = xx100

imm4<3>    when imm5 = x1000

The encoding imm5 = x0000 is reserved.

Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

## Operation

The description of [INS \(element\)](#) gives the operational pseudocode for this instruction.

## C7.2.176 MOV (from general)

Move general-purpose register to a vector element. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the [INS \(general\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [INS \(general\)](#).
- The description of [INS \(general\)](#) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	1	0	0	1	1	1	0	0	0	0	0	imm5	0	0	0	1	1	1	Rn	Rd		

### Advanced SIMD variant

MOV <Vd>.<Ts>[<index>], <R><n>

is equivalent to

INS <Vd>.<Ts>[<index>], <R><n>

and is always the preferred disassembly.

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ts> Is an element size specifier, encoded in the "imm5" field. It can have the following values:

B	when imm5 = xxxx1
H	when imm5 = xxx10
S	when imm5 = xx100
D	when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<index> Is the element index encoded in the "imm5" field. It can have the following values:

imm5<4:1>	when imm5 = xxxx1
imm5<4:2>	when imm5 = xxx10
imm5<4:3>	when imm5 = xx100
imm5<4>	when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<R> Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:

W	when imm5 = xxxx1
W	when imm5 = xxx10
W	when imm5 = xx100
X	when imm5 = x1000

The encoding `imm5 = x0000` is reserved.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

## Operation

The description of [INS \(general\)](#) gives the operational pseudocode for this instruction.

## C7.2.177 MOV (vector)

Move vector. This instruction copies the vector in the source SIMD&FP register into the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the [ORR \(vector, register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ORR \(vector, register\)](#).
- The description of [ORR \(vector, register\)](#) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	0	1	0	1		Rm	0	0	0	1	1	1		Rn		Rd

size

### Three registers of the same type variant

MOV <Vd>.<T>, <Vn>.<T>

is equivalent to

ORR <Vd>.<T>, <Vn>.<T>, <Vn>.<T>

and is the preferred disassembly when Rm == Rn.

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

8B when Q = 0

16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

### Operation

The description of [ORR \(vector, register\)](#) gives the operational pseudocode for this instruction.

## C7.2.178 MOV (to general)

Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the [UMOV](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [UMOV](#).
- The description of [UMOV](#) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when  $Q == 0$  &  $imm5 == xx100$ .

MOV <Wd>, <Vn>.S[<index>]

is equivalent to

UMOV <Wd>, <Vn>.S[<index>]

and is always the preferred disassembly.

### 64-bit variant

Applies when  $Q == 1$  &  $imm5 == x1000$ .

MOV <Xd>, <Vn>.D[<index>]

is equivalent to

UMOV <Xd>, <Vn>.D[<index>]

and is always the preferred disassembly.

## Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index> For the 32-bit variant: is the element index encoded in "imm5<4:3>".  
For the 64-bit variant: is the element index encoded in "imm5<4>".

## Operation

The description of [UMOV](#) gives the operational pseudocode for this instruction.

## C7.2.179 MOV

Move Immediate (vector). This instruction places an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	12	11	10	9	8	7	6	5	4	0
0	Q	op	0	1	1	1	0	0	0	0	0	a	b	c	cmode			0	1	d	e	f	g	h	Rd	

### 8-bit variant

Applies when `op == 0` && `cmode == 1110`.

MOV `<Vd>.<T>`, `#<imm8>{, LSL #0}`

### 16-bit shifted immediate variant

Applies when `op == 0` && `cmode == 10x0`.

MOV `<Vd>.<T>`, `#<imm8>{, LSL #<amount>}`

### 32-bit shifted immediate variant

Applies when `op == 0` && `cmode == 0xx0`.

MOV `<Vd>.<T>`, `#<imm8>{, LSL #<amount>}`

### 32-bit shifting ones variant

Applies when `op == 0` && `cmode == 110x`.

MOV `<Vd>.<T>`, `#<imm8>, MSL #<amount>`

### 64-bit scalar variant

Applies when `Q == 0` && `op == 1` && `cmode == 1110`.

MOV `<Dd>`, `#<imm>`

### 64-bit vector variant

Applies when `Q == 1` && `op == 1` && `cmode == 1110`.

MOV `<Vd>.<2D>`, `#<imm>`

### Decode for all variants of this encoding

```
integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
  when '0xx00' operation = ImmediateOp_MOVI;
  when '0xx01' operation = ImmediateOp_MVNI;
  when '0xx10' operation = ImmediateOp_ORR;
  when '0xx11' operation = ImmediateOp_BIC;
  when '10x00' operation = ImmediateOp_MOVI;
```

```

when '10x01' operation = ImmediateOp_MVNI;
when '10x10' operation = ImmediateOp_ORR;
when '10x11' operation = ImmediateOp_BIC;
when '110x0' operation = ImmediateOp_MOVI;
when '110x1' operation = ImmediateOp_MVNI;
when '1110x' operation = ImmediateOp_MOVI;
when '11110' operation = ImmediateOp_MOVI;
when '11111'
    // FMOV Dn,#imm is in main FP instruction set
    if Q == '0' then UnallocatedEncoding();
    operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);

```

## Assembler symbols

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<imm>	Is a 64-bit immediate 'aaaaaaaabbbbbbccccccddddddeeeeeeffffffffggggggghhhhhhhh', encoded in "a:b:c:d:e:f:g:h".
<T>	For the 8-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values: <div> 8B          when Q = 0 16B        when Q = 1 </div> For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values: <div> 4H          when Q = 0 8H          when Q = 1 </div> For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values: <div> 2S          when Q = 0 4S          when Q = 1 </div>
<imm8>	Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".
<amount>	For the 16-bit shifted immediate variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values: <div> 0            when cmode&lt;1&gt; = 0 8            when cmode&lt;1&gt; = 1 </div> defaulting to 0 if LSL is omitted. For the 32-bit shifted immediate variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values: <div> 0            when cmode&lt;2:1&gt; = 00 8            when cmode&lt;2:1&gt; = 01 16          when cmode&lt;2:1&gt; = 10 24          when cmode&lt;2:1&gt; = 11 </div> defaulting to 0 if LSL is omitted. For the 32-bit shifting ones variant: is the shift amount encoded in the "cmode<0>" field. It can have the following values: <div> 8            when cmode&lt;0&gt; = 0 16          when cmode&lt;0&gt; = 1 </div>

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;
```

## C7.2.180 MUL (by element)

Multiply (vector, by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	1	size	L	M		Rm	1	0	0	0	H	0		Rn			Rd

### Vector variant

MUL <Vd>.<T>, <Vn>.<T>, <Vm>.<Ts>[<index>]

### Decode for this encoding

```
integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

### Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: <div> <div>4H</div> <div>when size = 01, Q = 0</div> <div>8H</div> <div>when size = 01, Q = 1</div> <div>2S</div> <div>when size = 10, Q = 0</div> <div>4S</div> <div>when size = 10, Q = 1</div> </div> The following encodings are reserved: <ul style="list-style-type: none"> <li>size = 00, Q = x.</li> <li>size = 11, Q = x.</li> </ul>
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values: <div> <div>0:Rm</div> <div>when size = 01</div> <div>M:Rm</div> <div>when size = 10</div> </div>

The following encodings are reserved:

- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:

H            when size = 01  
S            when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

H:L:M        when size = 01  
H:L            when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxdsize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) product;

element2 = UInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
    element1 = UInt(Elem[operand1, e, esize]);
    product = (element1*element2)<esize-1:0>;
    Elem[result, e, esize] = product;

V[d] = result;
```

## C7.2.181 MUL (vector)

Multiply (vector). This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

MUL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if U == '1' && size != '00' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean poly = (U == '1');
```

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;

for e = 0 to elements-1
```

```
element1 = Elem[operand1, e, esize];
element2 = Elem[operand2, e, esize];
if poly then
    product = PolynomialMult(element1, element2)<esize-1:0>;
else
    product = (UInt(element1)*UInt(element2))<esize-1:0>;
Elem[result, e, esize] = product;

V[d] = result;
```

## C7.2.182 MVN

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the [NOT](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [NOT](#).
- The description of [NOT](#) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9				5	4				0
0	Q	1	0	1	1	1	0	0	0	1	0	0	0	0	0	0	0	1	0	1	1	0				Rn					Rd

### Vector variant

MVN <Vd>.<T>, <Vn>.<T>

is equivalent to

NOT <Vd>.<T>, <Vn>.<T>

and is always the preferred disassembly.

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

8B when Q = 0

16B when Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation

The description of [NOT](#) gives the operational pseudocode for this instruction.

## C7.2.183 MVNI

Move inverted Immediate (vector). This instruction places the inverse of an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 16-bit shifted immediate variant

Applies when cmode == 10x0.

MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}

### 32-bit shifted immediate variant

Applies when cmode == 0xx0.

MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}

### 32-bit shifting ones variant

Applies when cmode == 110x.

MVNI <Vd>.<T>, #<imm8>, MSL #<amount>

### Decode for all variants of this encoding

```
integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
    when '0xx01' operation = ImmediateOp_MVNI;
    when '0xx11' operation = ImmediateOp_BIC;
    when '10x01' operation = ImmediateOp_MVNI;
    when '10x11' operation = ImmediateOp_BIC;
    when '110x1' operation = ImmediateOp_MVNI;
    when '1110x' operation = ImmediateOp_MOVI;
    when '11111'
        // FMOV Dn,#imm is in main FP instruction set
        if Q == '0' then UnallocatedEncoding();
        operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0

	8H	when Q = 1
	For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:	
	2S	when Q = 0
	4S	when Q = 1
<imm8>	Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".	
<amount>	For the 16-bit shifted immediate variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:	
	0	when cmode<1> = 0
	8	when cmode<1> = 1
	defaulting to 0 if LSL is omitted.	
	For the 32-bit shifted immediate variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:	
	0	when cmode<2:1> = 00
	8	when cmode<2:1> = 01
	16	when cmode<2:1> = 10
	24	when cmode<2:1> = 11
	defaulting to 0 if LSL is omitted.	
	For the 32-bit shifting ones variant: is the shift amount encoded in the "cmode<0>" field. It can have the following values:	
	8	when cmode<0> = 0
	16	when cmode<0> = 1

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;

```

## C7.2.184 NEG (vector)

Negate (vector). This instruction reads each vector element from the source SIMD&FP register, negates each value, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

NEG <V><d>, <V><n>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean neg = (U == '1');
```

### Vector

### Vector variant

NEG <Vd>.<T>, <Vn>.<T>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

### Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.

<d>	Is the number of the SIMD&FP destination register, encoded in the "Rd" field.														
<n>	Is the number of the SIMD&FP source register, encoded in the "Rn" field.														
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.														
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: <table> <tr> <td>8B</td><td>when size = 00, Q = 0</td></tr> <tr> <td>16B</td><td>when size = 00, Q = 1</td></tr> <tr> <td>4H</td><td>when size = 01, Q = 0</td></tr> <tr> <td>8H</td><td>when size = 01, Q = 1</td></tr> <tr> <td>2S</td><td>when size = 10, Q = 0</td></tr> <tr> <td>4S</td><td>when size = 10, Q = 1</td></tr> <tr> <td>2D</td><td>when size = 11, Q = 1</td></tr> </table> The encoding size = 11, Q = 0 is reserved.	8B	when size = 00, Q = 0	16B	when size = 00, Q = 1	4H	when size = 01, Q = 0	8H	when size = 01, Q = 1	2S	when size = 10, Q = 0	4S	when size = 10, Q = 1	2D	when size = 11, Q = 1
8B	when size = 00, Q = 0														
16B	when size = 00, Q = 1														
4H	when size = 01, Q = 0														
8H	when size = 01, Q = 1														
2S	when size = 10, Q = 0														
4S	when size = 10, Q = 1														
2D	when size = 11, Q = 1														
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.														

### Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;

```

## C7.2.185 NOT

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias [MVN](#). The alias is always the preferred disassembly.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	5 4			0
0	Q	1	0	1	1	1	0	0	0	1	0	0	0	0	0	0	1	0	1	1	0	Rn			Rd	

### Vector variant

NOT <Vd>.<T>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
```

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

8B	when Q = 0
16B	when Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = NOT(element);

V[d] = result;
```

## C7.2.186 ORN (vector)

Bitwise inclusive OR NOT (vector). This instruction performs a bitwise OR NOT between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

ORN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
- |     |            |
|-----|------------|
| 8B  | when Q = 0 |
| 16B | when Q = 1 |
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

operand2 = NOT(operand2);

result = operand1 OR operand2;

V[d] = result;
```

## C7.2.187 ORR (vector, immediate)

Bitwise inclusive OR (vector, immediate). This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise OR between each result and an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 16-bit variant

Applies when `cmode == 10x1`.

ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}

### 32-bit variant

Applies when `cmode == 0xx1`.

ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}

### Decode for all variants of this encoding

```
integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
    when '0xx00' operation = ImmediateOp_MOVI;
    when '0xx10' operation = ImmediateOp_ORR;
    when '10x00' operation = ImmediateOp_MOVI;
    when '10x10' operation = ImmediateOp_ORR;
    when '110x0' operation = ImmediateOp_MOVI;
    when '1110x' operation = ImmediateOp_MOVI;
    when '11110' operation = ImmediateOp_MOVI;
imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

### Assembler symbols

<Vd>	Is the name of the SIMD&FP register, encoded in the "Rd" field.
<T>	For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values: <div> <div>4H</div> <div>when Q = 0</div> <div>8H</div> <div>when Q = 1</div> </div> For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values: <div> <div>2S</div> <div>when Q = 0</div> <div>4S</div> <div>when Q = 1</div> </div>
<imm8>	Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount> For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

0	when cmode<1> = 0
8	when cmode<1> = 1

defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

0	when cmode<2:1> = 00
8	when cmode<2:1> = 01
16	when cmode<2:1> = 10
24	when cmode<2:1> = 11

defaulting to 0 if LSL is omitted.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;

```

## C7.2.188 ORR (vector, register)

Bitwise inclusive OR (vector, register). This instruction performs a bitwise OR between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias [MOV \(vector\)](#). See *Alias conditions* for details of when each alias is preferred.

### Three registers of the same type variant

ORR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

### Alias conditions

Alias	is preferred when
<a href="#">MOV (vector)</a>	Rm == Rn

### Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "Q" field. It can have the following values: <div style="margin-left: 20px;"> 8B            when Q = 0  16B          when Q = 1 </div>
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

result = operand1 OR operand2;

V[d] = result;
```

## C7.2.189 PMUL

Polynomial Multiply. This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

For information about multiplying polynomials see [Polynomial arithmetic over {0, 1} on page A1-47](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

PMUL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if U == '1' && size != '00' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean poly = (U == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
- The following encodings are reserved:
- size = 01, Q = x.
  - size = 1x, Q = x.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
```

```
element2 = Elem[operand2, e, esize];  
if poly then  
    product = PolynomialMult(element1, element2)<esize-1:0>;  
else  
    product = (UInt(element1)*UInt(element2))<esize-1:0>;  
Elem[result, e, esize] = product;  
  
V[d] = result;
```

## C7.2.190 PMULL, PMULL2

Polynomial Multiply Long. This instruction multiplies corresponding elements in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see [Polynomial arithmetic over {0, 1}](#) on page A1-47.

The PMULL instruction extracts each source vector from the lower half of each source register, while the PMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	0	size	1	Rm			1	1	1	0	0	0	Rn			Rd

### Three registers, not all the same type variant

PMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '01' || size == '10' then ReservedValue();
if size == '11' && !HaveCryptoExt() then UnallocatedEncoding();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00  
1Q when size = 11
- The following encodings are reserved:
- size = 01.
  - size = 10.
- The '1Q' arrangement is only allocated in an implementation that includes the Cryptographic Extension, and is otherwise RESERVED.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
1D	when size = 11, Q = 0
2D	when size = 11, Q = 1

The following encodings are reserved:

- size = 01, Q = x.
- size = 10, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, 2*esize] = PolynomialMult(element1, element2);

V[d] = result;
```

## C7.2.191 RADDHN, RADDHN2

Rounding Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see [ADDHN](#), [ADDHN2](#).

The RADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31 30 29 28				27 26 25 24				23 22 21 20				16 15 14 13 12 11 10 9								5 4		0	
0	Q	1	0	1	1	1	0	size	1	Rm				0	1	0	0	0	0	Rn		Rd	
U										o1													

### Three registers, not all the same type variant

`RADDHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>`

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1
- The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H	when size = 00
4S	when size = 01
2D	when size = 10

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then

    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;

```

## C7.2.192 RBIT (vector)

Reverse Bit order (vector). This instruction reads each vector element from the source SIMD&FP register, reverses the bits of the element, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9				5	4				0
0	Q	1	0	1	1	1	0	0	1	1	0	0	0	0	0	0	0	1	0	1	1	0				Rn				Rd	

### Vector variant

RBIT <Vd>.<T>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
```

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

8B	when Q = 0
16B	when Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;
bits(esize) rev;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    for i = 0 to esize-1
        rev<esize-1-i> = element<i>;
    Elem[result, e, esize] = rev;

V[d] = result;
```

### C7.2.193 REV16 (vector)

Reverse elements in 16-bit halfwords (vector). This instruction reverses the order of 8-bit elements in each halfword of the vector in the source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Vector variant

REV16 <Vd>.<T>, <Vn>.<T>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

// size=size: B(0), H(1), S(1), D(S)
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;

// op=REVx: 64(0), 32(1), 16(2)
bits(2) op = o0:U;

// => op+size:
// 64+B = 0, 64+H = 1, 64+S = 2, 64+D = X
// 32+B = 1, 32+H = 2, 32+S = X, 32+D = X
// 16+B = 2, 16+H = X, 16+S = X, 16+D = X
// 8+B = X, 8+H = X, 8+S = X, 8+D = X
// => 3-(op+size) (index bits in group)
// 64/B = 3, 64+H = 2, 64+S = 1, 64+D = X
// 32+B = 2, 32+H = 1, 32+S = X, 32+D = X
// 16+B = 1, 16+H = X, 16+S = X, 16+D = X
// 8+B = X, 8+H = X, 8+S = X, 8+D = X

// index bits within group: 1, 2, 3
if UInt(op) + UInt(size) >= 3 then UnallocatedEncoding();

integer container_size;
case op of
    when '10' container_size = 16;
    when '01' container_size = 32;
    when '00' container_size = 64;

integer containers = datasize DIV container_size;
integer elements_per_container = container_size DIV esize;
```

#### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1

The following encodings are reserved:

- size = 01, Q = x.
- size = 1x, Q = x.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element = 0;
integer rev_element;
for c = 0 to containers-1
    rev_element = element + elements_per_container - 1;
    for e = 0 to elements_per_container-1
        Elem[result, rev_element, esize] = Elem[operand, element, esize];
        element = element + 1;
        rev_element = rev_element - 1;

V[d] = result;
```

## C7.2.194 REV32 (vector)

Reverse elements in 32-bit words (vector). This instruction reverses the order of 8-bit or 16-bit elements in each word of the vector in the source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

REV32 <Vd>.<T>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

// size=size:  B(0), H(1), S(1), D(S)
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;

// op=REVx: 64(0), 32(1), 16(2)
bits(2) op = o0:U;

// => op+size:
// 64+B = 0, 64+H = 1, 64+S = 2, 64+D = X
// 32+B = 1, 32+H = 2, 32+S = X, 32+D = X
// 16+B = 2, 16+H = X, 16+S = X, 16+D = X
// 8+B = X, 8+H = X, 8+S = X, 8+D = X
// => 3-(op+size) (index bits in group)
// 64/B = 3, 64+H = 2, 64+S = 1, 64+D = X
// 32+B = 2, 32+H = 1, 32+S = X, 32+D = X
// 16+B = 1, 16+H = X, 16+S = X, 16+D = X
// 8+B = X, 8+H = X, 8+S = X, 8+D = X

// index bits within group: 1, 2, 3
if UInt(op) + UInt(size) >= 3 then UnallocatedEncoding();

integer container_size;
case op of
    when '10' container_size = 16;
    when '01' container_size = 32;
    when '00' container_size = 64;

integer containers = datasize DIV container_size;
integer elements_per_container = container_size DIV esize;
```

### Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0

8H            when size = 01, Q = 1

The encoding size = 1x, Q = x is reserved.

<Vn>            Is the name of the SIMD&FP source register, encoded in the "Rn" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element = 0;
integer rev_element;
for c = 0 to containers-1
    rev_element = element + elements_per_container - 1;

        Elem[result, rev_element, esize] = Elem[operand, element, esize];
        element = element + 1;
        rev_element = rev_element - 1;

V[d] = result;
```

## C7.2.195 REV64

Reverse elements in 64-bit doublewords (vector). This instruction reverses the order of 8-bit, 16-bit, or 32-bit elements in each doubleword of the vector in the source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

REV64 <Vd>.<T>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

// size=size: B(0), H(1), S(1), D(S)
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;

// op=REVx: 64(0), 32(1), 16(2)
bits(2) op = o0:U;

// => op+size:
// 64+B = 0, 64+H = 1, 64+S = 2, 64+D = X
// 32+B = 1, 32+H = 2, 32+S = X, 32+D = X
// 16+B = 2, 16+H = X, 16+S = X, 16+D = X
// 8+B = X, 8+H = X, 8+S = X, 8+D = X
// => 3-(op+size) (index bits in group)
// 64/B = 3, 64+H = 2, 64+S = 1, 64+D = X
// 32+B = 2, 32+H = 1, 32+S = X, 32+D = X
// 16+B = 1, 16+H = X, 16+S = X, 16+D = X
// 8+B = X, 8+H = X, 8+S = X, 8+D = X

// index bits within group: 1, 2, 3
if UInt(op) + UInt(size) >= 3 then UnallocatedEncoding();

integer container_size;
case op of
    when '10' container_size = 16;
    when '01' container_size = 32;
    when '00' container_size = 64;

integer containers = datasize DIV container_size;
integer elements_per_container = container_size DIV esize;
```

### Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0

8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vn>            Is the name of the SIMD&FP source register, encoded in the "Rn" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element = 0;
integer rev_element;
for c = 0 to containers-1
    rev_element = element + elements_per_container - 1;
    for e = 0 to elements_per_container-1
        Elem[result, rev_element, esize] = Elem[operand, element, esize];
        element = element + 1;
        rev_element = rev_element - 1;

V[d] = result;
```

## C7.2.196 RSHRN, RSHRN2

Rounding Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the vector in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see [SHRN](#), [SHRN2](#).

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22		19	18	16	15	14	13	12	11	10	9		5	4		0
0	Q	0	0	1	1	1	1	0		!=0000			immb	1	0	0	0	1	1			Rn			Rd
immh										op															

### Vector variant

RSHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
```

### Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0  
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0  
16B when immh = 0001, Q = 1  
4H when immh = 001x, Q = 0  
8H when immh = 001x, Q = 1  
2S when immh = 01xx, Q = 0  
4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.

	The encoding <code>immh = 1xxx</code> , <code>Q = x</code> is reserved.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<Ta>	Is an arrangement specifier, encoded in the "immh" field. It can have the following values: 8H           when <code>immh = 0001</code> 4S           when <code>immh = 001x</code> 2D           when <code>immh = 01xx</code> See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when <code>immh = 0000</code> . The encoding <code>immh = 1xxx</code> is reserved.
<shift>	Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values: (16-UInt( <code>immh:immb</code> ))   when <code>immh = 0001</code> (32-UInt( <code>immh:immb</code> ))   when <code>immh = 001x</code> (64-UInt( <code>immh:immb</code> ))   when <code>immh = 01xx</code> See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when <code>immh = 0000</code> . The encoding <code>immh = 1xxx</code> is reserved.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;

Vpart[d, part] = result;

```

## C7.2.197 RSUBHN, RSUBHN2

Rounding Subtract returning High Narrow. This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see [SUBHN](#), [SUBHN2](#).

The RSUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

RSUBHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- |           |            |
|-----------|------------|
| [absent]  | when Q = 0 |
| [present] | when Q = 1 |
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00

4S when size = 01

2D when size = 10

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```

## C7.2.198 SABA

Signed Absolute difference and Accumulate. This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the elements of the vector of the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SABA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean accumulate = (ac == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) absdiff;
```

```
result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<esize-1:0>;
    Elem[result, e, esize] = Elem[result, e, esize] + absdiff;
V[d] = result;
```

## C7.2.199 SABAL, SABAL2

Signed Absolute difference and Accumulate Long. This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SABAL instruction extracts each source vector from the lower half of each source register, while the SABAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

SABAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean accumulate = (op == '0');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00  
4S when size = 01  
2D when size = 10  
The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0  
16B when size = 00, Q = 1

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) absdiff;

result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

## C7.2.200 SABD

Signed Absolute Difference. This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, places the absolute values of the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean accumulate = (ac == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) absdiff;
```

```
result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<esize-1:0>;
    Elem[result, e, esize] = Elem[result, e, esize] + absdiff;
V[d] = result;
```

## C7.2.201 SABDL, SABDL2

Signed Absolute Difference Long. This instruction subtracts the vector elements of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, places the absolute value of the results into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SABDL instruction writes the vector to the lower half of the destination register and clears the upper half, while the SABDL2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

SABDL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean accumulate = (op == '0');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
  - 4S when size = 01
  - 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0

16B        when size = 00, Q = 1  
4H        when size = 01, Q = 0  
8H        when size = 01, Q = 1  
2S        when size = 10, Q = 0  
4S        when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>        Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) absdiff;

result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

## C7.2.202 SADALP

Signed Add and Accumulate Long Pairwise. This instruction adds pairs of adjacent signed integer values from the vector in the source SIMD&FP register and accumulates the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

SADALP <Vd>.<Ta>, <Vn>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV (2 * esize);
boolean acc = (op == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |    |                       |
|----|-----------------------|
| 4H | when size = 00, Q = 0 |
| 8H | when size = 00, Q = 1 |
| 2S | when size = 01, Q = 0 |
| 4S | when size = 01, Q = 1 |
| 1D | when size = 10, Q = 0 |
| 2D | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(2*esize) sum;
integer op1;
integer op2;

result = if acc then V[d] else Zeros();
for e = 0 to elements-1
    op1 = Int(Elem[operand, 2*e+0, esize], unsigned);
    op2 = Int(Elem[operand, 2*e+1, esize], unsigned);
    sum = (op1+op2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + sum;

V[d] = result;
```

## C7.2.203 SADDL, SADDL2

Signed Add Long (vector). This instruction adds each vector element in the lower or upper half of the first source SIMD&FP register to the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SADDL instruction extracts each source vector from the lower half of each source register, while the SADDL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

SADDL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- |           |            |
|-----------|------------|
| [absent]  | when Q = 0 |
| [present] | when Q = 1 |
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- |    |                |
|----|----------------|
| 8H | when size = 00 |
| 4S | when size = 01 |
| 2D | when size = 10 |
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

## C7.2.204 SADDLP

Signed Add Long Pairwise. This instruction adds pairs of adjacent signed integer values from the vector in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

SADDLP <Vd>.<Ta>, <Vn>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV (2 * esize);
boolean acc = (op == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |    |                       |
|----|-----------------------|
| 4H | when size = 00, Q = 0 |
| 8H | when size = 00, Q = 1 |
| 2S | when size = 01, Q = 0 |
| 4S | when size = 01, Q = 1 |
| 1D | when size = 10, Q = 0 |
| 2D | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(2*esize) sum;
integer op1;
integer op2;

result = if acc then V[d] else Zeros();
for e = 0 to elements-1
    op1 = Int(Elem[operand, 2*e+0, esize], unsigned);
    op2 = Int(Elem[operand, 2*e+1, esize], unsigned);
    sum = (op1+op2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + sum;

V[d] = result;
```

## C7.2.205 SADDLV

Signed Add Long across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as the source vector elements. All the values in this instruction are signed integer values.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

SADDLV <V><d>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

### Assembler symbols

- <V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
- |   |                |
|---|----------------|
| H | when size = 00 |
| S | when size = 01 |
| D | when size = 10 |
- The encoding size = 11 is reserved.
- <d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 4S  | when size = 10, Q = 1 |
- The following encodings are reserved:
- size = 10, Q = 0.
  - size = 11, Q = x.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer sum;

sum = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    sum = sum + Int(Elem[operand, e, esize], unsigned);

V[d] = sum<2*esize-1:0>;
```

## C7.2.206 SADDW, SADDW2

Signed Add Wide. This instruction adds vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the results in a vector, and writes the vector to the SIMD&FP destination register.

The SADDW instruction extracts the second source vector from the lower half of the second source register, while the SADDW2 instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

SADDW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00  
4S when size = 01  
2D when size = 10  
The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0

16B        when size = 00, Q = 1  
4H        when size = 01, Q = 0  
8H        when size = 01, Q = 1  
2S        when size = 10, Q = 0  
4S        when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

## C7.2.207 SCVTF (vector, fixed-point)

Signed fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the [FPCR](#), and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#), or a synchronous exception being generated. For more information, see [Floating-point exceptions and exception traps on page D1-1831](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

### Scalar

31	30	29	28	27	26	25	24	23	22		19	18	16	15	14	13	12	11	10	9		5	4		0
0	1	0	1	1	1	1	1	0	!	0000			immb	1	1	1	0	0	1			Rn			Rd
U										immh															

### Scalar variant

SCVTF <V><d>, <V><n>, #<fbits>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '000x' || (immh == '001x' && !HaveFP16Ext()) then ReservedValue();
integer esize = if immh == '1xxx' then 64 else if immh == '01xx' then 32 else 16;
integer datasize = esize;
integer elements = 1;

integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);
```

### Vector

31	30	29	28	27	26	25	24	23	22		19	18	16	15	14	13	12	11	10	9		5	4		0
0	Q	0	0	1	1	1	1	0	!	0000			immb	1	1	1	0	0	1			Rn			Rd
U										immh															

### Vector variant

SCVTF <Vd>.<T>, <Vn>.<T>, #<fbits>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh == '000x' || (immh == '001x' && !HaveFP16Ext()) then ReservedValue();
if immh<3>:Q == '10' then ReservedValue();
integer esize = if immh == '1xxx' then 64 else if immh == '01xx' then 32 else 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);
```

## Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
- |   |                  |
|---|------------------|
| H | when immh = 001x |
| S | when immh = 01xx |
| D | when immh = 1xxx |
- The encoding immh = 000x is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- |    |                         |
|----|-------------------------|
| 4H | when immh = 001x, Q = 0 |
| 8H | when immh = 001x, Q = 1 |
| 2S | when immh = 01xx, Q = 0 |
| 4S | when immh = 01xx, Q = 1 |
| 2D | when immh = 1xxx, Q = 1 |
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.
- The following encodings are reserved:
- immh = 0001, Q = x.
  - immh = 1xxx, Q = 0.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:
- |                       |                  |
|-----------------------|------------------|
| (32-UInt(immh:immb))  | when immh = 001x |
| (64-UInt(immh:immb))  | when immh = 01xx |
| (128-UInt(immh:immb)) | when immh = 1xxx |
- The encoding immh = 000x is reserved.
- For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:
- |                       |                  |
|-----------------------|------------------|
| (32-UInt(immh:immb))  | when immh = 001x |
| (64-UInt(immh:immb))  | when immh = 01xx |
| (128-UInt(immh:immb)) | when immh = 1xxx |
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.
- The encoding immh = 0001 is reserved.

## Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
```

```
element = Elem[operand, e, esize];  
Elem[result, e, esize] = FixedToFP(element, fracbits, unsigned, FPCR, rounding);  
V[d] = result;
```

## C7.2.208 SCVTF (vector, integer)

Signed integer Convert to Floating-point (vector). This instruction converts each element in a vector from signed integer to floating-point using the rounding mode that is specified by the [FPCR](#), and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#), or a synchronous exception being generated. For more information, see [Floating-point exceptions and exception traps on page D1-1831](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

```

### Assembler symbols

<Hd>	Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn>	Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<V>	Is a width specifier, encoded in the "sz" field. It can have the following values: <div> <div>S</div> <div>when sz = 0</div> <div>D</div> <div>when sz = 1</div> </div>
<d>	Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<n>	Is the number of the SIMD&FP source register, encoded in the "Rn" field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values: <div> <div>4H</div> <div>when Q = 0</div> </div>

8H            when  $Q = 1$

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S            when  $sz = 0, Q = 0$

4S            when  $sz = 0, Q = 1$

2D            when  $sz = 1, Q = 1$

The encoding  $sz = 1, Q = 0$  is reserved.

<Vn>            Is the name of the SIMD&FP source register, encoded in the "Rn" field.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
FPRounding rounding = FPRoundingMode(FPCR);
bits(esize) element;
for e = 0 to elements-1
    element = E1em[operand, e, esize];
    E1em[result, e, esize] = FixedToFP(element, 0, unsigned, FPCR, rounding);

V[d] = result;

```

## C7.2.209 SCVTF (scalar, fixed-point)

Signed fixed-point Convert to Floating-point (scalar). This instruction converts the signed value in the 32-bit or 64-bit general-purpose source register to a floating-point value using the rounding mode that is specified by the [FPCR](#), and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#), or a synchronous exception being generated. For more information, see [Floating-point exceptions and exception traps on page D1-1831](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

V[d] = result;
```

## C7.2.220 SHA256SU1

SHA256 schedule update 1

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	1	0	1	1	1	1	0	0	0	0		Rm	0	1	1	0	0	0		Rn		Rd

### Advanced SIMD variant

SHA256SU1 <Vd>.4S, <Vn>.4S, <Vm>.4S

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if !HaveCryptoExt() then UnallocatedEncoding();
```

### Assembler symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.

<Vn> Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the third SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckCryptoEnabled64();

bits(128) operand1 = V[d];
bits(128) operand2 = V[n];
bits(128) operand3 = V[m];
bits(128) result;
bits(128) T0 = operand3<31:0>:operand2<127:32>;
bits(64) T1;
bits(32) elt;

T1 = operand3<127:64>;
for e = 0 to 1
    elt = Elem[T1, e, 32];
    elt = ROR(elt, 17) EOR ROR(elt, 19) EOR LSR(elt, 10);
    elt = elt + Elem[operand1, e, 32] + Elem[T0, e, 32];
    Elem[result, e, 32] = elt;

T1 = result<63:0>;
for e = 2 to 3
    elt = Elem[T1, e-2, 32];
    elt = ROR(elt, 17) EOR ROR(elt, 19) EOR LSR(elt, 10);
    elt = elt + Elem[operand1, e, 32] + Elem[T0, e, 32];
    Elem[result, e, 32] = elt;

V[d] = result;
```

## C7.2.221 SHADD

Signed Halving Add. This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see [SRHADD](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    Elem[result, e, esize] = sum<esize:1>;

V[d] = result;
```

## C7.2.222 SHL

Shift Left (immediate). This instruction reads each value from a vector, left shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	1	0	1	1	1	1	1	0	!=0000	immb	0	1	0	1	0	1	Rn			Rd		
immh																						

### Scalar variant

SHL <V><d>, <V><n>, #<shift>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = UInt(immh:immb) - esize;
```

### Vector

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	1	0	!=0000	immb	0	1	0	1	0	1				Rn		Rd
immh																						

### Vector variant

SHL <Vd>.<T>, <Vn>.<T>, #<shift>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
```

### Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:

D when immh = 1xxx

The encoding immh = 0xxx is reserved.

<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values: <div> <div>8B           when immh = 0001, Q = 0</div> <div>16B          when immh = 0001, Q = 1</div> <div>4H           when immh = 001x, Q = 0</div> <div>8H           when immh = 001x, Q = 1</div> <div>2S          when immh = 01xx, Q = 0</div> <div>4S          when immh = 01xx, Q = 1</div> <div>2D          when immh = 1xxx, Q = 1</div> </div> See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when immh = 0000, Q = x. The encoding immh = 1xxx, Q = 0 is reserved.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<shift>	For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values: <div>(UInt(immh:immb)-64)   when immh = 1xxx</div> The encoding immh = 0xxx is reserved. For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values: <div>(UInt(immh:immb)-8)    when immh = 0001</div> <div>(UInt(immh:immb)-16)   when immh = 001x</div> <div>(UInt(immh:immb)-32)   when immh = 01xx</div> <div>(UInt(immh:immb)-64)   when immh = 1xxx</div> See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when immh = 0000.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = LSL(Elem[operand, e, esize], shift);

V[d] = result;

```

## C7.2.223 SHLL, SHLL2

Shift Left Long (by element size). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, left shifts each result by the element size, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SHLL instruction extracts vector elements from the lower half of the source register, while the SHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9				5	4			0
0	Q	1	0	1	1	1	0	size	1	0	0	0	0	1	0	0	1	1	1	0				Rn					Rd	

### Vector variant

SHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = esize;
boolean unsigned = FALSE;    // Or TRUE without change of functionality
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
  - 4S when size = 01
  - 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1

4H            when size = 01, Q = 0

8H            when size = 01, Q = 1

2S            when size = 10, Q = 0

4S            when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<shift>      Is the left shift amount, which must be equal to the source element width in bits, encoded in the "size" field. It can have the following values:

8             when size = 00

16            when size = 01

32            when size = 10

The encoding size = 11 is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

## C7.2.224 SHRN, SHRN2

Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are truncated. For rounded results, see [RSHRN](#), [RSHRN2](#).

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

SHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
```

### Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0  
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0  
16B when immh = 0001, Q = 1  
4H when immh = 001x, Q = 0  
8H when immh = 001x, Q = 1  
2S when immh = 01xx, Q = 0  
4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.

	The encoding <code>immh = 1xxx</code> , <code>Q = x</code> is reserved.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<Ta>	Is an arrangement specifier, encoded in the "immh" field. It can have the following values: 8H           when <code>immh = 0001</code> 4S           when <code>immh = 001x</code> 2D           when <code>immh = 01xx</code> See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when <code>immh = 0000</code> . The encoding <code>immh = 1xxx</code> is reserved.
<shift>	Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values: (16-UInt( <code>immh:immb</code> ))   when <code>immh = 0001</code> (32-UInt( <code>immh:immb</code> ))   when <code>immh = 001x</code> (64-UInt( <code>immh:immb</code> ))   when <code>immh = 01xx</code> See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when <code>immh = 0000</code> . The encoding <code>immh = 1xxx</code> is reserved.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;

Vpart[d, part] = result;

```

## C7.2.225 SHSUB

Signed Halving Subtract. This instruction subtracts the elements in the vector in the second source SIMD&FP register from the corresponding elements in the vector in the first source SIMD&FP register, shifts each result right one bit, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SHSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
```

```
element2 = Int(Elm[operand2, e, esize], unsigned);  
diff = element1 - element2;  
Elm[result, e, esize] = diff<esize:1>;  
  
V[d] = result;
```

## C7.2.226 SLI

Shift Left and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, left shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the left of each vector element in the source register are lost.

The following figure shows the operation of shift left by 3 for an 8-bit vector element.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

SLI <V><d>, <V><n>, #<shift>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = UInt(immh:immb) - esize;
```

### Vector

### Vector variant

SLI <Vd>.<T>, <Vn>.<T>, #<shift>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
```

### Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
- |   |                  |
|---|------------------|
| D | when immh = 1xxx |
|---|------------------|
- The encoding immh = 0xxx is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- |     |                         |
|-----|-------------------------|
| 8B  | when immh = 0001, Q = 0 |

| 4H  | when immh = 001x, Q = 0 |
| 8H  | when immh = 001x, Q = 1 |
| 2S  | when immh = 01xx, Q = 0 |
| 4S  | when immh = 01xx, Q = 1 |
| 2D  | when immh = 1xxx, Q = 1 |
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.
- The encoding immh = 1xxx, Q = 0 is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values:
- |                      |                  |
|----------------------|------------------|
| (UInt(immh:immb)-64) | when immh = 1xxx |
|----------------------|------------------|
- The encoding immh = 0xxx is reserved.
- For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
- |                      |                  |
|----------------------|------------------|
| (UInt(immh:immb)-8)  | when immh = 0001 |
| (UInt(immh:immb)-16) | when immh = 001x |
| (UInt(immh:immb)-32) | when immh = 01xx |
| (UInt(immh:immb)-64) | when immh = 1xxx |
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

### Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2 = V[d];
bits(datasize) result;
```

```
bits(size) mask = LSL(Ones(size), shift);
bits(size) shifted;

for e = 0 to elements-1
    shifted = LSL(Elm[operand, e, size], shift);
    Elm[result, e, size] = (Elm[operand2, e, size] AND NOT(mask)) OR shifted;
V[d] = result;
```

## C7.2.227 SMAX

Signed Maximum (vector). This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the larger of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SMAX <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer maxmin;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
    Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
```

## C7.2.228 SMAXP

Signed Maximum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SMAXP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
integer element1;
integer element2;
```

```
integer maxmin;  
  
for e = 0 to elements-1  
    element1 = Int(Elem[concat, 2*e, esize], unsigned);  
    element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);  
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);  
    Elem[result, e, esize] = maxmin<esize-1:0>;  
  
V[d] = result;
```

## C7.2.229 SMAXV

Signed Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are signed integer values.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

SMAXV <V><d>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');
```

### Assembler symbols

- <V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
- |   |                |
|---|----------------|
| B | when size = 00 |
| H | when size = 01 |
| S | when size = 10 |
- The encoding size = 11 is reserved.
- <d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 4S  | when size = 10, Q = 1 |
- The following encodings are reserved:
- size = 10, Q = 0.
  - size = 11, Q = x.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin<esize-1:0>;
```

## C7.2.230 SMIN

Signed Minimum (vector). This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the smaller of each of the two signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SMIN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer maxmin;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
    Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
```

## C7.2.231 SMINP

Signed Minimum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SMINP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
integer element1;
integer element2;
```

```
integer maxmin;  
  
for e = 0 to elements-1  
    element1 = Int(Elem[concat, 2*e, esize], unsigned);  
    element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);  
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);  
    Elem[result, e, esize] = maxmin<esize-1:0>;  
  
V[d] = result;
```

## C7.2.232 SMINV

Signed Minimum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are signed integer values.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

SMINV <V><d>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');
```

### Assembler symbols

- <V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
- |   |                |
|---|----------------|
| B | when size = 00 |
| H | when size = 01 |
| S | when size = 10 |
- The encoding size = 11 is reserved.
- <d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 4S  | when size = 10, Q = 1 |
- The following encodings are reserved:
- size = 10, Q = 0.
  - size = 11, Q = x.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin<esize-1:0>;
```

### C7.2.233 SMLAL, SMLAL2 (by element)

Signed Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

The SMLAL instruction extracts vector elements from the lower half of the first source register, while the SMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Vector variant

SMLAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

#### Decode for this encoding

```

integer idxsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
```

#### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
- [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 4S when size = 01
- 2D when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

- 0:Rm when size = 01
- M:Rm when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

- H:L:M when size = 01
- H:L when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsizesize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
```

```
if sub_op then
    Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
else
    Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] + product;
V[d] = result;
```

## C7.2.234 SMLAL, SMLAL2 (vector)

Signed Multiply-Add Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLAL instruction extracts each source vector from the lower half of each source register, while the SMLAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

SMLAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
  - 4S when size = 01
  - 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;

V[d] = result;
```

## C7.2.235 SMLSL, SMLSL2 (by element)

Signed Multiply-Subtract Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLSL instruction extracts vector elements from the lower half of the first source register, while the SMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

SMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

### Decode for this encoding

```

integer idxsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
    
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 4S when size = 01
  - 2D when size = 10
- The following encodings are reserved:
- size = 00.

- size = 11.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 4H            when size = 01, Q = 0
- 8H            when size = 01, Q = 1
- 2S            when size = 10, Q = 0
- 4S            when size = 10, Q = 1
- The following encodings are reserved:
- size = 00, Q = x.
  - size = 11, Q = x.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- 0:Rm          when size = 01
- M:Rm          when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.
- Restricted to V0-V15 when element size <Ts> is H.
- <Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
- H            when size = 01
- S            when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.
- <index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- H:L:M        when size = 01
- H:L          when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else

```

```
Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] + product;  
V[d] = result;
```

## C7.2.236 SMLSL, SMLSL2 (vector)

Signed Multiply-Subtract Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLSL instruction extracts each source vector from the lower half of each source register, while the SMLSL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

SMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- |           |            |
|-----------|------------|
| [absent]  | when Q = 0 |
| [present] | when Q = 1 |
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- |    |                |
|----|----------------|
| 8H | when size = 00 |
| 4S | when size = 01 |
| 2D | when size = 10 |
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;

V[d] = result;
```

## C7.2.237 SMOV

Signed Move vector element to general-purpose register. This instruction reads the signed integer from the source SIMD&FP register, sign-extends it to form a 32-bit or 64-bit value, and writes the result to destination general-purpose register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	0	0	0	0	0	imm5	0	0	1	0	1	1	Rn	Rd		

### 32-bit variant

Applies when Q == 0.

SMOV <Wd>, <Vn>.<Ts>[<index>]

### 64-bit variant

Applies when Q == 1.

SMOV <Xd>, <Vn>.<Ts>[<index>]

### Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size;
case Q:imm5 of
  when 'xxxxx1' size = 0; // SMOV [WX]d, Vn.B
  when 'xxxx10' size = 1; // SMOV [WX]d, Vn.H
  when '1xx100' size = 2; // SMOV Xd, Vn.S
  otherwise UnallocatedEncoding();

integer idxsize = if imm5<4> == '1' then 128 else 64;
integer index = UInt(imm5<4:size+1>);
integer esize = 8 << size;
integer datasize = if Q == '1' then 64 else 32;
```

### Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<Ts>	For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values: B           when imm5 = xxxx1 H           when imm5 = xxx10 The encoding imm5 = xxx00 is reserved. For the 64-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values: B           when imm5 = xxxx1

H            when imm5 = xxx10  
S            when imm5 = xx100  
The encoding imm5 = xx000 is reserved.

<index>      For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:

imm5<4:1>   when imm5 = xxxx1  
imm5<4:2>   when imm5 = xxx10  
The encoding imm5 = xxx00 is reserved.

For the 64-bit variant: is the element index encoded in the "imm5" field. It can have the following values:

imm5<4:1>   when imm5 = xxxx1  
imm5<4:2>   when imm5 = xxx10  
imm5<4:3>   when imm5 = xx100  
The encoding imm5 = xx000 is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];

X[d] = SignExtend(Elem[operand, index, esize], datasize);
```

## C7.2.238 SMULL, SMULL2 (by element)

Signed Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMULL instruction extracts vector elements from the lower half of the first source register, while the SMULL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

SMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

### Decode for this encoding

```

integer idxsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 4S when size = 01  
2D when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.

<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.								
<Tb>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: <table> <tr> <td>4H</td><td>when size = 01, Q = 0</td></tr> <tr> <td>8H</td><td>when size = 01, Q = 1</td></tr> <tr> <td>2S</td><td>when size = 10, Q = 0</td></tr> <tr> <td>4S</td><td>when size = 10, Q = 1</td></tr> </table> The following encodings are reserved: <ul style="list-style-type: none"> <li>size = 00, Q = x.</li> <li>size = 11, Q = x.</li> </ul>	4H	when size = 01, Q = 0	8H	when size = 01, Q = 1	2S	when size = 10, Q = 0	4S	when size = 10, Q = 1

2S	when size = 10, Q = 0								
4S	when size = 10, Q = 1								
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values: <table> <tr> <td>0:Rm</td><td>when size = 01</td></tr> <tr> <td>M:Rm</td><td>when size = 10</td></tr> </table> The following encodings are reserved: <ul style="list-style-type: none"> <li>size = 00.</li> <li>size = 11.</li> </ul> Restricted to V0-V15 when element size <Ts> is H.	0:Rm	when size = 01	M:Rm	when size = 10				
0:Rm	when size = 01								
M:Rm	when size = 10								
<Ts>	Is an element size specifier, encoded in the "size" field. It can have the following values: <table> <tr> <td>H</td><td>when size = 01</td></tr> <tr> <td>S</td><td>when size = 10</td></tr> </table> The following encodings are reserved: <ul style="list-style-type: none"> <li>size = 00.</li> <li>size = 11.</li> </ul>	H	when size = 01	S	when size = 10				
H	when size = 01								
S	when size = 10								
<index>	Is the element index, encoded in the "size:L:H:M" field. It can have the following values: <table> <tr> <td>H:L:M</td><td>when size = 01</td></tr> <tr> <td>H:L</td><td>when size = 10</td></tr> </table> The following encodings are reserved: <ul style="list-style-type: none"> <li>size = 00.</li> <li>size = 11.</li> </ul>	H:L:M	when size = 01	H:L	when size = 10				
H:L:M	when size = 01								
H:L	when size = 10								

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsizesize) operand2 = V[m];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = product;

V[d] = result;

```

## C7.2.239 SMULL, SMULL2 (vector)

Signed Multiply Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

The destination vector elements are twice as long as the elements that are multiplied.

The SMULL instruction extracts each source vector from the lower half of each source register, while the SMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

SMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
- [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
- 4S when size = 01
- 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, 2*esize] = (element1*element2)<2*esize-1:0>;

V[d] = result;
```

## C7.2.240 SQABS

Signed saturating Absolute value. This instruction reads each vector element from the source SIMD&FP register, puts the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

SQABS <V><d>, <V><n>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean neg = (U == '1');
```

### Vector

### Vector variant

SQABS <Vd>.<T>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

### Assembler symbols

<V>            Is a width specifier, encoded in the "size" field. It can have the following values:

B	when size = 00
H	when size = 01
S	when size = 10

D	when size = 11														
<d>	Is the number of the SIMD&FP destination register, encoded in the "Rd" field.														
<n>	Is the number of the SIMD&FP source register, encoded in the "Rn" field.														
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.														
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: <table> <tr> <td>8B</td><td>when size = 00, Q = 0</td></tr> <tr> <td>16B</td><td>when size = 00, Q = 1</td></tr> <tr> <td>4H</td><td>when size = 01, Q = 0</td></tr> <tr> <td>8H</td><td>when size = 01, Q = 1</td></tr> <tr> <td>2S</td><td>when size = 10, Q = 0</td></tr> <tr> <td>4S</td><td>when size = 10, Q = 1</td></tr> <tr> <td>2D</td><td>when size = 11, Q = 1</td></tr> </table> The encoding size = 11, Q = 0 is reserved.	8B	when size = 00, Q = 0	16B	when size = 00, Q = 1	4H	when size = 01, Q = 0	8H	when size = 01, Q = 1	2S	when size = 10, Q = 0	4S	when size = 10, Q = 1	2D	when size = 11, Q = 1
8B	when size = 00, Q = 0														
16B	when size = 00, Q = 1														
4H	when size = 01, Q = 0														
8H	when size = 01, Q = 1														
2S	when size = 10, Q = 0														
4S	when size = 10, Q = 1														
2D	when size = 11, Q = 1														
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.														

### Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    (Elem[result, e, esize], sat) = SignedSatQ(element, esize);
    if sat then FPSR.QC = '1';

V[d] = result;

```

## C7.2.241 SQADD

Signed saturating Add. This instruction adds the values of corresponding elements of the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

SQADD <V><d>, <V><n>, <V><m>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
```

### Vector

### Vector variant

SQADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

### Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

B	when size = 00
H	when size = 01
S	when size = 10

	D	when size = 11
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.	
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.	
<m>	Is the number of the second SIMD&FP source register, encoded in the "Rm" field.	
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.	
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:	
	8B	when size = 00, Q = 0
	16B	when size = 00, Q = 1
	4H	when size = 01, Q = 0
	8H	when size = 01, Q = 1
	2S	when size = 10, Q = 0
	4S	when size = 10, Q = 1
	2D	when size = 11, Q = 1
	The encoding size = 11, Q = 0 is reserved.	
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.	
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.	

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
boolean sat;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    (Elem[result, e, esize], sat) = SatQ(sum, esize, unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;

```

## C7.2.242 SQDMLAL, SQDMLAL2 (by element)

Signed saturating Doubling Multiply-Add Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The SQDMLAL instruction extracts vector elements from the lower half of the first source register, while the SQDMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    else

```

```
    accum = SInt(Elem[operand3, e, 2*esize]) + SInt(product);  
    (Elem[result, e, 2*esize], sat2) = SignedSatQ(accum, 2 * esize);  
    if sat1 || sat2 then FPSR.QC = '1';  
  
V[d] = result;
```

## C7.2.243 SQDMLAL, SQDMLAL2 (vector)

Signed saturating Doubling Multiply-Add Long. This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The SQDMLAL instruction extracts each source vector from the lower half of each source register, while the SQDMLAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

## C7.2.244 SQDMLSL, SQDMLSL2 (by element)

Signed saturating Doubling Multiply-Subtract Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and subtracts the final results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The SQDMLSL instruction extracts vector elements from the lower half of the first source register, while the SQDMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    product = (2 * element1 * element2) + round_const;
    (Elem[result, e, esize], sat) = SignedSatQ(product >> esize, esize);
    if sat then FPSR.QC = '1';

V[d] = result;

```

## C7.2.248 SQDMULL, SQDMULL2 (by element)

Signed saturating Doubling Multiply Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The SQDMULL instruction extracts the first source vector from the lower half of the first source register, while the SQDMULL2 instruction extracts the first source vector from the upper half of the first source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';

V[d] = result;
```

### C7.2.253 SQRDMLSH (by element)

Signed Saturating Rounding Doubling Multiply Subtract returning High Half (by element). This instruction multiplies the vector elements of the first source SIMD&FP register with the value of a vector element of the second source SIMD&FP register without saturating the multiply results, doubles the results, and subtracts the most significant half of the final results from the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSR.QC](#), is set if saturation occurs.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1
2D	when size = 11, Q = 1
	The encoding size = 11, Q = 0 is reserved.
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1);    // 0 for left shift, 2^(n-1) for right shift
    element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;

```

## C7.2.258 SQRSHRN, SQRSHRN2

Signed saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see [SQSHRN](#), [SQSHRN2](#).

The SQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
```

```
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
boolean unsigned = (U == '1');
```

## Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- 8B when immh = 0001, Q = 0  
16B when immh = 0001, Q = 1  
4H when immh = 001x, Q = 0  
8H when immh = 001x, Q = 1  
2S when immh = 01xx, Q = 0  
4S when immh = 01xx, Q = 1
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.  
The encoding immh = 1xxx, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
- 8H when immh = 0001  
4S when immh = 001x  
2D when immh = 01xx
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.  
The encoding immh = 1xxx is reserved.
- <Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:
- B when immh = 0001  
H when immh = 001x  
S when immh = 01xx
- The following encodings are reserved:
- immh = 0000.
  - immh = 1xxx.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:
- H when immh = 0001  
S when immh = 001x  
D when immh = 01xx

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See [Advanced SIMD modified immediate on page C4-291](#) when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;

```

## C7.2.259 SQRSHRUN, SQRSHRUN2

Signed saturating Rounded Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are rounded. For truncated results, see [SQSHRUN](#), [SQSHRUN2](#).

The SQRSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], src_unsigned) << shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```

## C7.2.261 SQSHL (register)

Signed saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see [SQRSHL](#).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

        round_const = 1 << (-shift - 1);    // 0 for left shift, 2^(n-1) for right shift
    element = (Int(Elm[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elm[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elm[result, e, esize] = element<esize-1:0>;

V[d] = result;

```

## C7.2.262 SQSHLU

Signed saturating Shift Left Unsigned (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, shifts each value by an immediate value, saturates the shifted result to an unsigned integer value, places the result in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see [UQRSHL](#).

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

| (UInt(immh:immb)-64) | when immh = 1xxx |

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

## Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], src_unsigned) << shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```

## C7.2.263 SQSHRN, SQSHRN2

Signed saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see [SQRSHRN](#), [SQRSHRN2](#).

The SQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
boolean unsigned = (U == '1');
```

## Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- 8B when immh = 0001, Q = 0  
16B when immh = 0001, Q = 1  
4H when immh = 001x, Q = 0  
8H when immh = 001x, Q = 1  
2S when immh = 01xx, Q = 0  
4S when immh = 01xx, Q = 1
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.  
The encoding immh = 1xxx, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
- 8H when immh = 0001  
4S when immh = 001x  
2D when immh = 01xx
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.  
The encoding immh = 1xxx is reserved.
- <Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:
- B when immh = 0001  
H when immh = 001x  
S when immh = 01xx
- The following encodings are reserved:
- immh = 0000.
  - immh = 1xxx.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:
- H when immh = 0001  
S when immh = 001x  
D when immh = 01xx

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See [Advanced SIMD modified immediate on page C4-291](#) when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

## Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

## C7.2.264 SQSHRUN, SQSHRUN2

Signed saturating Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see [SQRSHRUN](#), [SQRSHRUN2](#).

The SQSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
```

### Vector

### Vector variant

SQSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

### Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

B	when size = 00
H	when size = 01
S	when size = 10

	D	when size = 11
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.	
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.	
<m>	Is the number of the second SIMD&FP source register, encoded in the "Rm" field.	
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.	
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:	
	8B	when size = 00, Q = 0
	16B	when size = 00, Q = 1
	4H	when size = 01, Q = 0
	8H	when size = 01, Q = 1
	2S	when size = 10, Q = 0
	4S	when size = 10, Q = 1
	2D	when size = 11, Q = 1
	The encoding size = 11, Q = 0 is reserved.	
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.	
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.	

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;
boolean sat;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    diff = element1 - element2;
    (Elem[result, e, esize], sat) = SatQ(diff, esize, unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;

```

## C7.2.266 SQXTN, SQXTN2

Signed saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates the value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The SQXTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQXTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer part = UInt(Q);
```

integer elements = datasize DIV esize;

boolean unsigned = (U == '1');

## Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00

4S when size = 01

2D when size = 10

The encoding size = 11 is reserved.

<Vb> Is the destination width specifier, encoded in the "size" field. It can have the following values:

B when size = 00

H when size = 01

S when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Va> Is the source width specifier, encoded in the "size" field. It can have the following values:

H when size = 00

S when size = 01

D when size = 10

The encoding size = 11 is reserved.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

## Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;
boolean sat;
```

```
for e = 0 to elements-1
    element = Elem[operand, e, 2*esize];
    (Elem[result, e, esize], sat) = SatQ(Int(element, unsigned), esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

## C7.2.267 SQXTUN, SQXTUN2

Signed saturating extract Unsigned Narrow. This instruction reads each signed integer value in the vector of the source SIMD&FP register, saturates the value to an unsigned integer value that is half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The SQXTUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQXTUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9			5	4		0

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;
boolean sat;

for e = 0 to elements-1
    element = E1em[operand, e, 2*esize];
    (E1em[result, e, esize], sat) = UnsignedSatQ(SInt(element), esize);

```

```
if sat then FPSR.QC = '1';  
Vpart[d, part] = result;
```

## C7.2.268 SRHADD

Signed Rounding Halving Add. This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see [SHADD](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SRHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, esize] = (element1+element2+1)<esize:1>;

V[d] = result;
```

## C7.2.269 SRI

Shift Right and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the right of each vector element of the source register are lost.

The following figure shows the operation of shift right by 3 for an 8-bit vector element.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

31	30	29	28	27	26	25	24	23	22		19	18	16	15	14	13	12	11	10	9		5	4		0
0	1	1	1	1	1	1	1	0		!=0000		immb		0	1	0	0	0	1		Rn				Rd
										immh															

### Scalar variant

| (64-UInt(immh:immb))  | when immh = 01xx |
| (128-UInt(immh:immb)) | when immh = 1xxx |
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

### Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2 = V[d];
bits(datasize) result;
```

```
bits(size) mask = LSR(Ones(size), shift);
bits(size) shifted;

for e = 0 to elements-1
    shifted = LSR(Elm[operand, e, size], shift);
    Elm[result, e, size] = (Elm[operand2, e, size] AND NOT(mask)) OR shifted;
V[d] = result;
```

## C7.2.270 SRSHL

Signed Rounding Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see [SSHL](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

SRSHL <V><d>, <V><n>, <V><m>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

boolean accumulate = (o0 == '1');
```

## Assembler symbols

<V>	Is a width specifier, encoded in the "immh" field. It can have the following values: D           when immh = 1xxx The encoding immh = 0xxx is reserved.
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values: 8B           when immh = 0001, Q = 0 16B          when immh = 0001, Q = 1 4H           when immh = 001x, Q = 0 8H           when immh = 001x, Q = 1 2S           when immh = 01xx, Q = 0 4S           when immh = 01xx, Q = 1 2D           when immh = 1xxx, Q = 1 See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when immh = 0000, Q = x. The encoding immh = 1xxx, Q = 0 is reserved.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<shift>	For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values: (128-UInt(immh:immb)) when immh = 1xxx The encoding immh = 0xxx is reserved. For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values: (16-UInt(immh:immb))   when immh = 0001 (32-UInt(immh:immb))   when immh = 001x (64-UInt(immh:immb))   when immh = 01xx (128-UInt(immh:immb))  when immh = 1xxx See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when immh = 0000.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;

```

## C7.2.273 SSHL

Signed Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts each value by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see [SRSHL](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

SSHL <V><d>, <V><n>, <V><m>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
if S == '0' && size != '11' then ReservedValue();
```

### Vector

### Vector variant

SSHL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
```

## Assembler symbols

<V>	Is a width specifier, encoded in the "size" field. It can have the following values: D            when size = 11 The following encodings are reserved: <ul style="list-style-type: none"> <li>size = 0x.</li> <li>size = 10.</li> </ul>
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<m>	Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: 8B            when size = 00, Q = 0 16B          when size = 00, Q = 1 4H            when size = 01, Q = 0 8H            when size = 01, Q = 1 2S            when size = 10, Q = 0 4S            when size = 10, Q = 1 2D            when size = 11, Q = 1 The encoding size = 11, Q = 0 is reserved.
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elm[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1);    // 0 for left shift, 2^(n-1) for right shift
    element = (Int(Elm[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elm[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elm[result, e, esize] = element<esize-1:0>;

V[d] = result;

```

## C7.2.274 SSHLL, SSHLL2

Signed Shift Left Long (immediate). This instruction reads each vector element from the source SIMD&FP register, left shifts each vector element by the specified shift amount, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SSHLL instruction extracts vector elements from the lower half of the source register, while the SSHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias SXTL, SXTL2. See *Alias conditions* for details of when each alias is preferred.

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	1	0	!	=0000	immb	1	0	1	0	0	1	Rn			Rd	
U										immh												

### Vector variant

SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
boolean unsigned = (U == '1');
```

### Alias conditions

Alias	is preferred when
SXTL, SXTL2	immb == '000' && BitCount(immh) == 1

### Assembler symbols

2	Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values: [absent] when Q = 0 [present] when Q = 1
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta>	Is an arrangement specifier, encoded in the "immh" field. It can have the following values: 8H when immh = 0001 4S when immh = 001x

2D            when immh = 01xx

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn>            Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb>            Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B            when immh = 0001, Q = 0

16B           when immh = 0001, Q = 1

4H            when immh = 001x, Q = 0

8H            when immh = 001x, Q = 1

2S            when immh = 01xx, Q = 0

4S            when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<shift>            Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

(UInt(immh:immb)-8)    when immh = 0001

(UInt(immh:immb)-16)    when immh = 001x

(UInt(immh:immb)-32)    when immh = 01xx

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

## C7.2.275 SSHR

Signed Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, places the final result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are truncated. For rounded results, see [SRSHR](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

V[d] = result;

```

## C7.2.277 SSUBL, SSUBL2

Signed Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are twice as long as the source vector elements.

The SSUBL instruction extracts each source vector from the lower half of each source register, while the SSUBL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

SSUBL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- |           |            |
|-----------|------------|
| [absent]  | when Q = 0 |
| [present] | when Q = 1 |
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- |    |                |
|----|----------------|
| 8H | when size = 00 |
| 4S | when size = 01 |
| 2D | when size = 10 |
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

## C7.2.278 SSUBW, SSUBW2

Signed Subtract Wide. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. All the values in this instruction are signed integer values.

The SSUBW instruction extracts the second source vector from the lower half of the second source register, while the SSUBW2 instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

SSUBW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

### Decode for this encoding

```

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
- [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
- 4S when size = 01
- 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;

```

## C7.2.279 ST1 (multiple structures)

Store multiple single-element structures from one, two, three, or four registers. This instruction stores elements to memory from one, two, three, or four SIMD&FP registers, without interleaving. Every element of each register is stored.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 8-bit, immediate offset variant

Applies when Rm == 11111 && opcode == 001.

ST4 { <Vt>.B, <Vt2>.B, <Vt3>.B, <Vt4>.B }[<index>], [<Xn|SP>], #4

### 8-bit, register offset variant

Applies when Rm != 11111 && opcode == 001.

ST4 { <Vt>.B, <Vt2>.B, <Vt3>.B, <Vt4>.B }[<index>], [<Xn|SP>], <Xm>

### 16-bit, immediate offset variant

Applies when  $Rm == 11111$  && opcode == 011 && size == x0.

ST4 { <Vt>.H, <Vt2>.H, <Vt3>.H, <Vt4>.H }[<index>], [<Xn|SP>], #8

### 16-bit, register offset variant

Applies when  $Rm != 11111$  && opcode == 011 && size == x0.

ST4 { <Vt>.H, <Vt2>.H, <Vt3>.H, <Vt4>.H }[<index>], [<Xn|SP>], <Xm>

### 32-bit, immediate offset variant

Applies when  $Rm == 11111$  && opcode == 101 && size == 00.

ST4 { <Vt>.S, <Vt2>.S, <Vt3>.S, <Vt4>.S }[<index>], [<Xn|SP>], #16

### 32-bit, register offset variant

Applies when  $Rm != 11111$  && opcode == 101 && size == 00.

ST4 { <Vt>.S, <Vt2>.S, <Vt3>.S, <Vt4>.S }[<index>], [<Xn|SP>], <Xm>

### 64-bit, immediate offset variant

Applies when  $Rm == 11111$  && opcode == 101 && S == 0 && size == 01.

ST4 { <Vt>.D, <Vt2>.D, <Vt3>.D, <Vt4>.D }[<index>], [<Xn|SP>], #32

### 64-bit, register offset variant

Applies when  $Rm != 11111$  && opcode == 101 && S == 0 && size == 01.

ST4 { <Vt>.D, <Vt2>.D, <Vt3>.D, <Vt4>.D }[<index>], [<Xn|SP>], <Xm>

### Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

### Assembler symbols

<Vt>	Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
<Vt2>	Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
<Vt3>	Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
<Vt4>	Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.
<index>	For the 8-bit variant: is the element index, encoded in "Q:S:size". For the 16-bit variant: is the element index, encoded in "Q:S:size<1>". For the 32-bit variant: is the element index, encoded in "Q:S". For the 64-bit variant: is the element index, encoded in "Q".
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

## Shared decode for all encodings

```
integer scale = UInt(opcode<2:1>);

```

## C7.2.287 STNP (SIMD&FP)

Store Pair of SIMD&FP registers, with Non-temporal hint. This instruction stores a pair of SIMD&FP registers to memory, issuing a hint to the memory system that the access is non-temporal. The address used for the store is calculated from an address from a base register value and an immediate offset. For information about non-temporal pair instructions, see [Load/Store SIMD and Floating-point Non-temporal pair](#) on page C3-168.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 32-bit variant

Applies when `opc == 00`.

STNP <St1>, <St2>, [<Xn|SP>{, #<imm>}]

### 64-bit variant

Applies when `opc == 01`.

STNP <Dt1>, <Dt2>, [<Xn|SP>{, #<imm>}]

### 128-bit variant

Applies when `opc == 10`.

STNP <Qt1>, <Qt2>, [<Xn|SP>{, #<imm>}]

### Decode for all variants of this encoding

// Empty.

### Assembler symbols

- <Dt1> Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
- <Dt2> Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
- <Qt1> Is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
- <Qt2> Is the 128-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
- <St1> Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
- <St2> Is the 32-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <imm> For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.  
For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.  
For the 128-bit variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the "imm7" field as <imm>/16.

## Shared decode for all encodings

    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```

## C7.2.291 STUR (SIMD&FP)

Store SIMD&FP register (unscaled offset). This instruction stores a single SIMD&FP register to memory. The address that is used for the store is calculated from a base register value and an optional immediate offset.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31 30 29 28				27 26 25 24				23 22 21 20								12				11 10 9								5 4		0		
size				1	1	1	1	0	0	x	0	0	imm9								0		0		Rn				Rt			
opc																																

### 8-bit variant

Applies when size == 00 && opc == 00.

STUR <Bt>, [<Xn|SP>{, #<sim>}]

### 16-bit variant

Applies when size == 01 && opc == 00.

STUR <Ht>, [<Xn|SP>{, #<sim>}]

### 32-bit variant

Applies when size == 10 && opc == 00.

STUR <St>, [<Xn|SP>{, #<sim>}]

### 64-bit variant

Applies when size == 11 && opc == 00.

STUR <Dt>, [<Xn|SP>{, #<sim>}]

### 128-bit variant

Applies when size == 00 && opc == 10.

STUR <Qt>, [<Xn|SP>{, #<sim>}]

### Decode for all variants of this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(opc<1>:size);
if scale > 4 then UnallocatedEncoding();
bits(64) offset = SignExtend(imm9, 64);
```

### Assembler symbols

<Bt>	Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
<Dt>	Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
<Ht>	Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
<Qt>	Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
<St>	Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

## Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_VEC;
MemOp memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = 8 << scale;
```

## Operation

```
CheckFPAdvSIMDEnabled64();

bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();

    else
        X[n] = address;
```

## C7.2.292 SUB (vector)

Subtract (vector). This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

SUB <V><d>, <V><n>, <V><m>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean sub_op = (U == '1');
```

### Vector

### Vector variant

SUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (U == '1');
```

### Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.

<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.														
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.														
<m>	Is the number of the second SIMD&FP source register, encoded in the "Rm" field.														
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.														
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: <table> <tr> <td>8B</td><td>when size = 00, Q = 0</td></tr> <tr> <td>16B</td><td>when size = 00, Q = 1</td></tr> <tr> <td>4H</td><td>when size = 01, Q = 0</td></tr> <tr> <td>8H</td><td>when size = 01, Q = 1</td></tr> <tr> <td>2S</td><td>when size = 10, Q = 0</td></tr> <tr> <td>4S</td><td>when size = 10, Q = 1</td></tr> <tr> <td>2D</td><td>when size = 11, Q = 1</td></tr> </table> The encoding size = 11, Q = 0 is reserved.	8B	when size = 00, Q = 0	16B	when size = 00, Q = 1	4H	when size = 01, Q = 0	8H	when size = 01, Q = 1	2S	when size = 10, Q = 0	4S	when size = 10, Q = 1	2D	when size = 11, Q = 1
8B	when size = 00, Q = 0														
16B	when size = 00, Q = 1														
4H	when size = 01, Q = 0														
8H	when size = 01, Q = 1														
2S	when size = 10, Q = 0														
4S	when size = 10, Q = 1														
2D	when size = 11, Q = 1														
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.														
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.														

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;

V[d] = result;

```

## C7.2.293 SUBHN, SUBHN2

Subtract returning High Narrow. This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values.

The results are truncated. For rounded results, see [RSUBHN](#), [RSUBHN2](#).

The SUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31 30 29 28   27 26 25 24   23 22 21 20								16   15 14 13 12   11 10 9								5 4		0					
0	Q	0	0	1	1	1	0	size	1	Rm			0	1	1	0	0	0	Rn			Rd	
U										o1													

### Three registers, not all the same type variant

SUBHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
- [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00

4S when size = 01

2D when size = 10

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;

```

## C7.2.294 SUQADD

Signed saturating Accumulate of Unsigned value. This instruction adds the unsigned integer values of the vector elements in the source SIMD&FP register to corresponding signed integer values of the vector elements in the destination SIMD&FP register, and writes the resulting signed integer values to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9				5	4				0

U																															

### Vector variant

SUQADD <Vd>.<T>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

### Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

B when size = 00

H	when size = 01
S	when size = 10
D	when size = 11
<d>	Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<n>	Is the number of the SIMD&FP source register, encoded in the "Rn" field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1
2D	when size = 11, Q = 1
	The encoding size = 11, Q = 0 is reserved.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(datasize) operand2 = V[d];
integer op1;
integer op2;
boolean sat;

for e = 0 to elements-1
    op1 = Int(Elem[operand, e, esize], !unsigned);
    op2 = Int(Elem[operand2, e, esize], unsigned);
    (Elem[result, e, esize], sat) = SatQ(op1 + op2, esize, unsigned);
    if sat then FPSR.QC = '1';
V[d] = result;

```

## C7.2.295 SXTL, SXTL2

Signed extend Long. This instruction duplicates each vector element in the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SXTL instruction extracts the source vector from the lower half of the source register, while the SXTL2 instruction extracts the source vector from the upper half of the source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the SSHLL, SSHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of SSHLL, SSHLL2.
- The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	1	0	!=0000	0	0	0	1	0	1	0	0	1		Rn		Rd
U									immh			immb										

### Vector variant

SXTL{2} <Vd>.<Ta>, <Vn>.<Tb>

is equivalent to

SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #0

and is the preferred disassembly when BitCount(immh) == 1.

### Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0  
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001  
4S when immh = 001x  
2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0  
16B when immh = 0001, Q = 1  
4H when immh = 001x, Q = 0  
8H when immh = 001x, Q = 1

2S            when immh = 01xx, Q = 0

4S            when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

## Operation

The description of [SSHLL](#), [SSHLL2](#) gives the operational pseudocode for this instruction.

## C7.2.296 TBL

Table vector Lookup. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the result for that lookup is 0. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Two register table variant

Applies when `len == 01`.

TBL `<Vd>.<Ta>`, { `<Vn>.16B`, `<Vn+1>.16B` }, `<Vm>.<Ta>`

### Three register table variant

Applies when `len == 10`.

TBL `<Vd>.<Ta>`, { `<Vn>.16B`, `<Vn+1>.16B`, `<Vn+2>.16B` }, `<Vm>.<Ta>`

### Four register table variant

Applies when `len == 11`.

TBL `<Vd>.<Ta>`, { `<Vn>.16B`, `<Vn+1>.16B`, `<Vn+2>.16B`, `<Vn+3>.16B` }, `<Vm>.<Ta>`

### Single register table variant

Applies when `len == 00`.

TBL `<Vd>.<Ta>`, { `<Vn>.16B` }, `<Vm>.<Ta>`

### Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');
```

### Assembler symbols

<code>&lt;Vd&gt;</code>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<code>&lt;Ta&gt;</code>	Is an arrangement specifier, encoded in the "Q" field. It can have the following values: <div style="margin-left: 20px;"> 8B            when Q = 0  16B          when Q = 1 </div>
<code>&lt;Vn&gt;</code>	For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.

For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.

- <Vn+1> Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.
- <Vn+2> Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.
- <Vn+3> Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.
- <Vm> Is the name of the SIMD&FP index register, encoded in the "Rm" field.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bits(128*regs) table = Zeros();
bits(datasize) result;
integer index;
integer i;

// Create table from registers
for i = 0 to regs-1
    table<128*i+127:128*i> = V[n];
    n = (n + 1) MOD 32;

result = if is_tbl then Zeros() else V[d];
for i = 0 to elements-1
    index = UInt(Elem[indices, i, 8]);
    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;

```

## C7.2.297 TBX

Table vector lookup extension. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the existing value in the vector element of the destination register is left unchanged. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Two register table variant

Applies when `len == 01`.

TBX `<Vd>.<Ta>`, { `<Vn>.16B`, `<Vn+1>.16B` }, `<Vm>.<Ta>`

### Three register table variant

Applies when `len == 10`.

TBX `<Vd>.<Ta>`, { `<Vn>.16B`, `<Vn+1>.16B`, `<Vn+2>.16B` }, `<Vm>.<Ta>`

### Four register table variant

Applies when `len == 11`.

TBX `<Vd>.<Ta>`, { `<Vn>.16B`, `<Vn+1>.16B`, `<Vn+2>.16B`, `<Vn+3>.16B` }, `<Vm>.<Ta>`

### Single register table variant

Applies when `len == 00`.

TBX `<Vd>.<Ta>`, { `<Vn>.16B` }, `<Vm>.<Ta>`

### Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');
```

### Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

8B	when Q = 0
16B	when Q = 1

- <Vn> For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.  
For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.
- <Vn+1> Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.
- <Vn+2> Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.
- <Vn+3> Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.
- <Vm> Is the name of the SIMD&FP index register, encoded in the "Rm" field.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bits(128*regs) table = Zeros();
bits(datasize) result;
integer index;
integer i;

// Create table from registers
for i = 0 to regs-1
    table<128*i+127:128*i> = V[n];
    n = (n + 1) MOD 32;

result = if is_tbl then Zeros() else V[d];
for i = 0 to elements-1
    index = UInt(Elem[indices, i, 8]);
    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;

```

## C7.2.298 TRN1

Transpose vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

### Note

By using this instruction with TRN2, a 2 x 2 matrix can be transposed.

The following figure shows the operation of TRN1 and TRN2 halfword operations where Q = 0.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

TRN1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
2D            when size = 11, Q = 1  
The encoding size = 11, Q = 0 is reserved.

<Vn>            Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer p;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, 2*p+part, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, 2*p+part, esize];

V[d] = result;
```

## C7.2.299 TRN2

Transpose vectors (secondary). This instruction reads corresponding odd-numbered vector elements from the two source SIMD&FP registers, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

### ———— Note ————

By using this instruction with TRN1, a 2 x 2 matrix can be transposed.

The following figure shows the operation of TRN1 and TRN2 halfword operations where Q = 0.

TRN1.16

TRN2.16

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

TRN2 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
2D            when size = 11, Q = 1  
The encoding size = 11, Q = 0 is reserved.

<Vn>            Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer p;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, 2*p+part, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, 2*p+part, esize];

V[d] = result;
```

## C7.2.300 UABA

Unsigned Absolute difference and Accumulate. This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the elements of the vector of the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

UABA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean accumulate = (ac == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) absdiff;
```

```
result = if accumulate then V[d] else Zeros();  
for e = 0 to elements-1  
    element1 = Int(Elem[operand1, e, esize], unsigned);  
    element2 = Int(Elem[operand2, e, esize], unsigned);  
    absdiff = Abs(element1-element2)<esize-1:0>;  
    Elem[result, e, esize] = Elem[result, e, esize] + absdiff;  
V[d] = result;
```

## C7.2.301 UABAL, UABAL2

Unsigned Absolute difference and Accumulate Long. This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The UABAL instruction extracts each source vector from the lower half of each source register, while the UABAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

UABAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean accumulate = (op == '0');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00  
4S when size = 01  
2D when size = 10  
The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0

16B        when size = 00, Q = 1  
4H        when size = 01, Q = 0  
8H        when size = 01, Q = 1  
2S        when size = 10, Q = 0  
4S        when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>        Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) absdiff;

result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

## C7.2.302 UABD

Unsigned Absolute Difference (vector). This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, places the absolute values of the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

UABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean accumulate = (ac == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) absdiff;
```

```
result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<esize-1:0>;
    Elem[result, e, esize] = Elem[result, e, esize] + absdiff;
V[d] = result;
```

## C7.2.303 UABDL, UABDL2

Unsigned Absolute Difference Long. This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, places the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The UABDL instruction extracts each source vector from the lower half of each source register, while the UABDL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

UABDL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean accumulate = (op == '0');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
  - 4S when size = 01
  - 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0

16B        when size = 00, Q = 1  
4H        when size = 01, Q = 0  
8H        when size = 01, Q = 1  
2S        when size = 10, Q = 0  
4S        when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>        Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) absdiff;

result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

## C7.2.304 UADALP

Unsigned Add and Accumulate Long Pairwise. This instruction adds pairs of adjacent unsigned integer values from the vector in the source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

UADALP <Vd>.<Ta>, <Vn>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV (2 * esize);
boolean acc = (op == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |    |                       |
|----|-----------------------|
| 4H | when size = 00, Q = 0 |
| 8H | when size = 00, Q = 1 |
| 2S | when size = 01, Q = 0 |
| 4S | when size = 01, Q = 1 |
| 1D | when size = 10, Q = 0 |
| 2D | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(2*esize) sum;
integer op1;
integer op2;

result = if acc then V[d] else Zeros();
for e = 0 to elements-1
    op1 = Int(Elem[operand, 2*e+0, esize], unsigned);
    op2 = Int(Elem[operand, 2*e+1, esize], unsigned);
    sum = (op1+op2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + sum;

V[d] = result;
```

## C7.2.305 UADDL, UADDL2

Unsigned Add Long (vector). This instruction adds each vector element in the lower or upper half of the first source SIMD&FP register to the corresponding vector element of the second source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The UADDL instruction extracts each source vector from the lower half of each source register, while the UADDL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

UADDL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00  
4S when size = 01  
2D when size = 10  
The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0  
16B when size = 00, Q = 1

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

## C7.2.306 UADDLP

Unsigned Add Long Pairwise. This instruction adds pairs of adjacent unsigned integer values from the vector in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

UADDLP <Vd>.<Ta>, <Vn>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV (2 * esize);
boolean acc = (op == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |    |                       |
|----|-----------------------|
| 4H | when size = 00, Q = 0 |
| 8H | when size = 00, Q = 1 |
| 2S | when size = 01, Q = 0 |
| 4S | when size = 01, Q = 1 |
| 1D | when size = 10, Q = 0 |
| 2D | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(2*esize) sum;
integer op1;
integer op2;

result = if acc then V[d] else Zeros();
for e = 0 to elements-1
    op1 = Int(Elem[operand, 2*e+0, esize], unsigned);
    op2 = Int(Elem[operand, 2*e+1, esize], unsigned);
    sum = (op1+op2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + sum;

V[d] = result;
```

## C7.2.307 UADDLV

Unsigned sum Long across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

UADDLV <V><d>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

### Assembler symbols

- <V>            Is the destination width specifier, encoded in the "size" field. It can have the following values:
- |   |                |
|---|----------------|
| H | when size = 00 |
| S | when size = 01 |
| D | when size = 10 |
- The encoding size = 11 is reserved.
- <d>            Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- <Vn>           Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <T>            Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 4S  | when size = 10, Q = 1 |
- The following encodings are reserved:
- size = 10, Q = 0.
  - size = 11, Q = x.

## Operation

```
CheckFPAdvSIMDEnabled64();  
bits(datasize) operand = V[n];  
integer sum;  
  
sum = Int(Elem[operand, 0, esize], unsigned);  
for e = 1 to elements-1  
    sum = sum + Int(Elem[operand, e, esize], unsigned);  
  
V[d] = sum<2*esize-1:0>;
```

## C7.2.308 UADDW, UADDW2

Unsigned Add Wide. This instruction adds the vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register. All the values in this instruction are unsigned integer values.

The UADDW instruction extracts vector elements from the lower half of the second source register, while the UADDW2 instruction extracts vector elements from the upper half of the second source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

UADDW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
  - 4S when size = 01
  - 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;

```

## C7.2.309 UCVTF (vector, fixed-point)

Unsigned fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the [FPCR](#), and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#), or a synchronous exception being generated. For more information, see [Floating-point exceptions and exception traps on page D1-1831](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

### Scalar

31	30	29	28	27	26	25	24	23	22		19	18	16	15	14	13	12	11	10	9		5	4		0
0	1	1	1	1	1	1	1	0	!	=0000			immb	1	1	1	0	0	1			Rn			Rd
U										immh															

### Scalar variant

UCVTF <V><d>, <V><n>, #<fbits>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '000x' || (immh == '001x' && !HaveFP16Ext()) then ReservedValue();
integer esize = if immh == '1xxx' then 64 else if immh == '01xx' then 32 else 16;
integer datasize = esize;
integer elements = 1;

integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);
```

### Vector

31	30	29	28	27	26	25	24	23	22		19	18	16	15	14	13	12	11	10	9		5	4		0
0	Q	1	0	1	1	1	1	0	!	=0000			immb	1	1	1	0	0	1			Rn			Rd
U										immh															

### Vector variant

UCVTF <Vd>.<T>, <Vn>.<T>, #<fbits>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh == '000x' || (immh == '001x' && !HaveFP16Ext()) then ReservedValue();
if immh<3>:Q == '10' then ReservedValue();
integer esize = if immh == '1xxx' then 64 else if immh == '01xx' then 32 else 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);
```

## Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
- |   |                  |
|---|------------------|
| H | when immh = 001x |
| S | when immh = 01xx |
| D | when immh = 1xxx |
- The encoding immh = 000x is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- |    |                         |
|----|-------------------------|
| 4H | when immh = 001x, Q = 0 |
| 8H | when immh = 001x, Q = 1 |
| 2S | when immh = 01xx, Q = 0 |
| 4S | when immh = 01xx, Q = 1 |
| 2D | when immh = 1xxx, Q = 1 |
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.
- The following encodings are reserved:
- immh = 0001, Q = x.
  - immh = 1xxx, Q = 0.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:
- |                       |                  |
|-----------------------|------------------|
| (32-UInt(immh:immb))  | when immh = 001x |
| (64-UInt(immh:immb))  | when immh = 01xx |
| (128-UInt(immh:immb)) | when immh = 1xxx |
- The encoding immh = 000x is reserved.
- For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:
- |                       |                  |
|-----------------------|------------------|
| (32-UInt(immh:immb))  | when immh = 001x |
| (64-UInt(immh:immb))  | when immh = 01xx |
| (128-UInt(immh:immb)) | when immh = 1xxx |
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.
- The encoding immh = 0001 is reserved.

## Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
```

```
element = Elem[operand, e, esize];  
Elem[result, e, esize] = FixedToFP(element, fracbits, unsigned, FPCR, rounding);  
V[d] = result;
```

## C7.2.310 UCVTF (vector, integer)

Unsigned integer Convert to Floating-point (vector). This instruction converts each element in a vector from an unsigned integer value to a floating-point value using the rounding mode that is specified by the [FPCR](#), and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#), or a synchronous exception being generated. For more information, see [Floating-point exceptions and exception traps on page D1-1831](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

    if HaveFP16Ext() then
      fltsize = 16;
    else
      UnallocatedEncoding();

rounding = FPRoundingMode(FPCR);

```

### Assembler symbols

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

### Operation

```

CheckFPAdvSIMDEnabled64();

bits(fltsize) fltval;
bits(intsize) intval;

intval = X[n];
fltval = FixedToFP(intval, 0, TRUE, FPCR, rounding);
V[d] = fltval;

```

### C7.2.313 UHADD

Unsigned Halving Add. This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see [URHADD](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Three registers of the same type variant

UHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

#### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

#### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    Elem[result, e, esize] = sum<esize:1>;

V[d] = result;
```

## C7.2.314 UHSUB

Unsigned Halving Subtract. This instruction subtracts the vector elements in the second source SIMD&FP register from the corresponding vector elements in the first source SIMD&FP register, shifts each result right one bit, places each result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

UHSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
```

```
element2 = Int(Elm[operand2, e, esize], unsigned);  
diff = element1 - element2;  
Elm[result, e, esize] = diff<esize:1>;  
  
V[d] = result;
```

## C7.2.315 UMAX

Unsigned Maximum (vector). This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the larger of each pair of unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

UMAX <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer maxmin;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
    Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
```

## C7.2.316 UMAXP

Unsigned Maximum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

UMAXP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
integer element1;
integer element2;
```

```
integer maxmin;  
  
for e = 0 to elements-1  
    element1 = Int(Elem[concat, 2*e, esize], unsigned);  
    element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);  
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);  
    Elem[result, e, esize] = maxmin<esize-1:0>;  
  
V[d] = result;
```

## C7.2.317 UMAXV

Unsigned Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

UMAXV <V><d>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');
```

### Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:

B	when size = 00
H	when size = 01
S	when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
4S	when size = 10, Q = 1

The following encodings are reserved:

- size = 10, Q = 0.
- size = 11, Q = x.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin<esize-1:0>;
```

## C7.2.318 UMIN

Unsigned Minimum (vector). This instruction compares corresponding vector elements in the two source SIMD&FP registers, places the smaller of each of the two unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

UMIN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer maxmin;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
    Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
```

## C7.2.319 UMINP

Unsigned Minimum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

UMINP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
integer element1;
integer element2;
```

```
integer maxmin;  
  
for e = 0 to elements-1  
    element1 = Int(Elem[concat, 2*e, esize], unsigned);  
    element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);  
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);  
    Elem[result, e, esize] = maxmin<esize-1:0>;  
  
V[d] = result;
```

## C7.2.320 UMINV

Unsigned Minimum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

UMINV <V><d>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');
```

### Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:

B	when size = 00
H	when size = 01
S	when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
4S	when size = 10, Q = 1

The following encodings are reserved:

- size = 10, Q = 0.
- size = 11, Q = x.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin<esize-1:0>;
```

## C7.2.321 UMLAL, UMLAL2 (by element)

Unsigned Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLAL instruction extracts vector elements from the lower half of the first source register, while the UMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

UMLAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

### Decode for this encoding

```

integer idxsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
    
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 4S when size = 01
  - 2D when size = 10
- The following encodings are reserved:
- size = 00.

- size = 11.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1
- The following encodings are reserved:
- size = 00, Q = x.
  - size = 11, Q = x.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- 0:Rm          when size = 01  
M:Rm          when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.
- Restricted to V0-V15 when element size <Ts> is H.
- <Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
- H            when size = 01  
S            when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.
- <index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- H:L:M        when size = 01  
H:L          when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsizesize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else

```

```
Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] + product;  
V[d] = result;
```

## C7.2.322 UMLAL, UMLAL2 (vector)

Unsigned Multiply-Add Long (vector). This instruction multiplies the vector elements in the lower or upper half of the first source SIMD&FP register by the corresponding vector elements of the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLAL instruction extracts vector elements from the lower half of the first source register, while the UMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

UMLAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
  - 4S when size = 01
  - 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;

V[d] = result;
```

### C7.2.323 UMLSL, UMLSL2 (by element)

Unsigned Multiply-Subtract Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLSL instruction extracts vector elements from the lower half of the first source register, while the UMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Vector variant

UMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

#### Decode for this encoding

```

integer idxsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
```

#### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
  - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 4S when size = 01
  - 2D when size = 10
- The following encodings are reserved:
- size = 00.

- size = 11.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 4H            when size = 01, Q = 0
- 8H            when size = 01, Q = 1
- 2S            when size = 10, Q = 0
- 4S            when size = 10, Q = 1
- The following encodings are reserved:
- size = 00, Q = x.
  - size = 11, Q = x.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- 0:Rm          when size = 01
- M:Rm          when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.
- Restricted to V0-V15 when element size <Ts> is H.
- <Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
- H            when size = 01
- S            when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.
- <index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- H:L:M        when size = 01
- H:L          when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsizesize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else

```

```
Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] + product;  
V[d] = result;
```

## C7.2.324 UMLSL, UMLSL2 (vector)

Unsigned Multiply-Subtract Long (vector). This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are unsigned integer values.

The UMLSL instruction extracts each source vector from the lower half of each source register, while the UMLSL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

UMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
- [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
- 4S when size = 01
- 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;

V[d] = result;
```

## C7.2.325 UMOV

Unsigned Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias [MOV \(to general\)](#). See [Alias conditions](#) for details of when each alias is preferred.

31	30	29	28	27	26	25	24	23	22	21	20	16	15	14	13	12	11	10	9	5	4	0
0	Q	0	0	1	1	1	0	0	0	0	0	imm5	0	0	1	1	1	1	1	Rn	Rd	

### 32-bit variant

Applies when Q == 0.

UMOV <Wd>, <Vn>.<Ts>[<index>]

### 64-bit variant

Applies when Q == 1 && imm5 == x1000.

UMOV <Xd>, <Vn>.<Ts>[<index>]

### Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size;
case Q:imm5 of
  when '0xxx1' size = 0;    // UMOV Wd, Vn.B
  when '0xxx10' size = 1;   // UMOV Wd, Vn.H
  when '0xx100' size = 2;   // UMOV Wd, Vn.S
  when '1x1000' size = 3;   // UMOV Xd, Vn.D
  otherwise UnallocatedEncoding();

integer idxsize = if imm5<4> == '1' then 128 else 64;
integer index = UInt(imm5<4>:size+1>);
integer esize = 8 << size;
integer datasize = if Q == '1' then 64 else 32;
```

### Alias conditions

Alias	is preferred when
<a href="#">MOV (to general)</a>	imm5 == 'x1000'
<a href="#">MOV (to general)</a>	imm5 == 'xx100'

### Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<Ts>	<p>For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:</p> <p>B           when imm5 = xxxx1</p> <p>H           when imm5 = xxx10</p> <p>S           when imm5 = xx100</p> <p>The encoding imm5 = xx000 is reserved.</p> <p>For the 64-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:</p> <p>D           when imm5 = x1000</p> <p>The following encodings are reserved:</p> <ul style="list-style-type: none"> <li>• imm5 = x0000.</li> <li>• imm5 = xxxx1.</li> <li>• imm5 = xxx10.</li> <li>• imm5 = xx100.</li> </ul>
<index>	<p>For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:</p> <p>imm5&lt;4:1&gt; when imm5 = xxxx1</p> <p>imm5&lt;4:2&gt; when imm5 = xxx10</p> <p>imm5&lt;4:3&gt; when imm5 = xx100</p> <p>The encoding imm5 = xx000 is reserved.</p> <p>For the 64-bit variant: is the element index encoded in "imm5&lt;4&gt;".</p>

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(idxsiz) operand = V[n];

X[d] = ZeroExtend(Elm[operand, index, esize], datasize);

```

## C7.2.326 UMULL, UMULL2 (by element)

Unsigned Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMULL instruction extracts vector elements from the lower half of the first source register, while the UMULL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

UMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

### Decode for this encoding

```

integer idxsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 4S when size = 01  
2D when size = 10
- The following encodings are reserved:
- size = 00.
  - size = 11.

<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Tb>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: 4H           when size = 01, Q = 0 8H           when size = 01, Q = 1 2S           when size = 10, Q = 0 4S           when size = 10, Q = 1 The following encodings are reserved: •     size = 00, Q = x. •     size = 11, Q = x.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values: 0:Rm         when size = 01 M:Rm         when size = 10 The following encodings are reserved: •     size = 00. •     size = 11. Restricted to V0-V15 when element size <Ts> is H.
<Ts>	Is an element size specifier, encoded in the "size" field. It can have the following values: H            when size = 01 S            when size = 10 The following encodings are reserved: •     size = 00. •     size = 11.
<index>	Is the element index, encoded in the "size:L:H:M" field. It can have the following values: H:L:M        when size = 01 H:L           when size = 10 The following encodings are reserved: •     size = 00. •     size = 11.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsizesize) operand2 = V[m];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = product;

V[d] = result;
```

## C7.2.327 UMULL, UMULL2 (vector)

Unsigned Multiply long (vector). This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are unsigned integer values.

The UMULL instruction extracts each source vector from the lower half of each source register, while the UMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

UMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00  
4S when size = 01  
2D when size = 10  
The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0  
16B when size = 00, Q = 1

4H        when size = 01, Q = 0  
8H        when size = 01, Q = 1  
2S        when size = 10, Q = 0  
4S        when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>        Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, 2*esize] = (element1*element2)<2*esize-1:0>;

V[d] = result;
```

## C7.2.328 UQADD

Unsigned saturating Add. This instruction adds the values of corresponding elements of the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

UQADD <V><d>, <V><n>, <V><m>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
```

### Vector

### Vector variant

UQADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

### Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

B	when size = 00
H	when size = 01
S	when size = 10

	D	when size = 11
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.	
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.	
<m>	Is the number of the second SIMD&FP source register, encoded in the "Rm" field.	
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.	
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:	
	8B	when size = 00, Q = 0
	16B	when size = 00, Q = 1
	4H	when size = 01, Q = 0
	8H	when size = 01, Q = 1
	2S	when size = 10, Q = 0
	4S	when size = 10, Q = 1
	2D	when size = 11, Q = 1
	The encoding size = 11, Q = 0 is reserved.	
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.	
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.	

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
boolean sat;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    (Elem[result, e, esize], sat) = SatQ(sum, esize, unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;

```

## C7.2.329 UQRSHL

Unsigned saturating Rounding Shift Left (register). This instruction takes each vector element of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see [UQSHL \(immediate\)](#).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Vector variant

UQRSHL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
```

## Assembler symbols

<V>	Is a width specifier, encoded in the "size" field. It can have the following values:
B	when size = 00
H	when size = 01
S	when size = 10
D	when size = 11
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<m>	Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1
2D	when size = 11, Q = 1
	The encoding size = 11, Q = 0 is reserved.
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1);    // 0 for left shift, 2^(n-1) for right shift
    element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;

```

## C7.2.330 UQRSHRN, UQRSHRN2

Unsigned saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see [UQSHRN](#), [UQSHRN2](#).

The UQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
```

```
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
boolean unsigned = (U == '1');
```

## Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- 8B when immh = 0001, Q = 0  
16B when immh = 0001, Q = 1  
4H when immh = 001x, Q = 0  
8H when immh = 001x, Q = 1  
2S when immh = 01xx, Q = 0  
4S when immh = 01xx, Q = 1
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.  
The encoding immh = 1xxx, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
- 8H when immh = 0001  
4S when immh = 001x  
2D when immh = 01xx
- See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.  
The encoding immh = 1xxx is reserved.
- <Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:
- B when immh = 0001  
H when immh = 001x  
S when immh = 01xx
- The following encodings are reserved:
- immh = 0000.
  - immh = 1xxx.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:
- H when immh = 0001  
S when immh = 001x  
D when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;

```

### C7.2.331 UQSHL (immediate)

Unsigned saturating Shift Left (immediate). This instruction takes each vector element in the source SIMD&FP register, shifts it by an immediate value, places the results in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see [UQRSHL](#).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

## Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], src_unsigned) << shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```

## C7.2.332 UQSHL (register)

Unsigned saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see [UQRSHL](#).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;

```

### C7.2.333 UQSHRN, UQSHRN2

Unsigned saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see [UQRSHRN](#), [UQRSHRN2](#).

The UQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

## Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0  
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0  
16B when immh = 0001, Q = 1  
4H when immh = 001x, Q = 0  
8H when immh = 001x, Q = 1  
2S when immh = 01xx, Q = 0  
4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001  
4S when immh = 001x  
2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001  
H when immh = 001x  
S when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001  
S when immh = 001x  
D when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;

```

## C7.2.334 UQSUB

Unsigned saturating Subtract. This instruction subtracts the element values of the second source SIMD&FP register from the corresponding element values of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';

V[d] = result;

```

### C7.2.335 UQXTN, UQXTN2

Unsigned saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates each value to half the original width, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The UQXTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQXTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

boolean unsigned = (U == '1');
```

## Assembler symbols

2	Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values: [absent] when Q = 0 [present] when Q = 1
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Tb>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: 8B when size = 00, Q = 0 16B when size = 00, Q = 1 4H when size = 01, Q = 0 8H when size = 01, Q = 1 2S when size = 10, Q = 0 4S when size = 10, Q = 1 The encoding size = 11, Q = x is reserved.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<Ta>	Is an arrangement specifier, encoded in the "size" field. It can have the following values: 8H when size = 00 4S when size = 01 2D when size = 10 The encoding size = 11 is reserved.
<Vb>	Is the destination width specifier, encoded in the "size" field. It can have the following values: B when size = 00 H when size = 01 S when size = 10 The encoding size = 11 is reserved.
<d>	Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<Va>	Is the source width specifier, encoded in the "size" field. It can have the following values: H when size = 00 S when size = 01 D when size = 10 The encoding size = 11 is reserved.
<n>	Is the number of the SIMD&FP source register, encoded in the "Rn" field.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;
boolean sat;

for e = 0 to elements-1
    element = E1em[operand, e, 2*esize];
    (E1em[result, e, esize], sat) = SatQ(Int(element, unsigned), esize, unsigned);

```

```
if sat then FPSR.QC = '1';  
Vpart[d, part] = result;
```

## C7.2.336 URECPE

Unsigned Reciprocal Estimate. This instruction reads each vector element from the source SIMD&FP register, calculates an approximate inverse for the unsigned integer value, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9				5	4			0
0	Q	0	0	1	1	1	0	1	sz	1	0	0	0	0	1	1	1	0	0	1	0						Rn			Rd

### Vector variant

URECPE <Vd>.<T>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '1' then ReservedValue();
integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S	when sz = 0, Q = 0
4S	when sz = 0, Q = 1

The encoding sz = 1, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(32) element;

for e = 0 to elements-1
    element = Elem[operand, e, 32];
    Elem[result, e, 32] = UnsignedRecipEstimate(element);

V[d] = result;
```

### C7.2.337 URHADD

Unsigned Rounding Halving Add. This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see [UHADD](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Three registers of the same type variant

URHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

#### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

#### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

#### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, esize] = (element1+element2+1)<esize:1>;

V[d] = result;
```

## C7.2.338 URSHL

Unsigned Rounding Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

URSHL <V><d>, <V><n>, <V><m>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
if S == '0' && size != '11' then ReservedValue();
```

### Vector

### Vector variant

URSHL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
```

## Assembler symbols

<V>	Is a width specifier, encoded in the "size" field. It can have the following values: D            when size = 11 The following encodings are reserved: <ul style="list-style-type: none"> <li>size = 0x.</li> <li>size = 10.</li> </ul>
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

### Vector variant

URSQRTE <Vd>.<T>, <Vn>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '1' then ReservedValue();
integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S	when sz = 0, Q = 0
4S	when sz = 0, Q = 1

The encoding sz = 1, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(32) element;

for e = 0 to elements-1
    element = Elem[operand, e, 32];
    Elem[result, e, 32] = UnsignedRSqrtEstimate(element);

V[d] = result;
```

## C7.2.341 URSRA

Unsigned Rounding Shift Right and Accumulate (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see [USRA](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

## Assembler symbols

<V>	Is a width specifier, encoded in the "immh" field. It can have the following values: D           when immh = 1xxx The encoding immh = 0xxx is reserved.
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values: 8B           when immh = 0001, Q = 0 16B          when immh = 0001, Q = 1 4H           when immh = 001x, Q = 0 8H           when immh = 001x, Q = 1 2S           when immh = 01xx, Q = 0 4S           when immh = 01xx, Q = 1 2D           when immh = 1xxx, Q = 1 See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when immh = 0000, Q = x. The encoding immh = 1xxx, Q = 0 is reserved.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<shift>	For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values: (128-UInt(immh:immb)) when immh = 1xxx The encoding immh = 0xxx is reserved. For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values: (16-UInt(immh:immb))   when immh = 0001 (32-UInt(immh:immb))   when immh = 001x (64-UInt(immh:immb))   when immh = 01xx (128-UInt(immh:immb))  when immh = 1xxx See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when immh = 0000.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;

```

## C7.2.342 USHL

Unsigned Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see [URSHL](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Scalar variant

USHL <V><d>, <V><n>, <V><m>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
if S == '0' && size != '11' then ReservedValue();
```

### Vector

### Vector variant

USHL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
```

## Assembler symbols

<V>	Is a width specifier, encoded in the "size" field. It can have the following values: D           when size = 11 The following encodings are reserved: •       size = 0x. •       size = 10.
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<m>	Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: 8B       when size = 00, Q = 0 16B      when size = 00, Q = 1 4H       when size = 01, Q = 0 8H       when size = 01, Q = 1 2S       when size = 10, Q = 0 4S       when size = 10, Q = 1 2D       when size = 11, Q = 1 The encoding size = 11, Q = 0 is reserved.
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1);    // 0 for left shift, 2^(n-1) for right shift
    element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;

```

## C7.2.343 USHLL, USHLL2

Unsigned Shift Left Long (immediate). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, shifts the unsigned integer value left by the specified number of bits, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The USHLL instruction extracts vector elements from the lower half of the source register, while the USHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias UXTL, UXTL2. See *Alias conditions* for details of when each alias is preferred.

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	1	0	1	1	1	1	0	!=0000	immb	1	0	1	0	0	1	Rn				Rd	
U										immh												

### Vector variant

USHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
boolean unsigned = (U == '1');
```

### Alias conditions

Alias	is preferred when
UXTL, UXTL2	immb == '000' && BitCount(immh) == 1

### Assembler symbols

2	Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values: [absent] when Q = 0 [present] when Q = 1
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta>	Is an arrangement specifier, encoded in the "immh" field. It can have the following values: 8H when immh = 0001 4S when immh = 001x

2D            when immh = 01xx

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn>            Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb>            Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B            when immh = 0001, Q = 0

16B           when immh = 0001, Q = 1

4H            when immh = 001x, Q = 0

8H            when immh = 001x, Q = 1

2S            when immh = 01xx, Q = 0

4S            when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<shift>            Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

(UInt(immh:immb)-8)    when immh = 0001

(UInt(immh:immb)-16)    when immh = 001x

(UInt(immh:immb)-32)    when immh = 01xx

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

## C7.2.344 USHR

Unsigned Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see [URSHR](#).

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;

```

## C7.2.345 USQADD

Unsigned saturating Accumulate of Signed value. This instruction adds the signed integer values of the vector elements in the source SIMD&FP register to corresponding unsigned integer values of the vector elements in the destination SIMD&FP register, and accumulates the resulting unsigned integer values with the vector elements of the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;

```

## C7.2.347 USUBL, USUBL2

Unsigned Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The destination vector elements are twice as long as the source vector elements.

The USUBL instruction extracts each source vector from the lower half of each source register, while the USUBL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

USUBL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0  
[present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00  
4S when size = 01  
2D when size = 10  
The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0  
16B when size = 00, Q = 1

4H            when size = 01, Q = 0  
8H            when size = 01, Q = 1  
2S            when size = 10, Q = 0  
4S            when size = 10, Q = 1  
The encoding size = 11, Q = x is reserved.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

## C7.2.348 USUBW, USUBW2

Unsigned Subtract Wide. This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element in the lower or upper half of the first source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. All the values in this instruction are signed integer values.

The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register.

The USUBW instruction extracts vector elements from the lower half of the first source register, while the USUBW2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR\_EL1, CPTR\_EL2, and CPTR\_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type variant

USUBW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- |           |            |
|-----------|------------|
| [absent]  | when Q = 0 |
| [present] | when Q = 1 |
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- |    |                |
|----|----------------|
| 8H | when size = 00 |
| 4S | when size = 01 |
| 2D | when size = 10 |
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

## Operation

```

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;

```

## C7.2.349 UXTL, UXTL2

Unsigned extend Long. This instruction copies each vector element from the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The UXTL instruction extracts vector elements from the lower half of the source register, while the UXTL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the [USHLL](#), [USHLL2](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [USHLL](#), [USHLL2](#).
- The description of [USHLL](#), [USHLL2](#) gives the operational pseudocode for this instruction.

31	30	29	28	27	26	25	24	23	22	19	18	16	15	14	13	12	11	10	9	5	4	0
0	Q	1	0	1	1	1	1	0	!=0000	0	0	0	1	0	1	0	0	1		Rn		Rd
U									immh			immb										

### Vector variant

UXTL{2} <Vd>.<Ta>, <Vn>.<Tb>

is equivalent to

USHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #0

and is the preferred disassembly when  $\text{BitCount}(\text{immh}) = 1$ .

### Assembler symbols

2	Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values: [absent] when Q = 0 [present] when Q = 1
<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta>	Is an arrangement specifier, encoded in the "immh" field. It can have the following values: 8H when immh = 0001 4S when immh = 001x 2D when immh = 01xx See <a href="#">Advanced SIMD modified immediate on page C4-291</a> when immh = 0000. The encoding immh = 1xxx is reserved.
<Vn>	Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<Tb>	Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values: 8B when immh = 0001, Q = 0 16B when immh = 0001, Q = 1 4H when immh = 001x, Q = 0 8H when immh = 001x, Q = 1

2S            when immh = 01xx, Q = 0

4S            when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-291](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

## Operation

The description of [USHLL](#), [USHLL2](#) gives the operational pseudocode for this instruction.

## C7.2.350 UZP1

Unzip vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

### ———— Note ————

This instruction can be used with UZP2 to de-interleave two vectors.

The following figure shows the operation of UZP1 and UZP2 with the arrangement specifier 8B.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

UZP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
```

### Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

2D            when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn>            Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operandl = V[n];
bits(datasize) operandh = V[m];
bits(datasize) result;
integer e;

bits(datasize*2) zipped = operandh:operandl;
for e = 0 to elements-1
    Elem[result, e, esize] = Elem[zipped, 2*e+part, esize];

V[d] = result;
```

## C7.2.351 UZP2

Unzip vectors (secondary). This instruction reads corresponding odd-numbered vector elements from the two source SIMD&FP registers, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

### ———— Note ————

This instruction can be used with UZP1 to de-interleave two vectors.

The following figure shows the operation of UZP1 and UZP2 with the arrangement specifier 8B.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

UZP2 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
```

### Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>	Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

2D            when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn>            Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operandl = V[n];
bits(datasize) operandh = V[m];
bits(datasize) result;
integer e;

bits(datasize*2) zipped = operandh:operandl;
for e = 0 to elements-1
    Elem[result, e, esize] = Elem[zipped, 2*e+part, esize];

V[d] = result;
```

## C7.2.352 XTN, XTN2

Extract Narrow. This instruction reads each vector element from the source SIMD&FP register, narrows each value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

The XTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the XTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9				5	4				0
0	Q	0	0	1	1	1	0	size	1	0	0	0	0	1	0	0	1	0	1	0							Rn				Rd

### Vector variant

XTN{2} <Vd>.<Tb>, <Vn>.<Ta>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- |           |            |
|-----------|------------|
| [absent]  | when Q = 0 |
| [present] | when Q = 1 |
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |
| 4S  | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- |    |                |
|----|----------------|
| 8H | when size = 00 |
|----|----------------|

4S            when size = 01  
2D            when size = 10  
The encoding size = 11 is reserved.

## Operation

```
CheckFPAdvSIMDEnabled64();  
bits(2*datasize) operand = V[n];  
bits(datasize) result;  
bits(2*esize) element;  
  
for e = 0 to elements-1  
    element = Elem[operand, e, 2*esize];  
    Elem[result, e, esize] = element<esize-1:0>;  
Vpart[d, part] = result;
```

## C7.2.353 ZIP1

Zip vectors (primary). This instruction reads adjacent vector elements from the upper half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

### ———— Note ————

This instruction can be used with ZIP2 to interleave two vectors.

The following figure shows the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

ZIP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |
| 2S  | when size = 10, Q = 0 |

4S            when size = 10, Q = 1  
2D            when size = 11, Q = 1  
The encoding size = 11, Q = 0 is reserved.

<Vn>            Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>            Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

## Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer base = part * pairs;
integer p;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, base+p, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, base+p, esize];

V[d] = result;
```

## C7.2.354 ZIP2

Zip vectors (secondary). This instruction reads adjacent vector elements from the lower half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

### ———— Note ————

This instruction can be used with ZIP1 to interleave two vectors.

The following figure shows the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

Depending on the settings in the [CPACR\\_EL1](#), [CPTR\\_EL2](#), and [CPTR\\_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

ZIP2 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

### Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- |     |                       |
|-----|-----------------------|
| 8B  | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H  | when size = 01, Q = 0 |
| 8H  | when size = 01, Q = 1 |

## **The AArch64 System Level Architecture**

# Chapter D1

## The AArch64 System Level Programmers' Model

This chapter describes the AArch64 system level programmers' model. It contains the following sections:

- *Exception levels on page D1-1776.*
- *Exception terminology on page D1-1777.*
- *Execution state on page D1-1779.*
- *Security state on page D1-1780.*
- *Virtualization on page D1-1782.*
- *Registers for instruction processing and exception handling on page D1-1785.*
- *Process state, PSTATE on page D1-1791.*
- *Program counter and stack pointer alignment on page D1-1793.*
- *Reset on page D1-1795.*
- *Exception entry on page D1-1799.*
- *Exception return on page D1-1815.*
- *The Exception level hierarchy on page D1-1819.*
- *Synchronous exception types, routing and priorities on page D1-1826.*
- *Asynchronous exception types, routing, masking and priorities on page D1-1834.*
- *Configurable instruction enables and disables, and trap controls on page D1-1842.*
- *System calls on page D1-1878.*
- *Mechanisms for entering a low-power state on page D1-1879.*
- *Self-hosted debug on page D1-1884.*
- *The Performance Monitors Extension on page D1-1886.*
- *Interprocessing on page D1-1887.*
- *The effect of implementation choices on the programmers' model on page D1-1899.*

## D1.1 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If EL $n$  is the Exception level, increased values of  $n$  indicate increased software execution privilege.
- Execution at EL0 is called *unprivileged execution*.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

### ———— Note ————

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

*The effect of implementation choices on the programmers' model on page D1-1899* shows some example implementations.

When executing in AArch64 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the *target Exception level* of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within a particular Security state. *The ARMv8-A security model on page D1-1780* describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then when execution is at EL3, the PE can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see *Chapter D4 The AArch64 Virtual Memory System Architecture*.

### D1.1.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

<b>EL0</b>	Applications.
<b>EL1</b>	OS kernel and associated functions that are typically described as <i>privileged</i> .
<b>EL2</b>	Hypervisor.
<b>EL3</b>	Secure monitor.

## D1.2 Exception terminology

The following subsections define the terms used when describing exceptions:

- [Terminology for taking an exception.](#)
- [Terminology for returning from an exception.](#)
- [Exception levels.](#)
- [Definition of a precise exception.](#)
- [Definitions of synchronous and asynchronous exceptions on page D1-1778.](#)

### D1.2.1 Terminology for taking an exception

An exception is *generated* when the PE first responds to an exceptional condition. The PE state at this time is the state the exception is *taken from*. The PE state immediately after taking the exception is the state the exception is *taken to*.

### D1.2.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception *returns from*. The PE state immediately after the execution of that instruction is the state the exception *returns to*.

### D1.2.3 Exception levels

An Exception level,  $EL_n$ , with a larger value of  $n$  than another Exception level, is described as being a *higher* Exception level than the other Exception level. For example,  $EL_3$  is a higher Exception level than  $EL_1$ .

An Exception level with a smaller value of  $n$  than another Exception level is described as being a *lower* Exception level than the other Exception level. For example,  $EL_0$  is a lower Exception level than  $EL_1$ .

An Exception level is described as:

- *Using AArch64* when execution in that Exception level is in the AArch64 Execution state.
- *Using AArch32* when execution in that Exception level is in the AArch32 Execution state.

### D1.2.4 Definition of a precise exception

An exception is described as *precise* when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the *SError interrupt*, all exceptions taken to AArch64 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch64 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by the instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address used by the instruction.

Also, for Data Aborts from load or store instructions executed in AArch64 state, where the Data Abort is taken synchronously:

- If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
- If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
- If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.

Examples of instructions that perform more than one single-copy atomic memory access are the AArch32 LDM and STM instructions and the AArch64 LDP and STP instructions.

———— **Note** —————

For the definition of a single-copy atomic access, see [Properties of single-copy atomic accesses on page B2-83](#).

---

## D1.2.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

For more information about synchronous exceptions, see [Synchronous exception types, routing and priorities on page D1-1826](#).

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about asynchronous exceptions, see [Asynchronous exception types, routing, masking and priorities on page D1-1834](#).

## D1.3 Execution state

The Execution states are:

**AArch64**      The 64-bit Execution state.

**AArch32**      The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

*Execution state on page A1-34* gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

---

**Note**

- *Typical Exception level usage model on page D1-1776* shows which Exception levels different software layers might typically use.
  - *The effect of implementation choices on the programmers' model on page D1-1899* gives information on supported configurations of Exception levels and Execution states.
- 

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. *Interprocessing on page D1-1887* describes this.

## D1.4 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

<b>Secure state</b>	When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.
<b>Non-secure state</b>	When in this state, the PE: <ul style="list-style-type: none"><li>• Can access only the Non-secure physical address space.</li><li>• Cannot access the Secure system control resources.</li></ul>

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see [About the Virtual Memory System Architecture \(VMSA\)](#) on page D4-2004.

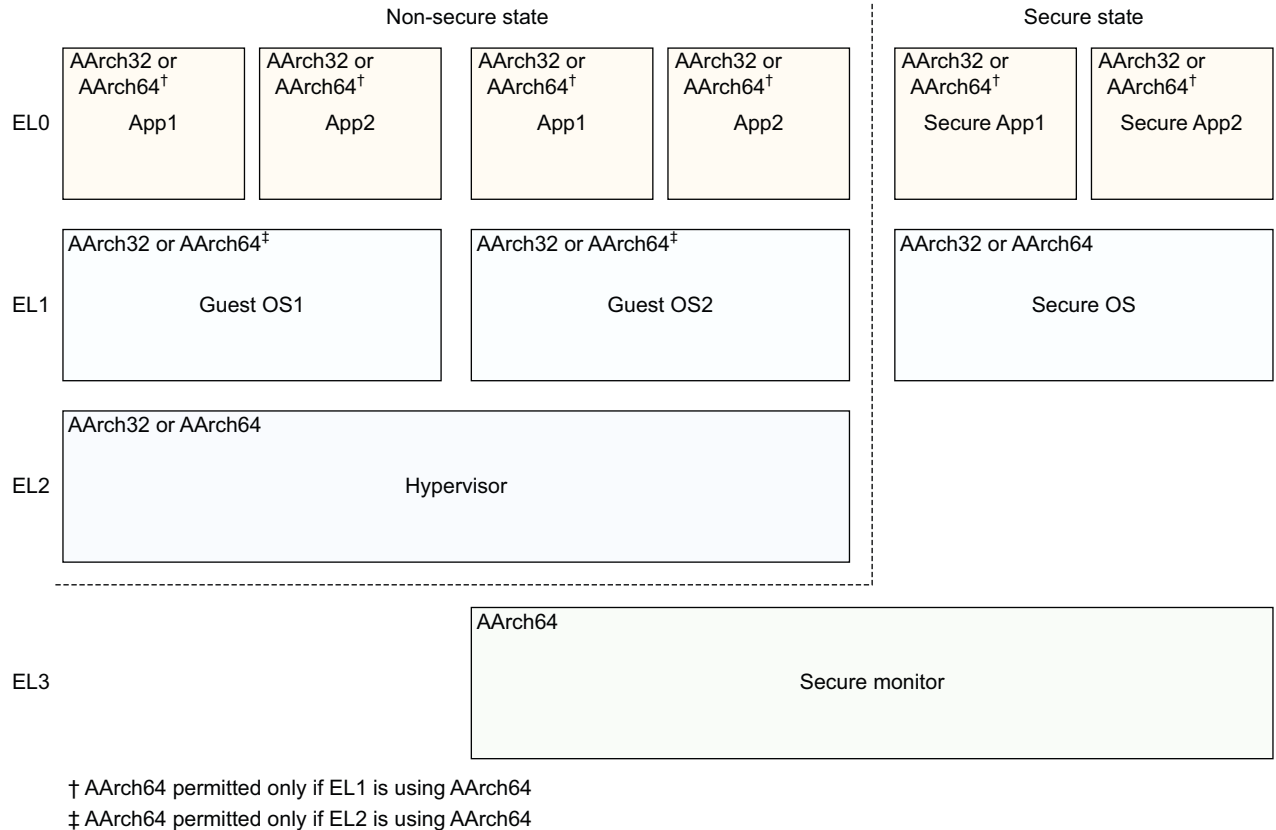

### D1.4.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If EL2 is implemented, it exists only in Non-secure state.
- If the implementation does not include EL3 it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
  - Non-secure state if the implementation includes EL2.

#### Security model when EL3 is using AArch64

[Figure D1-1 on page D1-1781](#) shows the security model when EL3 is using AArch64. The figure shows how instances of EL0 and EL1 are present in both Security states. It also shows the expected software usage of the different Exception levels.

**Figure D1-1 ARMv8-A security model when EL3 is using AArch64**

For an overview of the Security model when EL3 is using AArch32, see [Figure G1-1 on page G1-4316](#).

## D1.5 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between *virtual machines*. A virtual machine comprises Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems. A Guest OS runs on a virtual machine in Non-secure EL1.
- For each Guest operating system, applications, that run on the virtual machine of that Guest OS, usually in Non-secure EL0.

---

### Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

---

The hypervisor assigns a *virtual machine identifier* (**VMID**) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- *Trap* various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2. See [Configurable instruction enables and disables, and trap controls on page D1-1842](#).
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

ARMv8.1 introduces the Virtualization Host Extensions (VHE) that provide enhanced support for Type 2 hypervisors in Non-secure state. For more information, see [Virtualization Host Extensions on page D4-2098](#).

In Non-secure state, in an implementation that includes EL2:

- The implementation provides an independent translation regime for memory accesses from EL2, the EL2 translation regime. An implementation that includes [ARMv8.1-VHE](#) also supports an alternative EL2&0 translation regime.

---

### Note

An implementation that includes [ARMv8.1-VHE](#) can be configured so that the EL2&0 translation regime is used both for accesses from EL2 and for accesses from Non-secure EL0.

---

- For the EL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the *virtual address* (VA) to an *intermediate physical address* (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the *physical address* (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see [Chapter D4 The AArch64 Virtual Memory System Architecture](#).

### D1.5.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. [EL2 configurable controls on page D1-1851](#), describes these.
- All of the virtual interrupts:
  - Virtual SError.
  - Virtual IRQ.
  - Virtual FIQ.

Hypervisor call exceptions taken from EL3 are taken to EL3. Otherwise, Hypervisor call exceptions are taken from Non-secure state to EL2.

All virtual interrupts are always taken to Non-secure EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See [Virtual interrupts](#).

When a virtual interrupt is enabled, in Non-secure state its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3.

For more information, see [Asynchronous exception types, routing, masking and priorities on page D1-1834](#).

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information, see:
  - [Routing exceptions from Non-secure EL0 to EL2 on page D1-1827](#).
  - [Routing debug exceptions on page D2-1911](#).
- Provides mechanisms to trap Non-secure PE operations to EL2. See [EL2 configurable controls on page D1-1851](#).
 

When an operation is trapped to EL2, the hypervisor typically either:

  - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
  - Returns an error to the Guest OS.

#### Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in [Table D1-1](#).

**Table D1-1 The virtual interrupt**

Physical interrupt	Corresponding virtual interrupt
SError	Virtual SError
IRQ	Virtual IRQ
FIQ	Virtual FIQ

Software executing in EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. [Example D1-1](#) shows a usage model for virtual interrupts.

#### Example D1-1 Virtual interrupt usage model

A virtual interrupt usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.

2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
    - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
    - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
- 

A hypervisor can prevent Non-secure EL1 and Non-secure EL0 from distinguishing a virtual interrupt from a physical interrupt.

- [Asynchronous exception types, routing, masking and priorities on page D1-1834.](#)
- [Virtual interrupts on page D1-1839.](#)

## D1.6 Registers for instruction processing and exception handling

In the ARM architecture, registers fall into two main categories:

- Registers that provide system control or status reporting. These are described in [Chapter D7 AArch64 System Register Descriptions](#).
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions. This section introduces these registers, for execution in AArch64 state.

This section contains the following subsections:

- [The general purpose registers, R0-R30](#).
- [The stack pointer registers](#).
- [The SIMD and floating-point registers, V0-V31 on page D1-1786](#).
- [Saved Program Status Registers \(SPSRs\) on page D1-1786](#).
- [Exception Link Registers \(ELRs\) on page D1-1790](#).

### D1.6.1 The general purpose registers, R0-R30

The general purpose register bank is used when processing instructions in the base instruction set. It comprises 31 general purpose registers, R0-R30.

These registers can be accessed as 31 64-bit registers, X0-X30, or 31 32-bit registers, W0-W30. See [Register size on page C6-518](#).

For information on the format of these registers, see [Registers in AArch64 state on page B1-71](#).

### D1.6.2 The stack pointer registers

In AArch64 state, in addition to the general purpose registers, a dedicated stack pointer register is implemented for each implemented Exception level. The stack pointer registers are:

- [SP\\_EL0](#) and [SP\\_EL1](#).
- If the implementation includes EL2, [SP\\_EL2](#).
- If the implementation includes EL3, [SP\\_EL3](#).

#### ————— Note —————

The four stack pointer register names define an architecture state requirement for four registers. For information on how to access these registers, and access restrictions, see [Special-purpose registers on page C5-336](#).

For information on stack pointer alignment restrictions, see [SP alignment checking on page D1-1793](#).

### Stack pointer register selection

When executing at EL0, the PE uses the EL0 stack pointer, [SP\\_EL0](#).

When executing at any other Exception level, the PE can be configured to use either [SP\\_EL0](#) or the stack pointer for that Exception level, [SP\\_ELx](#).

By default, taking an exception selects the stack pointer for the target Exception level, [SP\\_ELx](#). For example, taking an exception to EL1 selects [SP\\_EL1](#). Software executing at the target Exception level can then choose to change the stack pointer to [SP\\_EL0](#) by updating [PSTATE.SP](#).

This applies even if taking the exception does not change the Exception level. For example, if the PE is executing at EL1 and the PE is using the [SP\\_EL0](#) stack pointer, then on taking an exception that targets EL1, the stack pointer changes to [SP\\_EL1](#).

The selected stack pointer can be indicated by a suffix to the Exception level:

- |          |  |
|----------|--|
| <b>t</b> | Indicates use of the <a href="#">SP_EL0</a> stack pointer. |
| <b>h</b> | Indicates use of the <a href="#">SP_ELx</a> stack pointer. |

---

**Note**

---

The t and h suffixes are based on the terminology of *thread* and *handler*, introduced in ARMv7-M.

---

Table D1-2 shows the set of stack pointer options.

**Table D1-2 AArch64 stack pointer options**

Exception level	AArch64 stack pointer options
EL0	EL0t
EL1	EL1t, EL1h
EL2	EL2t, EL2h
EL3	EL3t, EL3h

### D1.6.3 The SIMD and floating-point registers, V0-V31

The SIMD and floating-point instructions share a common bank of registers for floating-point, vector, and other SIMD-related scalar operations.

The SIMD and floating-point register bank comprises 32 quadword (128-bit) registers, V0-V31.

These registers can be accessed as:

- 32 doubleword (64-bit) registers, D0-D31.
- 32 word (32-bit) registers, S0-S31.
- 32 halfword (16-bit) registers, H0-H31.
- 32 byte (8-bit) registers, B0-B31.

For information on the format of these registers, see [Registers in AArch64 state on page B1-71](#).

### D1.6.4 Saved Program Status Registers (SPSRs)

The *Saved Program Status Registers* (SPSRs) are used to save PE state on taking exceptions.

In AArch64 state, there is an SPSR at each Exception level exceptions can be taken to, as follows:

- [SPSR\\_EL1](#), for exceptions taken to EL1 using AArch64.
- If EL2 is implemented, [SPSR\\_EL2](#), for exceptions taken to EL2 using AArch64.
- If EL3 is implemented, [SPSR\\_EL3](#), for exceptions taken to EL3 using AArch64.

---

**Note**

---

Exceptions cannot be taken to EL0.

---

When the PE takes an exception, the PE state is saved from PSTATE in the [SPSR](#) at the Exception level the exception is taken to. For example, if the PE takes an exception to EL1, the PE state is saved in [SPSR\\_EL1](#). For more information on [PSTATE](#), see [Process state, PSTATE on page D1-1791](#).

Saving the PE state means the exception handler can:

- On return from the exception, restore the PE state to the state stored in the [SPSR](#) at the Exception level the exception is returning from. For example, on returning from EL1, the PE state is restored to the state stored in [SPSR\\_EL1](#).
- Examine the value that PSTATE had when the exception was taken, for example to determine the Execution state and Exception level in which the instruction that caused an exception was executed.

### - Note

- All PSTATE fields are saved, including those which have no direct read and write access, and those that are meaningful only in AArch32 state.
- Those PSTATE fields that are meaningful only in AArch32 state are saved when an exception is taken from AArch32 state to AArch64 state.

The SPSRs are UNKNOWN on reset.

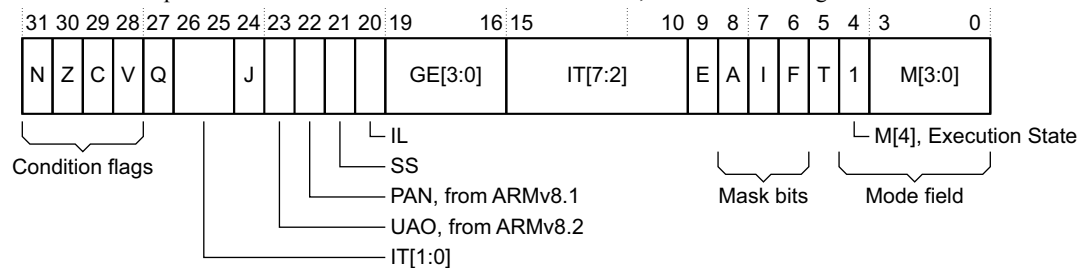

## SPSR format for exceptions taken to AArch64 state

Exceptions can be taken to AArch64 state from AArch64 state or AArch32 state:

- For an exception taken to AArch64 state from AArch64 state, the SPSR bit assignments are:

- For an exception taken to AArch64 state from AArch32 state, the SPSR bit assignments are:

The following list describes the bit assignments:

**N, Z, C, V, bits[31:28]**

Shows the values of the **PSTATE**.{N, Z, C, V} Condition flags immediately before the exception was taken.

**Bits[27:24], for exceptions taken from AArch64 state**

Reserved, RES0.

**Q, bit[27], for exceptions taken from AArch32 state**

Shows the value of `PSTATE.Q` immediately before the exception was taken.

**IT[1:0], bits[26:25], for exceptions taken from AArch32 state**

See *IT[7:2]* on page D1-1788.

**J, bit[24], for exceptions taken from AArch32 state**

Shows the value of **PSTATE.J** immediately before the exception was taken. This bit is RES0.

**UAO, bit[23], from ARMv8.2**

Shows the value of PSTATE.UAO immediately before the exception was taken.

This bit is RES0 in ARMv8.0 and in ARMv8.1 when ARMv8.2-UAO is not implemented.

**PAN, bit[22], from ARMv8.1**

Shows the value of `PSTATE.PAN` immediately before the exception was taken.

This bit is RES0 in ARMv8.0.

**SS, bit[21]** The Software Step bit.

[SPSR\\_ELx.SS](#) is used by a debugger to initiate a Software Step exception. The SS bit also indicates which software step state machine state the PE was in. See [Software Step exceptions on page D2-1956](#).

**IL, bit[20]** Illegal Execution state bit. Shows the value of [PSTATE.IL](#) immediately before the exception was taken. See [Illegal return events from AArch64 state on page D1-1816](#).

**Bits[19:10], for exceptions taken from AArch64 state**

Reserved, RES0.

**GE[3:0], bits [19:16], for exceptions taken from AArch32 state**

Shows the value of [PSTATE.GE](#) immediately before the exception was taken.

**IT[7:2], bits [15:10], for exceptions taken from AArch32 state**

With [IT\[1:0\] on page D1-1787](#), shows the value of [PSTATE.IT](#) before the exception was taken.

**D, bit[9], for exceptions taken from AArch64 state**

The debug exception mask bit. Shows the value of [PSTATE.D](#) immediately before the exception was taken. See [The PSTATE debug mask bit, D on page D1-1884](#).

**E, bit[9], for exceptions taken from AArch32 state**

Endianness of data accesses. Shows the value of [PSTATE.E](#) immediately before the exception was taken.

**A, I, F, bits[8:6]**

Shows the values of the [PSTATE](#).{A, I, F} exception mask bits immediately before the exception was taken:

**A, bit[8]** SError interrupt mask bit.

**I, bit[7]** IRQ mask bit.

**F, bit[6]** FIQ mask bit.

See [Asynchronous exception masking on page D1-1836](#).

**Bit[5], for exceptions taken from AArch64 state**

Reserved, RES0.

**T, bit[5], for exceptions taken from AArch32 state**

Shows the value of [PSTATE.T](#) immediately before the exception was taken.

**M[4:0], bits[4:0], for exceptions taken from AArch64 state**

———— **Note** —————

The name of this field is inherited from ARMv7, where the M field specified the *PE mode*.

**M[4]** The value of this is 0. M[4] encodes the value of [PSTATE.nRW](#), that indicates the Execution state from which the exception was taken.

**M[3:0]** Encodes the Exception level and the stack pointer register selection, as shown in [Table D1-3](#).

**Table D1-3 M[3:0] encodings, for exceptions taken from AArch64 state**

<b>M[3:0]<sup>a</sup></b>	<b>Exception level and stack pointer</b>
0b1101	EL3h
0b1100	EL3t
0b1001	EL2h
0b1000	EL2t
0b0101	EL1h
0b0100	EL1t
0b0000	EL0t

a. All M[3:0] encodings not shown in the table are reserved.

The M[3:0] encoding comprises:

**M[3:2]** Encodes the Exception level, 0-3.

**M[1]** Reserved, RES0. If set to 1 at the time of an exception return, then that exception return is treated as an Illegal Execution state exception return.

**M[0]** Selects the SP:

**0** [SP\\_EL0](#). Indicated by a t suffix on the Exception level.

**1** [SP\\_ELx](#), where *x* is the value of M[3:2]. Indicated by an h suffix on the Exception level.

See [Stack pointer register selection on page D1-1785](#).

#### **M[4:0], bits[4:0], for exceptions taken from AArch32 state**

The Mode field. Specifies the AArch32 PE mode.

**M[4]** The value of this is 1. M[4] encodes the value of [PSTATE.nRW](#), that indicates the Execution state from which the exception was taken.

**M[3:0]** Encodes the AArch32 PE mode that the PE was in immediately before the exception was taken, as shown in [Table D1-4](#).

**Table D1-4 M[3:0] encodings, for exceptions taken from AArch32 state**

<b>M[3:0]</b>	<b>AArch32 PE mode</b>
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

---

**Note**

---

In this description of SPSR:

- For exceptions taken from AArch64 state, [PSTATE](#) links to the AArch64 system level description.
  - For exceptions taken from AArch32 state, [PSTATE](#) links to the AArch32 system level description.
- 

SPSR bits:

- That are defined as RES0 on an exception taken from AArch32 state are ignored on any exception return to AArch32 state.
- That are defined as RES0 on an exception taken from AArch64 state are ignored on any exception return to AArch64 state.

### Pseudocode description of SPSR operations

The [SPSR\[\]](#) pseudocode function accesses the current SPSR, and is common to AArch32 and AArch64 operations.

The [SetPSTATEFromPSR\(\)](#) pseudocode function updates [PSTATE](#) from an SPSR.

## D1.6.5 Exception Link Registers (ELRs)

Exception Link Registers hold preferred exception return addresses.

Whenever the PE takes an exception, the preferred return address is saved in the ELR at the Exception level the exception is taken to. For example, whenever the PE takes an exception to EL1, the preferred return address is saved in [ELR\\_EL1](#).

On an exception return, the PC is restored to the address stored in the ELR. For example, on returning from EL1, the PC is restored to the address stored in [ELR\\_EL1](#).

AArch64 state provides an ELR for each Exception level exceptions can be taken to. The ELRs that AArch64 state provides are:

- [ELR\\_EL1](#), for exceptions taken to EL1.
- If EL2 is implemented, [ELR\\_EL2](#), for exceptions taken to EL2.
- If EL3 is implemented, [ELR\\_EL3](#), for exceptions taken to EL3.

On taking an exception from AArch32 state to AArch64 state, bits[63:32] of the ELR are set to zero.

The preferred return address depends on the nature of the exception. For more information, see [Preferred exception return address](#) on page D1-1799.

## D1.7 Process state, PSTATE

In the ARMv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:

- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type [ProcState](#). [ProcState](#) is defined in [Chapter J1 ARMv8 Pseudocode](#).

The PSTATE fields that are meaningful in AArch64 state are:

### The Condition flags

<b>N</b>	Negative Condition flag.
<b>Z</b>	Zero Condition flag.
<b>C</b>	Carry Condition flag.
<b>V</b>	Overflow Condition flag.

[Process state, PSTATE on page B1-73](#) gives more information about these flags.

### The Execution state controls

<b>SS</b>	Software Step bit, see <a href="#">Software Step exceptions on page D2-1956</a> . On a reset or taking an exception to AArch64 state, this bit is set to 0.
<b>IL</b>	Illegal Execution state bit, see <a href="#">The Illegal Execution state exception on page D1-1818</a> . On a reset or taking an exception to AArch64 state, this bit is set to 0.
<b>nRW</b>	Current Execution state, see <a href="#">Execution state on page D1-1779</a> . This bit is 0 when the current Execution state is AArch64. This bit is set to 0: <ul style="list-style-type: none"> <li>• On reset into an Exception level that is using AArch64.</li> <li>• On taking an exception to an Exception level that is using AArch64.</li> </ul>
<b>EL</b>	Current Exception level, see <a href="#">Exception levels on page D1-1776</a> . On a reset to AArch64 state, this field holds the encoding for the highest implemented Exception level.
<p style="text-align: center;"><b>Note</b></p> <p>The ARM architecture requires that a PE resets into the highest implemented Exception level.</p>	
<b>SP</b>	Stack pointer register selection bit, see <a href="#">Stack pointer register selection on page D1-1785</a> . On a reset or taking an exception to AArch64 state, this bit is set to 1, meaning that SP_ELx is selected.

### The exception mask bits

<b>D</b>	Debug exception mask bit, see <a href="#">The PSTATE debug mask bit, D on page D1-1884</a> . On a reset or taking an exception to AArch64 state, this bit is set to 1.						
<b>A, I, F</b>	Asynchronous exception mask bits: <table> <tr> <td><b>A</b></td><td>SError interrupt mask bit.</td></tr> <tr> <td><b>I</b></td><td>IRQ interrupt mask bit.</td></tr> <tr> <td><b>F</b></td><td>FIQ interrupt mask bit.</td></tr> </table> <p>See <a href="#">Asynchronous exception types, routing, masking and priorities on page D1-1834</a>. On a reset or taking an exception to AArch64 state, each of these bits is set to 1.</p>	<b>A</b>	SError interrupt mask bit.	<b>I</b>	IRQ interrupt mask bit.	<b>F</b>	FIQ interrupt mask bit.
<b>A</b>	SError interrupt mask bit.						
<b>I</b>	IRQ interrupt mask bit.						
<b>F</b>	FIQ interrupt mask bit.						

### Access control bits

<b>PAN</b>	<i>Privileged Access Never</i> (PAN) state bit. For more information, see <a href="#">About the PAN bit on page D4-2072</a> .
------------	---

**UAO** *User Access Override (UAO) bit. For more information, see [About the UAO bit on page D4-2072](#).*

### D1.7.1 Accessing PSTATE fields

In AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly read using the [MRS](#) instruction, and directly written using the [MSR \(register\)](#) instructions. [Table D1-5](#) shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state, when the PE is in AArch64 state. All other PSTATE fields do not have direct read and write access.

**Table D1-5 Accessing PSTATE fields using MRS and MSR (register)**

Special-purpose register	PSTATE fields
<a href="#">NZCV</a>	N, Z, C, V
<a href="#">DAIF</a>	D, A, I, F
<a href="#">CurrentEL</a>	EL
<a href="#">SPSel</a>	SP
<a href="#">PAN</a>	PAN
<b>UAO</b>	<b>UAO</b>

Software can also use the [MSR \(immediate\)](#) instruction to directly write to PSTATE.{D, A, I, F, SP, PAN, **UAO**}. [Table D1-6](#) shows the [MSR \(immediate\)](#) operands that can directly write to these PSTATE fields when the PE is in AArch64 state.

**Table D1-6 Accessing PSTATE.{D, A, I, F, SP} using MSR (immediate)**

Operand	PSTATE fields	Notes
DAIFSet	D, A, I, F	Directly sets any of the PSTATE.{D,A, I, F} bits to 1
DAIFClr	D, A, I, F	Directly clears any of the PSTATE.{D, A, I, F} bits to 0
SPSel	SP	Directly sets PSTATE.SP to either 1 or 0
PAN	PAN	Directly sets PSTATE.PAN to either 1 or 0
<b>UAO</b>	<b>UAO</b>	<b>Directly sets PSTATE.UAO to either 1 or 0</b>

PSTATE.{N, Z, C, V} can be accessed at EL0. Access to PSTATE.{D, A, I, F} at EL0 using AArch64 depends on [SCTLR\\_EL1.UMA](#), see [Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-1846](#). All other PSTATE access instructions can be executed at EL1 or higher and are UNDEFINED at EL0.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

### D1.7.2 The Saved Program Status Registers (SPSRs)

On taking an exception, PSTATE is preserved in the SPSR of the Exception level the exception is taken to. The SPSRs are described in [Saved Program Status Registers \(SPSRs\) on page D1-1786](#).

## D1.8 Program counter and stack pointer alignment

This section contains the following:

- [PC alignment checking](#).
- [SP alignment checking](#).

### D1.8.1 PC alignment checking

PC alignment checking generates a PC alignment fault exception associated with the instruction fetch if, in AArch64 state, there is an attempt to architecturally execute an instruction that was fetched with a misaligned PC. A misaligned PC is when bits[1:0] of the PC are not 0b00.

---

#### Note

As with Instruction Aborts, speculative fetching of an instruction does not generate an exception. An exception occurs only on an attempt to architecturally execute the instruction.

If an exception is generated as a result of an instruction fetch at EL0, it is taken to EL1, unless the exception occurs in Non-secure state and [HCR\\_EL2.TGE](#) bit is 1, when it is taken to EL2 instead. If an exception is generated as a result of an instruction fetch at any other Exception level, the Exception level is unchanged.

A PC misalignment sets the EC field in the *Exception Syndrome Register* (ESR) to 0x22, for the ESR associated with the target Exception level.

When the exception is taken to an Exception level using AArch64, the associated Exception Link Register holds the entire PC in its misaligned form, as does the [FAR\\_ELx](#) for the Exception level that the exception is taken to.

[Exception return and PC alignment on page D1-1816](#) gives more information on PC alignment checking associated with exception returns.

---

#### Note

A misalignment of the PC is a common indication of a serious error, for example software corruption of an address.

The pseudocode function [AArch64.CheckPCAlignment\(\)](#) performs PC alignment checking in AArch64 state. When necessary it calls [AArch64.PCAlignmentFault\(\)](#) to generate an exception.

### D1.8.2 SP alignment checking

A *misaligned stack pointer* is where bits[3:0] of the stack pointer are not 0b0000, when the stack pointer is used as the base address of the calculation, regardless of any offset applied by the instruction.

The PE can be configured so that if a load or store instruction uses a misaligned stack pointer, the PE generates an SP alignment fault exception on the attempt to execute the instruction. In this configuration, [CheckSPAlignment\(\)](#) performs the stack pointer check, and calls [AArch64.SPAlignmentFault\(\)](#) if a misaligned stack pointer is found.

---

#### Note

- As with Data Aborts, a speculative data access to memory using the stack pointer does not generate the exception. The exception occurs only on an attempt to architecturally execute the instruction.
- Prefetch memory abort instructions do not cause synchronous exceptions. See [Prefetch memory on page C3-171](#).

Stack pointer alignment checking is only performed in AArch64 state, and can be enabled for each Exception level as follows:

- [SCTLR\\_EL1](#).{SA0, SA} controls EL0 and EL1, respectively
- [SCTLR\\_EL2](#).SA controls EL2
- [SCTLR\\_EL3](#).SA controls EL3.

If an exception is generated as a result of a load or store at EL0, it is taken as an exception to EL1 unless the [HCR\\_EL2.TGE](#) bit is set in the Non-secure state, when it is taken to EL2. If an exception is generated as a result of a load or store at any other Exception level, the Exception level is unchanged.

A stack pointer misalignment sets the EC field to 0x26, in the ESR associated with the target Exception level. If memory alignment checking and stack pointer alignment checking are enabled, then an SP alignment fault has priority in setting the value of the EC field, in the ESR associated with the target Exception level.

The pseudocode function [CheckSPAlignment\(\)](#) performs the stack pointer alignment check. When necessary it calls [AArch64.SPAlignmentFault\(\)](#) to generate an exception.

## D1.9 Reset

The ARMv8-A architecture supports the following resets:

<b>Cold reset</b>	Resets all of the logic on which the PE executes, including the integrated debug functionality.  In some contexts, this logic is described as belonging to the <i>Cold reset domain</i> .
<b>Warm reset</b>	Resets the logic on which the PE executes, but does not reset the integrated debug functionality.  In some contexts, this logic is described as belonging to the <i>Warm reset domain</i> .

---

### Note

---

The ARMv8-A architecture also supports an *external debug reset*. See [External debug register resets on page H8-5572](#).

---

The difference between a Cold reset and a Warm reset is relevant only to the debug functionality and the [RMR\\_ELx](#) register, if an [RMR\\_ELx](#) register is implemented:

- A Warm reset permits debugging across a reset of the PE logic.
- Writing 1 to [RMR\\_ELx.RR](#) requests a Warm reset.

The mechanisms, other than [RMR\\_ELx.RR](#), to assert these resets are IMPLEMENTATION DEFINED. It is IMPLEMENTATION DEFINED whether:

- It is possible to independently assert an External Debug reset and a Cold reset.
- It is possible to assert a Warm reset, as opposed to asserting a Cold reset, other than by the use of [RMR\\_ELx.RR](#).

---

### Note

---

ARM recommends that:

- If separate Core and Debug power domains are implemented, as described in [Reset and debug on page H6-5545](#), then a Cold reset can be asserted independently of External Debug reset.
  - A Warm reset can be asserted to permit debugging across a reset of the PE logic.
- 

This means that an implementation can define other resets according to the requirements the implementation or system must fulfil. These other resets are outside the scope of the ARMv8-A architecture. However, they can be mapped onto the resets described here.

In the description that follows, the term *reset* is used in contexts where there is no difference between the effect of a Cold reset and the effect of a Warm reset.

On a reset, the PE enters the highest implemented Exception level.

If the highest implemented Exception level can use either Execution state, then:

- The implementation must include a *Reset Management Register* (RMR). Only one RMR is implemented. The RMR implemented is the RMR is associated with the highest Exception level.
- On a Cold reset, the Execution state entered is determined by a configuration input signal.
- On a Warm reset, the Execution state entered is determined by [RMR\\_ELx.AA64](#).

If the highest implemented Exception level is configured to use AArch64 state, then on reset:

- The stack pointer for the highest implemented Exception level, [SP\\_ELx](#), is selected.
- Execution starts at an IMPLEMENTATION DEFINED address, anywhere in the physical address range. The RVBAR associated with the highest implemented Exception level, [RVBAR\\_EL1](#), [RVBAR\\_EL2](#), or [RVBAR\\_EL3](#), holds this address.

The remainder of this section contains the following:

- [PE state on reset to AArch64 state](#).
- [Code sequence to use RMR\\_ELx.RR to request a Warm reset on page D1-1797](#).

For more information about reset see:

- [Behavior of caches at reset on page D3-1980](#).
- [TLB behavior at reset on page D4-2117](#).
- [Reset and debug on page H6-5545](#).

### D1.9.1 PE state on reset to AArch64 state

---

#### Note

See the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* for the reset requirements for GIC System registers.

---

Immediately after a reset, much of the PE state is UNKNOWN. However, some of the PE state is defined. If the PE resets to AArch64 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- Each of the [PSTATE](#).{D, A, I, F} interrupt masks is set to 1.
- The Software step control bit, [PSTATE](#).SS, is set to 0.
- The IL process state bit, [PSTATE](#).IL, is set to 0.
- All general-purpose, and SIMD and floating-point registers are UNKNOWN.
- The ELR and SPSR for each Exception level are UNKNOWN.
- The stack pointer register for each Exception level is UNKNOWN.
- Unless explicitly defined in this subsection, each System register at each Exception level is in an architecturally UNKNOWN state.
- The TLBs and caches are in an IMPLEMENTATION DEFINED state. This means that the TLBs, the caches, or both, might require invalidation using IMPLEMENTATION DEFINED invalidation sequences before the memory management system is enabled or Normal memory accesses are permitted to be Cacheable.

---

#### Note

- On reset, System register Cacheability control fields force all Normal memory accesses to be treated as Non-cacheable. This applies only for the translation regime used by the Exception level and Security state entered on reset. For information about these controls see [Enabling and disabling the caching of memory accesses on page D3-1978](#).
  - The implementation might include IMPLEMENTATION DEFINED resets. If it does, each of these resets might treat the cache and TLB state differently. The ARMv8-A architecture permits this.
  - Different IMPLEMENTATION DEFINED invalidation sequences might be required for different IMPLEMENTATION DEFINED resets.
  - In some implementations, the IMPLEMENTATION DEFINED invalidation sequence might be a NOP.
- 
- In the [SCTLR\\_ELx](#) for the highest implemented Exception level:
    - Each of the {M, C, I} bits is set to 0
    - The EE bit is set to an IMPLEMENTATION DEFINED value, typically defined by a configuration input.
  - If an RMR is implemented, [RMR\\_ELx](#).RR is set to 0. ELx in this context is the highest implemented Exception level.
  - The enables for the counter event stream are set to 0. This means that the following bits are set to 0:
    - [CNTKCTL\\_EL1](#).EVNTEN.
    - If the implementation includes EL2, [CNTHCTL\\_EL2](#).EVNTEN.

- [PMCR\\_EL0.E](#) is set to 0.

———— **Note** ————

This means the Performance Monitors cannot assert interrupts at reset.

- [OSDLR\\_EL1.DLK](#) bit is set to 0.
- Each of [MDCCINT\\_EL1](#).{TX, RX} is set to 0.
- [EDPRCR.CWRR](#) is set to 0.
- [EDPRSR.SR](#) is set to 1.
- If the implementation includes EL3, then each of [MDCR\\_EL3](#).{EPMAD, EDAD, SPME} is set to 0.
- If the implementation includes EL2, then [MDCR\\_EL2.HPMN](#) is set to the value of [PMCR\\_EL0.N](#).
- [EDES.R.OSUC](#) is set to 0, and [EDES](#).{SS, RC} are set to the values of [EDECR](#).{SS, RCE}.

———— **Note** ————

On an External debug reset, [EDECR](#).{SS, RCE} are set to 0.

Additionally, for a Cold reset into AArch64 state:

- If an RMR is implemented, [RMR\\_ELx.AA64](#) is set to 1. ELx in this context is the highest implemented Exception level.
- Each of [MDCCSR\\_EL0](#).{TXfull, RXfull} is set to 0.
- The [DBGPRCR\\_EL1.CORENPRDRQ](#) is set to the value of [EDPRCR.COREPURQ](#).  
An External Debug reset sets [EDPRCR.COREPURQ](#) to 0, see [External debug register resets on page H8-5572](#). If an External Debug reset and a Cold reset coincide, both [DBGPRCR\\_EL1.CORENPRDRQ](#) and [EDPRCR.COREPURQ](#) are reset to 0.
- The debug CLAIM bits are reset to 0.

———— **Note** ————

These are the bits that are set to 1 by writing to [DBGCLAIMSET\\_EL1.CLAIM](#), and cleared to 0 by writing to [DBGCLAIMCLR\\_EL1.CLAIM](#).

- Each of [EDSCR](#).{RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull} is set to 0.

———— **Note** ————

[MDCCSR\\_EL0](#).{RXfull, TXfull} reflect the values in [EDSCR](#).{RXfull, TXfull}.

- Each of [EDECCR](#).{NSE, SE} is set to 0.
- [OSLSR\\_EL1.OSLK](#) is set to 1.
- In the [EDPRSR](#):
  - The SPMAD, SDAD fields are set to 0.
  - The SPD field is set to 1.

## D1.9.2 Code sequence to use [RMR\\_ELx.RR](#) to request a Warm reset

The following assembler sequence uses [RMR\\_ELx.RR](#) to request a Warm reset:

```
; in addition, interrupts and debug requests for this PE should be disabled
; in the system before running this sequence to ensure the WFI suspends execution
MOV Wy, #3          ; for AArch64, #2 for AArch32; y is any register
```

```
    DSB                ; ensure all stores etc are complete
    MSR RMR_ELx, Wy    ; request the reset
    ISB                ; synchronise change to the RMR
Loop
    WFI                ; enter a quiescent state
    B Loop
```

### D1.9.3 Pseudocode description of reset

The `AArch64.TakeReset()` pseudocode function performs a reset into AArch64 state.

`AArch64.TakeReset()` calls the functions `AArch64.ResetGeneralRegisters()`, `AArch64.ResetSIMDFPRegisters()`, `AArch64.ResetSpecialRegisters()`, `AArch64.ResetSystemRegisters()`, and `ResetExternalDebugRegisters()`.

`AArch64.ResetSystemRegisters()` resets all System registers to their reset state as defined in the register descriptions in *PE state on reset to AArch64 state* on page D1-1796 and *Chapter D7 AArch64 System Register Descriptions*.

---

**Note**

The `AArch64.ResetSystemRegisters()` function only resets the System registers.

---

`ResetExternalDebugRegisters()` resets all external debug registers to their reset state as defined in the register descriptions in *Chapter H9 External Debug Register Descriptions*.

## D1.10 Exception entry

Exceptions are targeted at particular Exception levels. The Exception level that an exception targets is either programmed by software, or is determined by the nature of the exception.

Under no circumstances do exceptions cause execution to move to a lower Exception level.

If an asynchronous exception targets a lower Exception level, the exception is not taken and remains pending. See [Asynchronous exception routing on page D1-1834](#) and [Asynchronous exception masking on page D1-1836](#).

### ———— Note ————

The construction of the architecture means that usually, it is impossible for an exception to target a lower Exception level.

The Security state can only change on taking an exception if the exception is taken from Non-secure state to EL3.

### ———— Note ————

Taking an exception to EL3 from any Exception level has no effect on the value of the [SCR\\_EL3.NS](#) bit.

On taking an exception to AArch64 state:

- The PE state is saved in the [SPSR\\_ELx](#) at the Exception level the exception is taken to. See [Saved Program Status Registers \(SPSRs\) on page D1-1786](#).
- The preferred return address is saved in the [ELR\\_ELx](#) at the Exception level the exception is taken to. See [Exception Link Registers \(ELRs\) on page D1-1790](#).
- All of [PSTATE](#).{D, A, I, F} are set to 1. See [Process state, PSTATE on page D1-1791](#).
- [PSTATE.UAO](#) is set to 0. See [Process state, PSTATE on page D1-1791](#).
- If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the [ESR\\_ELx](#) at the Exception level the exception is taken to. See [Use of the ESR\\_EL1, ESR\\_EL2, and ESR\\_EL3 on page D1-1801](#).
- Execution moves to the target Exception level, and starts at the address defined by the exception vector. Which exception vector is used is also an indicator of whether the exception came from a lower Exception level or the current Exception level. See [Exception vectors on page D1-1800](#).
- The stack pointer register selected is the dedicated stack pointer register for the target Exception level. See [The stack pointer registers on page D1-1785](#).

The remainder of this section contains the following:

- [Preferred exception return address](#).
- [Exception vectors on page D1-1800](#).
- [Pseudocode description of exception entry to AArch64 state on page D1-1801](#).
- [Exception classes and the ESR\\_ELx syndrome registers on page D1-1801](#).
- [Summary of register updates on faults taken to an Exception level that is using AArch64 on page D1-1813](#).

### D1.10.1 Preferred exception return address

For an exception taken to an Exception level using AArch64, the Exception Link Register for that Exception level, [ELR\\_ELx](#), holds the preferred exception return address. The preferred exception return address depends on the nature of the exception, as follows:

- For asynchronous exceptions, it is the address of the instruction following the instruction boundary at which the interrupt occurs. Therefore, it is the address of the first instruction that did not execute, or did not complete execution, as a result of taking the interrupt.

- For synchronous exceptions other than system calls, it is the address of the instruction that generates the exception.
- For exception generating instructions, it is the address of the instruction that follows the exception generating instruction.

———— **Note** —————

If an exception generating instruction is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the exception generating instruction.

When an exception is taken from an Exception level using AArch32 to an Exception level using AArch64, the top 32 bits of the modified [ELR\\_ELx](#) are 0.

## D1.10.2 Exception vectors

When the PE takes an exception to an Exception level that is using AArch64, execution is forced to an address that is the *exception vector* for the exception. The exception vector exists in a *vector table* at the Exception level the exception is taken to.

A vector table occupies a number of consecutive word-aligned addresses in memory, starting at the *vector base address*.

Each Exception level has an associated *Vector Base Address Register* (VBAR), that defines the exception base address for the table at that Exception level.

For exceptions taken to AArch64 state, the vector table provides the following information:

- Whether the exception is one of the following:
  - Synchronous exception.
  - SError.
  - IRQ.
  - FIQ.
- Information about the Exception level that the exception came from, combined with information about the stack pointer in use, and the state of the register file.

[Table D1-7](#) shows this.

**Table D1-7 Vector offsets from vector table base address**

Exception taken from	Offset for exception type			
	Synchronous	IRQ or vIRQ	FIQ or vFIQ	SError or vSError
Current Exception level with <a href="#">SP_ELO</a> .	0x000	0x080	0x100	0x180
Current Exception level with <a href="#">SP_ELx</a> , x>0.	0x200	0x280	0x300	0x380
Lower Exception level, where the implemented level immediately lower than the target level is using AArch64. <sup>a</sup>	0x400	0x480	0x500	0x580
Lower Exception level, where the implemented level immediately lower than the target level is using AArch32. <sup>a</sup>	0x600	0x680	0x700	0x780

- a. For exceptions taken to EL3, if EL2 is implemented, the level immediately lower than the target level is EL2 if the exception was taken from Non-secure state, but EL1 if the exception was taken from Secure EL1 or EL0.

Reset is treated as a special vector for the highest implemented Exception level. This special vector uses an IMPLEMENTATION DEFINED address that is typically set either by a hardwired configuration of the PE or by configuration input signals. The `RVBAR_ELx` register contains this reset vector address, where  $x$  is the number of the highest implemented Exception level.

### D1.10.3 Pseudocode description of exception entry to AArch64 state

The `AArch64.TakeException()` pseudocode function describes the behavior when the PE takes an exception to an Exception level that is using AArch64. The `AArch64.ExceptionClass()` function determines the EC (Exception class) and IL (Instruction length) values required to report the exception, and `AArch64.ReportException()` reports the exception.

The pseudocode functions `AArch64.TakeException()`, `AArch64.ExceptionClass()`, and `AArch64.ReportException()` are described in [Chapter J1 ARMv8 Pseudocode](#).

### D1.10.4 Exception classes and the ESR\_ELx syndrome registers

If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the `ESR_ELx` at the Exception level the exception is taken to. The information saved is determined at the time the exception is taken, and is not changed as a result of the explicit synchronization that takes place at the start of taking the exception. See [Synchronization requirements for AArch64 System registers on page D7-2191](#). The following sections give more information:

- [Use of the ESR\\_EL1, ESR\\_EL2, and ESR\\_EL3.](#)
- [The EC used to report an exception routed to EL2 because HCR\\_EL2.TGE is 1 on page D1-1813.](#)

#### Use of the ESR\_EL1, ESR\_EL2, and ESR\_EL3

An `ESR_ELx` holds the syndrome information for an exception that is taken to AArch64 state.

#### ———— Note ————

This use of a syndrome is also the reporting model used for exceptions taken to Hyp mode when they are taken to EL2 using AArch32.

[Figure D1-2](#) shows the general format of the `ESR_ELx` registers.

**Figure D1-2 Overall format of the `ESR_ELx` registers**

The `ESR_ELx` fields are:

- |                        |  |
|------------------------|--|
| <b>EC, bits[31:26]</b> | The Exception class field, that indicates the cause of the exception.  |
| <b>IL, bit[25]</b>     | The Instruction length bit, for synchronous exceptions, that indicates whether a trapped instruction was a 16-bit or a 32-bit instruction.   |
| <b>ISS, bits[24:0]</b> | The Instruction specific syndrome field. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class. |

[ESR\\_ELx, Exception Syndrome Register \(ELx\) on page D7-2254](#) describes the register in full, including:

- Listing the valid EC field values.
- Describing the ISS for each Exception class.
- Giving a full description of the use of the IL field.

Table D1-8 shows the encoding of the [ESR\\_ELx.EC](#) field, the Exception class field. For each EC value, the table references a subsection of the [ESR\\_ELx](#) register definition that describes the ISS format, with links to descriptions of possible causes of the exception, for example the configuration required to enable a trap.

**Table D1-8 ESR\_ELx.EC field encoding**

EC	Exception class	From, state		To, Exception level			ISS encoding description
		AArch32 <sup>a</sup>	AArch64	EL1	EL2	EL3	
000000	Unknown reason	Yes	Yes	Yes	Yes	Yes	<a href="#">ISS encoding for exceptions with an unknown reason on page D7-2259</a>
000001	Trapped WFI or WFE instruction execution <sup>b</sup>	Yes	Yes	Yes	Yes	Yes	<a href="#">ISS encoding for an exception from a WFI or WFE instruction on page D7-2260</a>
000011	Trapped MCR or MRC access with (coproc==0b1111) <sup>b</sup> that is not reported using EC 0b000000	Yes	No	Yes	Yes	Yes <sup>c</sup>	<a href="#">ISS encoding for an exception from an MCR or MRC access on page D7-2262</a>
000100	Trapped MCRR or MRRC access with (coproc==0b1111) <sup>b</sup> that is not reported using EC 0b000000	Yes	No	Yes	Yes	Yes <sup>d</sup>	<a href="#">ISS encoding for an exception from an MCRR or MRRC access on page D7-2264</a>
000101	Trapped MCR or MRC access with (coproc==0b1110) <sup>b</sup>	Yes	No	Yes	Yes	Yes	<a href="#">ISS encoding for an exception from an MCR or MRC access on page D7-2262</a>
000110	Trapped LDC or STC access <sup>b</sup>	Yes	No	Yes	Yes	Yes	<a href="#">ISS encoding for an exception from an LDC or STC instruction on page D7-2266</a>
000111	Access to Advanced SIMD or floating-point functionality trapped by <a href="#">CPACR_EL1.FPEN</a> or <a href="#">CPTR_ELx.TFP</a> control <sup>e</sup>	Yes	Yes	Yes	Yes	Yes	<a href="#">ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTX_ELx.TFP on page D7-2268</a>

- See also *Reporting AArch32 synchronous exceptions taken to an Exception level using AArch64* on page D1-1813.
- Exceptions caused by configurable traps, enables, or disables.
- See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-1870.
- Only for MCRR or MRRC accesses to the **PMCCNTR\_EL0** or **PMCCNTR**.
- Excludes exceptions that are generated because the value of **HCR\_EL2.TGE** is 1, see *The EC used to report an exception routed to EL2 because HCR\_EL2.TGE is 1* on page D1-1813.
- Applies only to traps of accesses to **MVFR0**, **MVFR1**, **MVFR2**, or **FPSID**. Includes traps of VMRS accesses. Because the **MVFRn** registers are read-only and a VMSR access to the **FPSID** is ignored and not trapped, there are no MCR or VMSR accesses that can be trapped with this EC value.
- Only as a result of **HCR\_EL2.TGE**.
- Only as a result of **HCR\_EL2.TSC**.
- Used for MMU faults generated by instruction accesses, and for synchronous external aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
- Used for MMU faults generated by data accesses, Alignment faults other than SP alignment faults and PC alignment faults, and for synchronous external aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
- Only as a result of **HCR\_EL2.TGE** == 1 or **MDCR\_EL2.TDE** == 1.
- Only if the BRK instruction is executed in EL3. This is the only debug exception that can be taken to EL3 when EL3 is using AArch64.

### Reserved EC values

For EC values not shown in [Table D1-8 on page D1-1802](#):

- Unused EC values in the range 0b000000-0b101100 (0x00-0x2C) are reserved by ARM for future use for synchronous exceptions.
- Unused EC values in the range 0b101101-0b111111 (0x2D-0x3F) are reserved by ARM for future use, and might be used for synchronous or asynchronous exceptions.

### Exceptions with an unknown reason

These are the exceptions reported with an [ESR\\_ELx](#).EC value of 0b000000

This encoding reports an exception with an unknown reason.

When [ESR\\_ELx](#).EC returns a value of 0x00, all other fields of [ESR\\_ELx](#) are invalid, and defined as follows:

- IL is set to 1.
- ISS[24:0] is RES0.

An exception with an unknown reason occurs for the following reasons:

- The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.
  - Instruction encodings for instructions that are not implemented.
- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- An exception generated by any of the [SCTLR\\_EL1](#).{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by [HCR\\_EL2](#).HCD or [SCR\\_EL3](#).HCE.
  - An SMC instruction when disabled by [SCR\\_EL3](#).SMD.
  - An HLT instruction when disabled by [EDSCR](#).HDE.
- Attempted execution of an MSR or MRS to [SP\\_EL0](#) when the value of [SPSel.SP](#) is 0.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction in Non-secure state from EL0 when the value of [HCR\\_EL2](#).TGE is 1.
  - A DCPS2 instruction from EL1 or EL0 when the value of [SCR\\_EL3](#).NS is 0, or when EL2 is not implemented.
  - A DCPS3 instruction when the value of [EDSCR](#).SDD is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution of an SRS instruction using R13\_mon from Secure EL1. See [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1870](#).
- In Debug state when the value of [EDSCR](#).SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

- In AArch32 state, the attempted execution of an MRS (Banked register) or an MSR (Banked register) instruction to SPSR\_mon, SP\_mon, or LR\_mon.
- An exception that is taken to EL2 because the value of [HCR\\_EL2.TGE](#) is 1 that, if the value of [HCR\\_EL2.TGE](#) was 0 would have been reported with an [ESR\\_ELx.EC](#) value of 0x07.

#### **Exception from a WFI or WFE instruction, from AArch32 or AArch64 state**

This is the exception syndrome with EC value 0b000001.

This reports exceptions from WFI or WFE instructions executed in either Execution state that result from configurable traps, enables, or disables.

The returned syndrome indicates whether the trapped instruction was a WFI or a WFE. [ISS encoding for an exception from a WFI or WFE instruction on page D7-2260](#) describes the format of this syndrome.

The following sections describe configuration settings for generating these exceptions:

- [Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1845.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1861.](#)
- [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1870.](#)

#### **Exception from an MCR or MRC access from AArch32 state**

These are the exception syndromes with the following EC values:

- 0b000011, MRC or MCR access to a System register in the (coproc==0b1111) encoding space.
- 0b000101, MRC or MCR access to a System register in the (coproc==0b1110) encoding space.
- 0b001000, VMRS System register access.

These report exceptions from MRC, MCR, or VMRS instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of 0b000000.

The returned syndrome indicates whether the instruction was an MRC or an MCR, and the instruction arguments. [ISS encoding for an exception from an MCR or MRC access on page D7-2262](#) describes the format of this syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- [Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1849.](#)
- [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1850.](#)
- [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1853.](#)
- [Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions on page D1-1854.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1855.](#)
- [Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1856.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1857.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1858.](#)
- [Trapping to EL2 of Non-secure EL1 accesses to the CPACR\\_EL1 or CPACR on page D1-1862.](#)
- [General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1864.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1867.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1868.](#)
- [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1870.](#)

- [Trapping to EL3 of EL2 accesses to the CPTR\\_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR\\_EL1 or CPACR on page D1-1873.](#)
- [Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1877.](#)

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000101:

- [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1847.](#)
- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1848.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1858](#), for trapped accesses to the JIDR.
- [Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1863.](#)
- [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1865.](#)
- [Trapping System register accesses to powerdown debug registers to EL2 on page D1-1866.](#)
- [Trapping general System register accesses to debug registers to EL2 on page D1-1866.](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1874.](#)
- [Trapping System register accesses to powerdown debug registers to EL3 on page D1-1875.](#)
- [Trapping general System register accesses to debug registers to EL3 on page D1-1876.](#)

[Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1858](#) describes configuration settings for generating exceptions that are reported using EC value 0b001000.

#### **Exception from an MCRR or MRRC access from AArch32 state**

These are the exception syndromes with the following EC values:

- 0b000100, MRRC or MCRR access to a System register in the (coproc==0b1111) encoding space.
- 0b001100, MRRC access to a System register in the (coproc==0b1110) encoding space.

These report exceptions from MCRR or MRRC instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of 0x00.

The returned syndrome indicates whether the instruction was an MCRR or an MRRC, and the instruction arguments. [ISS encoding for an exception from an MCRR or MRRC access on page D7-2264](#) describes the format of this syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000100:

- [Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1849.](#)
- [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1850.](#)
- [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1853.](#)
- [General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1864.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1867.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1868.](#)
- [Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1877.](#)

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1847.](#)
- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1848.](#)

- [Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1863.](#)
- [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1865.](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1874.](#)
- [Trapping System register accesses to powerdown debug registers to EL3 on page D1-1875.](#)

### **Exception from an LDC or STC access to a System register**

This is the exception syndrome with EC value 0b000110.

This reports exceptions from LDC or STC instructions executed in AArch32 state that result from configurable traps, enables, or disables.

The returned syndrome indicates whether the instruction was an MCRR or an MRRC, and the instruction arguments. [ISS encoding for an exception from an LDC or STC instruction on page D7-2266](#) describes the format of this syndrome.

#### **———— Note ————**

The only architected uses of these instructions are:

- An STC to write to memory from [DBGDTRRXint](#).
- An LDC to read from memory to [DBGDTRTXint](#).

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000110:

- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1848.](#)
- [Trapping general System register accesses to debug registers to EL2 on page D1-1866](#)
- [Trapping general System register accesses to debug registers to EL3 on page D1-1876.](#)

### **Exception from an access to an Advanced SIMD or floating-point register, from either Execution state, resulting from CPACR\_EL1.FPEN or CPTR\_ELx.TFP**

This is the exception syndrome with EC value 0b000111.

#### **———— Note ————**

If [HCR\\_EL2.TGE](#) is 1, these exceptions are reported with EC value 0b000000 instead of 0b000111. [The EC used to report an exception routed to EL2 because HCR\\_EL2.TGE is 1 on page D1-1813](#) describes this.

It reports exceptions from accesses to the Advanced SIMD and floating-point register bank, or to SIMD and floating-point System registers, when [CPACR\\_EL1.FPEN](#) != 0b11 or [CPTR\\_ELx.TFP](#) == 1.

These are taken from either Execution state.

[ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR\\_EL1.FPEN or CPTR\\_ELx.TFP on page D7-2268](#) describes the format of the returned syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000111:

- [Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality on page D1-1848.](#)
- [General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers on page D1-1863](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1874.](#)

### **Exception from an Illegal Execution state, PC alignment fault, or SP alignment fault**

These are the exception syndromes with the following EC values:

- 0b001110, Illegal Execution state.
- 0b10010, PC alignment fault.
- 0b100110, SP alignment fault.

When [ESR\\_ELx.EC](#) returns one of these values, the ISS field does not return any syndrome information and the ISS field is RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. See [The Illegal Execution state exception on page D1-1818](#) and [PC alignment checking on page D1-1793](#). [SP alignment checking on page D1-1793](#) describes the configuration settings for generating SP alignment fault exceptions.

### **Exception from HVC or SVC instruction execution**

These are the exception syndromes with the following EC values:

- 0b010001, SVC instruction executed in AArch32 state.
- 0b010010, HVC instruction executed, when not disabled, in AArch32 state.
- 0b010101, SVC instruction executed in AArch64 state.
- 0b010110, HVC instruction executed, when not disabled, in AArch64 state.

The returned syndrome indicates the immediate value given as an instruction argument. [ISS encoding for an exception from HVC or SVC instruction execution on page D7-2270](#) describes the format of this syndrome.

#### **———— Note ————**

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its Condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

See [System calls on page D1-1878](#).

### **Exception from SMC instruction execution in AArch32 state**

This is the exception syndrome with EC value 0b010011.

This reports the exception from an SMC that is not disabled and is executed in AArch32 state.

[ISS encoding for an exception from SMC instruction execution in AArch32 state on page D7-2271](#) describes the format of this syndrome.

#### **———— Note ————**

[ISS encoding for an exception from SMC instruction execution in AArch32 state on page D7-2271](#) describes ISS[24:0] for each of the following cases:

- When an SMC instruction completes normally and generates an exception that is taken to EL3.
- When an SMC instruction is trapped to EL2 from Non-secure EL1 because [HCR\\_EL2.TSC](#) is set to 1.

[Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1858](#) describes the configuration settings for trapping SMC instructions to EL2.

### **Exception from SMC instruction execution in AArch64 state**

This is the exception syndrome with EC value 0b010111.

This reports the exception from an SMC that is not disabled and is executed in AArch64 state.

The returned syndrome indicates the immediate value given as an instruction argument. [ISS encoding for an exception from SMC instruction execution in AArch64 state on page D7-2272](#) describes the format of this syndrome.

#### **———— Note ————**

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from Non-secure EL1.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

[Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1858](#) describes the configuration settings for trapping SMC instructions to EL2.

### **Exception from MSR, MRS, or System instruction execution in AArch64 state**

This is the exception syndrome with the EC value 0b011000.

These report exceptions from MSR, MRS, or System instructions executed in AArch64 state that result from configurable traps, enables, or disables and are not reported using the EC codes of 0b000000, 0b000001, or 0b000111.

---

#### **Note**

[The System instruction class encoding space on page C5-312](#) identifies the System instructions referred to in this description.

---

The returned syndrome indicates whether the instruction was an MSR or an MRS, and the instruction arguments. [ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state on page D7-2273](#) describes the format of this syndrome.

For exceptions caused by System instructions, see [System on page C4-215](#) for the instruction arguments returned in the syndrome.

The following sections describe configuration settings for generating the exception that is reported using EC value 0b011000:

- In [EL1 configurable controls on page D1-1843](#):
  - [Traps to EL1 of EL0 execution of cache maintenance instructions on page D1-1844](#).
  - [Traps to EL1 of EL0 accesses to the CTR\\_EL0 on page D1-1845](#).
  - [Traps to EL1 of EL0 execution of DC ZVA instructions on page D1-1846](#).
  - [Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-1846](#).
  - [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1847](#).
  - [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1848](#).
  - [Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1849](#).
  - [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1850](#).
- In [EL2 configurable controls on page D1-1851](#):
  - [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1853](#).
  - [Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions on page D1-1854](#).
  - [Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions on page D1-1854](#).
  - [Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1855](#).
  - [Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1856](#).
  - [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1857](#).
  - [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1858](#).
  - [Trapping to EL2 of Non-secure EL1 accesses to the CPACR\\_EL1 or CPACR on page D1-1862](#).
  - [Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1863](#).
  - [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1865](#).
  - [Trapping System register accesses to powerdown debug registers to EL2 on page D1-1866](#).
  - [Trapping general System register accesses to debug registers to EL2 on page D1-1866](#).
  - [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1867](#).
  - [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1868](#).

- In *EL3 configurable controls* on page D1-1869:
  - *Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers* on page D1-1872.
  - *Trapping to EL3 of EL2 accesses to the CPTR\_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR\_EL1 or CPACR* on page D1-1873.
  - *Traps to EL3 of all System register accesses to the trace registers* on page D1-1874.
  - *Trapping System register accesses to powerdown debug registers to EL3* on page D1-1875.
  - *Trapping general System register accesses to debug registers to EL3* on page D1-1876.
  - *Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers* on page D1-1877.

### **Exception from an Instruction abort**

These are the exception syndromes with the following EC values:

- 0100000, for an Instruction abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- 0b100001, for an Instruction abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are used for MMU faults and synchronous external aborts, including synchronous parity or ECC errors, that are generated by instruction accesses. They are not used for Debug exceptions.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from an Instruction Abort* on page D7-2275 describes the format of this syndrome.

### **Exception from a Data abort**

These are the exception syndromes with the following EC values:

- 0b100100, for a Data abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- 0b100101, for a Data abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are used for the following exceptions if the exception is generated by a data access:

- MMU faults.
- Alignment faults other than SP alignment faults and PC alignment faults.
- Synchronous external aborts, including synchronous parity or ECC errors.

They are not used for Debug exceptions.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from a Data Abort* on page D7-2277 describes the format of this syndrome.

### **Floating-point exceptions**

These are the exception syndromes with the following EC values:

- 0b101000, trapped floating-point exception from AArch32.
- 0b101100, trapped floating-point exception from AArch64.

These Exception classes are supported only when the SIMD and floating-point implementation supports the trapping of floating-point exceptions. Otherwise, the 0x28 and 0x2C EC values are reserved. That is, these EC values are used to report the floating-point exceptions defined by IEEE 754, and the Input Denormal floating-point exception.

The returned syndrome identifies the trapped floating-point exception or exceptions. *ISS encoding for an exception from a trapped floating-point exception* on page D7-2281 describes the format of this syndrome.

In an implementation where the SIMD and floating-point implementation supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the [FPCR](#).{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the [FPSCR](#).{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

### **SError interrupt**

This is the exception syndrome with EC value 0b101111.

It is used to report the exception caused by an SError interrupt.

The returned syndrome is implementation specific. [ISS encoding for an SError interrupt on page D7-2283](#) describes the format of this syndrome. See also [Asynchronous exception types, routing, masking and priorities on page D1-1834](#).

### **Breakpoint exception or Vector Catch exception**

These are the exception syndromes with the following EC values:

- 0b110000, Breakpoint exception taken from a lower Exception level.
- 0b110001, Breakpoint exception taken without a change of Exception level.
- 0b111010, AArch32 Vector Catch exception.

The returned syndrome provides a fault code that indicates the cause of the exception. [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception on page D7-2285](#) describes the format of this syndrome.

For more information about generating these exceptions, see:

- [Breakpoint exceptions on page D2-1921](#).
- [Vector Catch exceptions on page D2-1955](#).

### **Watchpoint exception**

These are the exception syndromes with the following EC values:

- 0b110100, Watchpoint exception taken from a lower Exception level.
- 0b110101, Watchpoint exception taken without a change of Exception level.

The returned syndrome provides more information about the watchpoint, including a fault code that indicates the cause of the exception. [ISS encoding for an exception from a Watchpoint exception on page D7-2286](#) describes the format of this syndrome.

For more information about generating these exceptions, see [Watchpoint exceptions on page D2-1940](#).

### **Software Step exception**

These are the exception syndromes with the following EC values:

- 0b110010, Software Step exception taken from a lower Exception level.
- 0b110011, Software Step exception taken without a change of Exception level.

The returned syndrome provides more information about the exception, including a fault code that indicates its cause. [ISS encoding for an exception from a Software Step exception on page D7-2285](#) describes the format of this syndrome.

For more information about generating these exceptions, see [Software Step exceptions on page D2-1956](#).

### **Breakpoint Instruction exception**

These are the exception syndromes with the following EC values:

- 0b111000, BKPT instruction executed in AArch32 state.
- 0b111100, BRK instruction executed in AArch64 state.

The returned syndrome provides the comment that was provided as an argument to the Breakpoint Instruction. *ISS encoding for an exception from execution of a Breakpoint instruction on page D7-2287* describes the format of this syndrome.

For more information about generating these exceptions, see *Breakpoint Instruction exceptions on page D2-1919*.

### The EC used to report an exception routed to EL2 because HCR\_EL2.TGE is 1

When an exception is taken from EL0 to EL2 because the value of HCR\_EL2.TGE is 1, the exception is reported in ESR\_EL2. The EC value and corresponding ISS encoding used to report the exception in ESR\_EL2 depend on how an exception of the same class would be reported in ESR\_EL1 when the value of HCR\_EL2.{TGE, RW} is {0, 1}:

- If the exception would have been reported in ESR\_EL1 using the EC value 0x07 then it is reported in ESR\_EL2 using the EC value 0x00 and corresponding ISS encoding.
- Otherwise, the exception is reported in ESR\_EL2 using the EC value and ISS encoding that would have been used to report the exception ESR\_EL1.

### Reporting AArch32 synchronous exceptions taken to an Exception level using AArch64

Although possible exception causes are generally similar for AArch32 state and AArch64 state, AArch32 state has additional exception taxonomy that is not present in AArch64 state. The following sections described named AArch32 exceptions that can, in some contexts, be taken to an Exception level that is using AArch64:

- *Undefined Instruction exception on page G1-4376.*
- *Supervisor Call (SVC) exception on page G1-4380.*
- *Secure Monitor Call (SMC) exception on page G1-4382.*
- *Hypervisor Call (HVC) exception on page G1-4383.*
- *Prefetch Abort exception on page G1-4384.*
- *Data Abort exception on page G1-4387.*

When EL2 is using AArch64 and the value of HCR\_EL2.TGE is 1, these exceptions are routed to EL2, and reported in the ESR\_EL2. Table D1-9 shows how they are reported.

**Table D1-9 Syndrome reporting in ESR\_EL2 of HCR\_EL2 routing of exceptions**

AArch32 exception	Pseudocode	EC value used to report exception in ESR_ELx
Undefined Instruction	<code>AArch32.UndefinedFault()</code>	0x00, Exception for an unknown reason
Supervisor Call	<code>AArch32.CallSupervisor()</code>	0x11, Exception from SVC instruction executed in AArch32 state
Secure Monitor Call	See <i>SMC on page F5-3429</i> <sup>a</sup>	0x13, Exception from SMC instruction executed in AArch32 state
Hypervisor Call	<code>AArch32.CallHypervisor()</code>	0x12, Exception from HVC instruction executed in AArch32 state
Prefetch Abort	<code>AArch32.Abort()</code>	0x20, Exception from an Instruction abort at a lower Exception level
Data Abort	<code>AArch32.Abort()</code>	0x24, Exception from a Data abort at a lower Exception level

- a. The pseudocode in *Operation for all encodings on page F5-3430* identifies when the execution of an SMC instruction in AArch32 state generates an exception that is taken to EL3 using AArch64.

## D1.10.5 Summary of register updates on faults taken to an Exception level that is using AArch64

For all exceptions taken to an Exception level using AArch64 that are not listed in *Validity of FAR\_ELx on page D1-1814*, the FAR\_ELx for the Exception level the exception is taken to is UNKNOWN.

For all exceptions taken to EL2 using AArch64 that are not listed in *Validity of HPFAR\_EL2 on page D1-1814*, the HPFAR\_EL2 is UNKNOWN.

## Validity of FAR\_ELx

The faulting virtual address is saved in FAR\_ELx for the Exception level the exception is taken to if an exception is one of:

- An Instruction Abort exception.
- A Data Abort exception.
- A PC alignment fault exception.
- A Watchpoint exception.

The architecture permits that the FAR\_ELx is UNKNOWN for Synchronous External Aborts other than Synchronous External Aborts on Translation Table Walks. In this case, the ISS.FnV bit returned in ESR\_ELx indicates whether FAR\_ELx is valid.

If an exception is taken from an Exception level using AArch32 into an Exception level using AArch64, and that exception writes the FAR\_ELx at the Exception level the exception is taken to, the most significant 32 bits of the FAR\_ELx are all zero, unless both:

- The faulting address was generated by a load or store that sequentially incremented from address 0xFFFFFFFF. Such a load or store instruction is CONSTRAINED UNPREDICTABLE, see [Out of range virtual address on page K1-6105](#).
- The implementation treats such incrementing as setting bit[32] of the virtual address.

The FAR\_ELx for an Exception level is made UNKNOWN as a result of an exception return from that Exception level.

## Validity of HPFAR\_EL2

The faulting IPA is saved in HPFAR\_EL2 if the exception is an Instruction Abort or Data Abort taken to EL2 and the fault is one of:

- A Translation or Access Flag fault on a stage 2 translation.
- A stage 2 Address Size fault.
- A fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.

HPFAR\_EL2 is made UNKNOWN as a result of an exception return from EL2.

## D1.11 Exception return

In the ARMv8-A architecture, an exception return is always to the same Exception level or a lower Exception level. An exception return is used for:

- A return to a previously executing thread.
- Entry to a new execution thread. For example:
  - The initialization of a hypervisor by a Secure monitor.
  - The initialization of an operating system by a hypervisor.
  - Application entry from an operating system or hypervisor.

An exception return requires the simultaneous restoration of the PC and [PSTATE](#) to values that are consistent with the desired state of execution on returning from the exception.

In AArch64 state, an ERET instruction causes an exception return, see [ERET on page C6-622](#). On executing an ERET instruction at ELx:

- The PC is restored with the value held in [ELR\\_ELx](#).
- [PSTATE](#) is restored by using the contents of [SPSR\\_ELx](#).

[ELR\\_ELx](#) and [SPSR\\_ELx](#) are the [ELR\\_ELx](#) and [SPSR\\_ELx](#) at the Exception level the exception is returning from. The exception return makes this [ELR\\_ELx](#) and [SPSR\\_ELx](#) UNKNOWN.

See [Address tagging in AArch64 state on page D4-2006](#) for details of how tagged addresses are handled in an Exception return from an Exception level using AArch64 to an Exception level using AArch64.

### ————— Note —————

When returning from an Exception level using AArch64 to an Exception level using AArch32, the top 32 bits of the [ELR\\_ELx](#) are ignored.

An ERET instruction also:

- Sets the Event Register for the PE executing the ERET instruction. See [Mechanisms for entering a low-power state on page D1-1879](#).
- Resets the local Exclusives monitor for the PE executing the ERET instruction. This removes the risk of errors that might be caused when a path to an exception return fails to include a CLREX instruction.

### ————— Note —————

This behavior prevents self-hosted debug from software stepping through an LDREX/STREX pair. However, when self-hosted debug is using software step, it is highly probable that the Exclusives monitor state would be lost anyway, for other reasons. [Stepping code that uses Exclusives monitors on page D2-1968](#) describes this.

It is IMPLEMENTATION DEFINED whether the resetting of the local Exclusives monitor also resets the global Exclusives monitor.

The ERET instruction is UNDEFINED in EL0.

When returning from an Exception level using AArch64 to an Exception level using AArch32, the AArch32 context is restored. The ARMv8-A architecture defines the relationship between AArch64 state and AArch32 state, for:

- General-purpose registers.
- Special-purpose registers.
- System registers.

In an implementation that includes EL3, the Security state can only change on returning from an exception if the return is from EL3 to a lower Exception level.

The following sections give more information:

- [Exception return and PC alignment.](#)
- [Illegal return events from AArch64 state.](#)
- [Legal returns that set PSTATE.IL to 1 on page D1-1818.](#)
- [The Illegal Execution state exception on page D1-1818.](#)
- [Pseudocode description of exception return on page D1-1818.](#)

### D1.11.1 Exception return and PC alignment

When `SPSR_ELx.M[4] == 0`, indicating an Exception return to AArch64 state, the value of `ELR_ELx` is transferred to the PC. If this value is misaligned, subsequent execution results in a PC alignment fault exception.

When `SPSR_ELx.M[4] == 1`, indicating an Exception return to AArch32 state, the value of `ELR_ELx` is transferred to the PC except that, for a legal exception return:

- If `SPSR_ELx.T` is 0, `ELR_ELx[1:0]` are treated as being 0 for restoring the PC.
- If `SPSR_ELx.T` is 1, `ELR_ELx[0]` is treated as being 0 for restoring the PC.

This means that a PC alignment fault exception cannot occur following a legal exception return from AArch64 state to AArch32 state. However, where the Exception return with `SPSR_ELx.M[4] == 1` is an illegal exception return then it is IMPLEMENTATION DEFINED whether a misaligned value in `ELR_ELx` is aligned when it is restored to the PC.

#### ———— Note ————

In an implementation that forces the alignment of the PC value restored from `SPSR_ELx` on an illegal exception return with `SPSR_ELx.M[4] == 1`, if `SPSR_ELx.T == 1` the restored PC value might give rise to a PC alignment fault exception, because the PE remains in AArch64 state and only `ELR_ELx[0]` is treated as being 0 for restoring the PC.

For more information about the illegal exception return cases see [Illegal return events from AArch64 state.](#)

### D1.11.2 Illegal return events from AArch64 state

In this section:

**Return** In AArch64 state, refers to any of:

- Execution of an ERET instruction.
- Execution of a DRPS instruction in Debug state.
- Exit from Debug state.

**Saved process state value**

In AArch64 state, refers to any of:

- The value held in the `SPSR_ELx` for an ERET instruction.
- The value held in the `SPSR_ELx` for a DRPS instruction executed in Debug state.
- The value held in the `DSPSR_EL0` for a Debug state exit.

**Link address** In AArch64 state, refers to any of:

- The address held in `ELR_ELx` for an ERET instruction.
- The address held in `DLR_EL0` for a Debug state exit.

**Configured from reset**

Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling returns to a mode or state that is illegal. In AArch64 state, this can occur as the result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the Exception level being returned to is not implemented. For example a return to EL2 when EL2 is not implemented.

- A return to EL2 when EL3 is implemented and the value of the [SCR\\_EL3.NS](#) bit is 0.
- A return to Non-secure EL1 when EL2 is implemented and the value of the [HCR\\_EL2.TGE](#) bit is 1.
- A return where the value of the saved process state M[4] bit is 0, indicating a return to AArch64 state, and one of the following is true:
  - The M[1] bit is 1.
  - The M[3:0] bits are 0b0001.
  - The Exception level being returned to is using AArch32 state, as programmed by the [SCR\\_EL3.RW](#) or [HCR\\_EL2.RW](#) bits, or as configured from reset.
- A return where the value of the saved process state M[4] bit is 1, indicating a return to AArch32 state, and one of the following is true:
  - The M field value is not a valid AArch32 state PE mode. [Table D1-4 on page D1-1789](#) shows the valid M[3:0] values for AArch32 state PE modes. This includes the case where M[3:0] is 0b0000, indicating User mode, and EL0 does not support AArch32 state.
  - The Exception level being returned to is using AArch64 state as determined by the [SCR\\_EL3.RW](#) or [HCR\\_EL2.RW](#) field or the configuration from reset. This includes the case where the Exception level being returned to does not support AArch32 state.

**Note**

This means that, in an implementation that supports only AArch64 state, any attempt to return to AArch32 state is an illegal exception return.

- A Debug state exit from EL0 using AArch64 state, to EL0 using AArch32 state.

In these cases:

- [PSTATE.IL](#) is set to 1, to indicate an illegal return.
- [PSTATE](#).{EL, nRW, SP} are unchanged. This means the Exception level, Execution state, and stack pointer selection do not change as a result of the return.
- The following [PSTATE](#) bits are restored from the saved process state value:
  - The N, Z, C, V Condition flags.
  - The D, A, I, F exception mask bits.
- If the illegal return is an illegal exception return, the [PSTATE.SS](#) bit is handled as normal for a return. That is, the SS bit is handled in the same way as an exception return that is not an illegal exception return. See [Software Step exceptions on page D2-1956](#).  
In all these cases the [PSTATE.SS](#) bit is handled as it would be for a normal return, as described in [Entering the active-not-pending state on page D2-1958](#) and [Exiting Debug state on page H2-5471](#). DRPS never sets the SS bit. This is indicated in [Entering the active-not-pending state on page D2-1958](#).
- If the illegal return is not a DRPS instruction executed in Debug state, the PC is restored from the link address. However, if the value of the M[4] bit of the saved process state is 1, indicating a return to AArch32 state, then:
  - Bits[31:2] of the PC are restored from the link address.
  - Bits[63:32, 1:0] of the PC are UNKNOWN.

When the value of the [PSTATE.IL](#) bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See [The Illegal Execution state exception on page D1-1818](#).

All aspects of the illegal return, other than the effects described in this section, occur as they do for a legal return.

### D1.11.3 Legal returns that set PSTATE.IL to 1

In this section, *return*, *saved process state value*, and *link address* have the same meaning as defined in *Illegal return events from AArch64 state on page D1-1816*.

If the value of the IL bit in the saved process state is 1, then it is copied to PSTATE by a return, meaning that PSTATE.IL is set to 1. In this case, if the return is not an illegal return, and targets AArch32 state, then the PSTATE.{IT, T} bits are either:

- Set to 0.
- Copied from the saved process state value.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The PSTATE.{IT, T} bits are only valid in AArch32 state, see *Process state, PSTATE on page G1-4332*.

When the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See *The Illegal Execution state exception*.

### D1.11.4 The Illegal Execution state exception

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. In AArch64 state, the PSTATE.IL bit can be set to 1 by any of:

- An illegal return, as described in *Illegal return events from AArch64 state on page D1-1816*.
- A legal return that sets PSTATE.IL to 1, as described in *Legal returns that set PSTATE.IL to 1*.

An Illegal Execution state exception sets ESR\_ELx.EC for the target Exception level to the value of 0x0E.

On taking any exception to an Exception level that is using AArch64 state:

1. The value of the PSTATE.IL bit is copied into the SPSR\_ELx.IL bit for the Exception level to which the exception is taken.
2. The PSTATE.IL bit is cleared to 0.

#### ————— Note —————

This means that it is not possible for software to observe the value of PSTATE.IL.

For the priority of this exception class, see *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827*.

### D1.11.5 Pseudocode description of exception return

The AArch64.ExceptionReturn() pseudocode function transfers the return address to the PC, and restores PSTATE to its saved value by calling SetPSTATEFromPSR().

The IllegalExceptionReturn() function checks for an Illegal Execution state exception.

## D1.12 The Exception level hierarchy

The System registers provide controls that control PE behavior through the Exception level hierarchy.

If EL3 and EL2 are implemented, System registers at EL3 and EL2 provide controls that control the Execution state of lower Exception levels.

Table D1-10 shows the principal System registers.

**Table D1-10 Principal System registers**

EL3	EL2	EL1	Notes
<a href="#">SCTLR_EL3</a>	<a href="#">SCTLR_EL2</a>	<a href="#">SCTLR_EL1</a>	Controls execution for its own Exception level.
<a href="#">SCR_EL3</a>	<a href="#">HCR_EL2</a>	-	Controls execution at lower Exception levels.
-	<a href="#">HSTR_EL2</a>	-	Used only if at least one of EL1 and EL0 is using AArch32.

The prioritization of exceptions generated as a result of controls in these registers is described in *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827*.

The following sections describe the Exception level hierarchy:

- *The hierarchy of configuration and routing control.*
- *Control of SIMD, floating-point and trace functionality on page D1-1825.*
- *Control of IMPLEMENTATION DEFINED features on page D1-1825.*
- *Routing exceptions from Non-secure EL0 to EL2 on page D1-1827.*

### D1.12.1 The hierarchy of configuration and routing control

The following subsections give a summary of the controls available at each Exception level for controlling execution at that Exception level and all lower Exception levels:

- *Controls provided at EL3.*
- *Controls provided at EL2 on page D1-1821.*
- *Controls provided at EL1 on page D1-1823.*

For information on how the controls summarized in these subsections affect PE behavior, see the definitions of the control bits in the register descriptions.

#### Controls provided at EL3

See:

- *Controls provided by the [SCR\\_EL3](#).*
- *Controls provided by the [SCTLR\\_EL3](#) on page D1-1820.*
- *Controls provided by the [MDCR\\_EL3](#) on page D1-1820.*

#### Controls provided by the [SCR\\_EL3](#)

[SCR\\_EL3.NS](#) Determines the Security state of execution at EL1 and EL0.

[SCR\\_EL3.RW](#) Determines the Execution state of the next-lower Exception level.

[SCR\\_EL3](#).{EA, FIQ, IRQ}

Route:

**EA** Physical SError interrupts and synchronous External Aborts to EL3.

**FIQ** Physical FIQ interrupts to EL3.

**IRQ** Physical IRQ interrupts to EL3.

[SCR\\_EL3.SMD](#) Disables the Secure Monitor Call exception.

<b>SCR_EL3.HCE</b>	Enables the Hypervisor Call exception.
<b>SCR_EL3.ST</b>	Enables Secure EL1 access to the Secure timer.
<b>SCR_EL3.SIF</b>	Secure Instruction Fetch. When in Secure state, disables instruction fetches from Non-secure memory.
<b>SCR_EL3.TWI</b>	Trap Wait-For-Interrupt.
<b>SCR_EL3.TWE</b>	Trap Wait-For-Event.

#### **Controls provided by the SCTL3\_EL3**

**SCTL3\_EL3.{A, SA}** Enable alignment checking:

<b>A</b>	On data accesses from EL3.
<b>SA</b>	On the SP, when executing at EL3.

**SCTL3\_EL3.{M, C, I, WXN}**

Memory system control bits:

<b>M</b>	Enables EL3 stage 1 address translation.
<b>C</b>	When set to 0, makes data accesses to Normal memory from EL3, and Normal memory accesses to the EL3 translation tables, Non-cacheable.
<b>I</b>	When set to 0, makes instruction accesses to Normal memory from EL3 Non-cacheable.
<b>WXN</b>	For accesses from EL3, enables treating all writable memory regions as XN, execute-never.

**SCTL3\_EL3.EE** Defines the endianness of data accesses from EL3, including stage 1 translation table walks at EL3.

———— **Note** —————

Instruction fetches are always little-endian.

#### **Controls provided by the MDCR3\_EL3**

**MDCR3\_EL3.{EPMAD, EDAD}**

Enable external debugger accesses to:

<b>EPMAD</b>	Performance Monitors registers.
<b>EDAD</b>	Breakpoint and Watchpoint registers.

**MDCR3\_EL3.{SPME, SDD, SPD32}**

Secure debug controls:

<b>SPME</b>	Secure Performance Monitors enable. Enables event counting in Secure state.
<b>SDD</b>	Disables all debug exceptions taken from Secure state, if the <i>debug target Exception level</i> , EL <sub>D</sub> , is using AArch64.
<b>SPD32</b>	Enables debug exceptions from Secure EL1 using AArch32.

**MDCR3\_EL3.{TDOSA, TDA, TPM}**

These are trap controls, that control traps to EL3 of EL2, EL1, and EL0 accesses to the following:

<b>TDOSA</b>	The OS-related debug registers.
<b>TDA</b>	Those debug registers not included in the <a href="#">MDCR3_EL3.TDOSA</a> trap.
<b>TPM</b>	The Performance Monitors registers.

For EL1 and EL0, these traps apply to accesses from both Security states.

## Controls provided at EL2

EL2 is implemented only in Non-secure state, and its controls apply only to execution in Non-secure EL2, Non-secure EL1, and Non-secure EL0. See:

- [Controls provided by SCTLR\\_EL2.](#)
- [Controls provided by HCR\\_EL2.](#)
- [Controls provided by the HSTR\\_EL2 on page D1-1823.](#)
- [Controls provided by the MDCR\\_EL2 on page D1-1823.](#)

### Controls provided by SCTLR\_EL2

**SCTLR\_EL2.**{A, SA} Enable alignment checking:

<b>A</b>	On data accesses from EL2.
<b>SA</b>	On the SP, when executing at EL2.

**SCTLR\_EL2.**{M, C, I, WXN}

Memory system control bits:

<b>M</b>	Enables EL2 stage 1 address translation.
<b>C</b>	When set to 0, makes data accesses to Normal memory from EL2, and Normal memory accesses to the EL2 translation tables, Non-cacheable.
<b>I</b>	When set to 0, makes instruction accesses to Normal memory from EL2 Non-cacheable.
<b>WXN</b>	For accesses from EL2, enables treating all writable memory regions as XN, execute-never.

**SCTLR\_EL2.EE** Defines the endianness of data accesses from EL2, including stage 1 translation table walks at EL2.

Also defines the endianness of stage 2 translation table walks at Non-secure EL1 and EL0.

———— **Note** ————

Instruction fetches are always little-endian.

### Controls provided by HCR\_EL2

**HCR\_EL2.RW** Determines the Execution state of the next-lower Exception level.

**HCR\_EL2.**{AMO, IMO, FMO}

Route physical interrupts to EL2, and if the value of **HCR\_EL2.TGE** is 0, enable virtual interrupts:

<b>AMO</b>	Route physical SError interrupts to EL2 and enable virtual SError interrupts
<b>IMO</b>	Route physical IRQ interrupts to EL2 and enable virtual IRQ interrupts.
<b>FMO</b>	Route physical FIQ interrupts to EL2 and enable virtual FIQ interrupts.

———— **Note** ————

- If a physical interrupt is routed to both EL3 and EL2, routing to EL3 takes precedence over routing to EL2.
- When the value of **HCR\_EL2.TGE** is 0, the virtual interrupt enables apply regardless of whether the corresponding physical interrupt is routed to EL2 or to EL3.
- In ARMv8.0, when the value of **HCR\_EL2.TGE** is 1 the virtual interrupts are disabled.
- From ARMv8.1, when the value of **HCR\_EL2.TGE** is 1:
  - If **ARMv8.1-VHE** is not implemented, or if **HCR\_EL2.E2H** is 0, these fields behave as 1 for all purposes other than a direct read of the value of the fields.

- If [ARMv8.1-VHE](#) is implemented and [HCR\\_EL2.E2H](#) is 1, these fields behave as 0 for all purposes other than a direct read of the value of the fields.

#### [HCR\\_EL2](#).{VSE, VI, VF}

Cause a virtual interrupt to be pending:

<b>VSE</b>	Virtual SError interrupt.
<b>VI</b>	Virtual IRQ interrupt.
<b>VF</b>	Virtual FIQ interrupt.

[HCR\\_EL2.VM](#) Enable bit for Non-secure EL1&0 stage 2 address translations.

#### [HCR\\_EL2](#).{SWIO, PTW, FB, BSU, DC, CD, ID}

Controls for memory system behavior for accesses made from Non-secure EL1 and EL0:

<b>SWIO</b>	Set/Way Invalidate Override.
<b>PTW</b>	Protect Table Walk.
<b>FB</b>	Force broadcast of TLB and instruction cache maintenance instructions.
<b>BSU</b>	Barrier Shareability Upgrade.
<b>DC</b>	Default Cacheability control for the EL1&0 translation regime.
<b>CD</b>	For the Non-secure EL1&0 translation regime, when set to 1, forces stage 2 translation table walks to Normal memory, and stage 2 translations for data accesses to Normal memory, to be Non-cacheable.
<b>ID</b>	For the Non-secure EL1&0 translation regime, when set to 1, forces stage 2 translations for instruction accesses to Normal memory be Non-cacheable.

[HCR\\_EL2.HCD](#) Hypervisor Call Disable.

#### **Note**

If an implementation includes EL3, this bit is RES0.

#### [HCR\\_EL2](#).{TRVM, TDZ, TVM, TTLB, TPU, TPC, TSW, TACR, TIDCP, TSC, TID1, TID2, TID3, TWE, TWI}

Trap operations performed at Non-secure EL1 or EL0 to EL2, as follows:

<b>TRVM</b>	Trap Read of Virtual Memory controls.
<b>TDZ</b>	Trap Data Cache Zero.
<b>TVM</b>	Trap Virtual Memory controls.
<b>TTLB</b>	Trap TLB maintenance instructions.
<b>TPU</b>	Trap cache maintenance to the Point of Unification instructions.
<b>TPC</b>	Trap data cache maintenance to the Point of Coherency instructions.
<b>TSW</b>	Trap data cache maintenance by Set/Way instructions.
<b>TACR</b>	Trap Auxiliary Control Register accesses.
<b>TIDCP</b>	Trap Implementation-Dependent functionality.
<b>TSC</b>	Trap Secure Monitor Call.
<b>TID0</b>	Trap ID Group 0 register accesses.
<b>TID1</b>	Trap ID Group 1 register accesses.
<b>TID2</b>	Trap ID Group 2 register accesses.
<b>TID3</b>	Trap ID Group 3 register accesses.
<b>TWI</b>	Trap Wait-For-Interrupt.
<b>TWE</b>	Trap Wait-For-Event.

**Note**

There are no AArch64 System registers in ID Group 0, therefore the TID0 trap is only relevant when Non-secure EL1 is using AArch32.

**HCR\_EL2.TGE** Trap General Exceptions.

**Controls provided by the HSTR\_EL2**

When EL2 is using AArch64 and at least one of Non-secure EL1 or EL0 is using AArch32, **HSTR\_EL2** provides the following trap of Non-secure AArch32 operation to EL2:

**HSTR\_EL2.Tn, for values of  $n$  in the set {0-3, 5-13, 15}**

Trap accesses to System registers in the AArch32 (coproc==0b1111) encoding space, by the value of  $n$ , where  $n$  is:

- The numeric value of the CRn argument used when accessing the register using an MCR or MRC instruction.
- The numeric value of the CRm argument used when accessing the register using an MCRR or MRRC instruction.

**Controls provided by the MDCR\_EL2**

**MDCR\_EL2.{TDRA, TDOSA, TDA}**

Trap controls, that control traps to EL2 of Non-secure EL1 and EL0 System register accesses to the following:

**TDRA** The Debug ROM registers.

**TDOSA** The OS-related debug registers.

**TDA** Those debug registers not included in either of the **MDCR\_EL2.TDRA** or **MDCR\_EL2.TDOSA** traps.

**MDCR\_EL2.TDE** Routes all debug exceptions taken from Non-secure EL1 and EL0 to EL2.

**MDCR\_EL2.{TPM, TPMCR}**

These are trap controls, that control traps to EL2 of Non-secure EL1 and EL0 accesses to the following registers:

**TPM** All Performance Monitors registers.

**TPMCR** The Performance Monitors Control Registers.

**MDCR\_EL2.HPMN** Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 and EL0.

**Controls provided at EL1**

See:

- [Controls provided by the SCTL\\_EL1](#).
- [Controls provided by the MDSCR\\_EL1](#) on page D1-1824.

**Controls provided by the SCTL\_EL1**

**SCTL\_EL1.{A, SA}** Enable alignment checking:

**A** On data accesses from EL1 and EL0.

**SA** On the SP, when executing at EL1.

**SCTL\_EL1.SA0** Enable alignment checking on the SP when executing at EL0.

#### SCTLR\_EL1.{M, C, I, WXN}

Memory system control bits:

- M** Enables EL1&0 stage 1 address translation.
- C** When set to 0, makes data accesses to Normal memory from EL0 and EL1, and Normal memory accesses to the EL1&0 stage 1 translation tables, Non-cacheable.
- I** When set to 0, makes instruction accesses to Normal memory from EL1 and EL0 Non-cacheable.
- WXN** For accesses from EL1 and EL0, enables treating all writable memory regions as XN, execute-never.

**SCTLR\_EL1.EE** Defines the endianness of data accesses from EL1, including stage 1 translation table walks at EL1 and EL0.

#### ———— **Note** ————

Instruction fetches are always little-endian.

**SCTLR\_EL1.E0E** EL0 Endianness. Defines the endianness used for explicit data accesses made from EL0.

#### SCTLR\_EL1.{UCI, UCT, DZE, nTWI, nTWE}

Trap enables:

- UCI** Unprivileged Cache maintenance Instruction enable.
- UCT** Unprivileged Cache Type access enable.
- DZE** Data cache Zero Enable.
- nTWI** Not Trap Wait-For-Interrupt.
- nTWE** Not Trap Wait-For-Event.

**SCTLR\_EL1.UMA** Unprivileged Mask Access.

#### SCTLR\_EL1.{SED, ITD, CP15BEN}

These bits control the use, at EL0, of AArch32 functionality that is deprecated, or OPTIONAL and deprecated:

- SED** Disables use of the SETEND instruction.
- ITD** If supported, disables some uses of the IT instruction. The register field description identifies the uses that are disabled.
- CP15BEN** If supported, enables use of the [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) memory barrier instructions.

The deprecated uses of the IT instruction, and use of the [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) instructions, are deprecated for performance reasons. Implementation of the ITD and CP15BEN controls is optional, and if a control is not implemented then the associated AArch32 functionality cannot be disabled.

### Controls provided by the MDSCR\_EL1

#### MDSCR\_EL1.{MDE, SS}

Enable controls for the debug exceptions:

- MDE** Enables Breakpoint exceptions, Watchpoint exceptions, and Vector Catch exceptions.
- SS** Enables Software Step exceptions.

There is no enable control for Breakpoint Instruction exceptions. Breakpoint Instruction exceptions are always enabled.

**MDSCR\_EL1.KDE** Enables debug exceptions from EL<sub>D</sub> when EL<sub>D</sub> is using AArch64.

**MDSCR\_EL1.TDCC** Enables a trap to EL1 of EL0 accesses to the Debug Communications Channel registers.

## D1.12.2 Control of SIMD, floating-point and trace functionality

In addition to the controls described in *The hierarchy of configuration and routing control* on page D1-1819, the following registers provide a hierarchy of control of access to SIMD and floating-point functionality, and to trace functionality that is accessible using the System registers:

**CPTR\_EL3** Traps operation at lower Exception levels to EL3, if the operation is not trapped to EL2 by **CPTR\_EL2** and is not trapped to EL1 by **CPACR\_EL1**.

**CPTR\_EL2** Traps operation in Non-secure EL1 or EL0 to EL2, if the operation is not trapped to EL1 by **CPACR\_EL1**. **CPTR\_EL2**.{TTA, TFP} also trap operation in EL2.

The trap bits in the **CPTR\_EL3** and **CPTR\_EL2** are as follows:

**TCPAC** Traps accesses to the registers that control access to SIMD, floating-point, and trace functionality.

**TTA** Traps any System register access to trace functionality, unless that access is otherwise trapped to a lower Exception level.

**TFP** Traps any execution of an instruction that uses the SIMD and floating-point register bank, unless that access is otherwise trapped to a lower Exception level.

**CPACR\_EL1** Traps operation from EL1 or EL0 to EL1. Traps set in the **CPACR\_EL1** take precedence over any traps set in the **CPTR\_EL2** or **CPTR\_EL3**. The trap fields are as follows:

**TTA** Traps to EL1 any System register access from EL0 or EL1 to trace functionality.

**FPEN** Traps to EL1 execution of instructions that uses the SIMD and floating-point register bank.

## D1.12.3 Control of IMPLEMENTATION DEFINED features

*The hierarchy of configuration and routing control* on page D1-1819 and *Control of SIMD, floating-point and trace functionality* describe the controls of the trapping of architecturally-defined functionality. However, the architecture also defines registers that can be used to provide IMPLEMENTATION DEFINED traps of IMPLEMENTATION DEFINED functionality to the different Exception levels. Table D1-11 shows these control registers, for AArch64 state controls.

**Table D1-11 Control of traps of IMPLEMENTATION DEFINED functionality**

Traps to EL3	Traps to EL2	Traps to EL1	Notes
<b>ACTLR_EL3</b>	<b>ACTLR_EL2</b>	<b>ACTLR_EL1</b>	Registers also provide IMPLEMENTATION DEFINED configuration controls for the appropriate Exception level.
-	<b>HACR_EL2</b>	-	Provides traps of IMPLEMENTATION DEFINED Non-secure EL1 and EL0 functionality to EL2.

## D1.13 Synchronous exception types, routing and priorities

Synchronous exceptions are:

- Any exception generated by attempting to execute an instruction that is UNDEFINED, including:
  - Attempts to execute instructions at an inappropriate Exception level.
  - Attempts to execute instructions when they are disabled.
  - Attempts to execute instruction bit patterns that have not been allocated.
- Illegal Execution state exceptions. These are caused by attempts to execute an instruction when the value of [PSTATE.IL](#) is 1, see [Illegal return events from AArch64 state on page D1-1816](#).
- Exceptions caused by the use of a misaligned SP.
- Exceptions caused by attempting to execute an instruction with a misaligned PC.
- Exceptions caused by the exception-generating instructions SVC, HVC, or SMC.
- Traps on attempts to execute instructions that the System registers define as instructions that are trapped to a higher Exception level. See [Configurable instruction enables and disables, and trap controls on page D1-1842](#).
- Instruction Aborts generated by the memory address translation system that are associated with attempts to execute instructions from areas of memory that generate faults.
- Data Aborts generated by the memory address translation system that are associated with attempts to read or write memory that generate faults.
- Data Aborts caused by a misaligned address.
- All of the debug exceptions:
  - Breakpoint Instruction exceptions.
  - Breakpoint exceptions.
  - Watchpoint exceptions.
  - Vector Catch exceptions.
  - Software Step exceptions.
- In an implementation that supports the trapping of floating-point exceptions, exceptions caused by trapped IEEE floating-point exceptions, see [Floating-point exceptions and exception traps on page D1-1831](#).
- In some implementations, External aborts. External aborts are failed memory accesses, and include accesses to those parts of the memory system that occur during the address translation. The ARMv8 architecture permits, but does not require, implementations to treat such exceptions synchronously. See [External aborts on page D3-1997](#).

This remainder of this section contains the following:

- [Routing exceptions from Non-secure EL0 to EL2 on page D1-1827](#).
- [Routing debug exceptions in Non-secure state to EL2 on page D1-1827](#).
- [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#).
- [Effect of Data Aborts on page D1-1830](#).
- [Floating-point exceptions and exception traps on page D1-1831](#).

### D1.13.1 Routing exceptions from Non-secure EL0 to EL2

When the value of [HCR\\_EL2.TGE](#) is 1, any exception taken from Non-secure EL0 that would otherwise be taken to Non-secure EL1 is, instead, routed to EL2. This means that an application can execute at Non-secure EL0 without using any functionality at Non-secure EL1.

---

**Note**

- When EL2 is using AArch64, the [HCR\\_EL2.TGE](#) control applies regardless of whether Non-secure EL0 is using AArch32 or AArch64.
- Implementations typically use the following Exception level and software hierarchy in Non-secure state:  
**EL2** Hypervisor.  
**EL1** Operating system.  
**EL0** Application.

In such an implementation, setting [HCR\\_EL2.TGE](#) to 1 means that an application can run at Non-secure EL0 under the direct control of a hypervisor executing at EL2, with no operating system involvement.

---

### D1.13.2 Routing debug exceptions in Non-secure state to EL2

When the value of [MDCR\\_EL2.TDE](#) is 1, debug exceptions taken from Non-secure state are routed to EL2. For more information see [Routing debug exceptions on page D2-1911](#).

When the value of [MDCR\\_EL2.TDE](#) is 1, each of the [MDCR\\_EL2](#).{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than direct reads of the [MDCR\\_EL2](#).

### D1.13.3 Synchronous exception prioritization for exceptions taken to AArch64

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. For exceptions taken to an Exception level that is using AArch64, these are prioritized as follows, where 1 is the highest priority.

---

**Note**

The priority numbering in this list only shows the relative priorities of exceptions taken to an Exception level that is using AArch64. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#).

---

1. Software Step exceptions. See [Software Step exceptions on page D2-1956](#).
2. PC alignment fault exceptions. See [PC alignment checking on page D1-1793](#).
3. Instruction Abort exceptions. See [Exception from an Instruction abort on page D1-1811](#) and [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-2110](#).
4. Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
  - [Breakpoint exceptions on page D2-1921](#).
  - [Vector Catch exceptions on page D2-1955](#).

Vector Catch exceptions are only taken from AArch32 state.

---

**Note**

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#). This means that it is outside the scope of the description of this section.

---

5. Illegal Execution state exceptions. See [Illegal return events from AArch64 state on page D1-1816](#).

6. Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
  - [HSTR\\_EL2.Tn](#).
  - [HCR\\_EL2.TIDCP](#).

**Note**

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are [HSTR.Tn](#) and [HCR.TIDCP](#).

7. Exceptions that occur as a result of attempting to execute an instruction that is UNDEFINED for one or more of the following reasons:
  - Attempting to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
  - Attempting to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
  - Debug state execution of an instruction encoding that is unallocated in Debug state.
  - Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
  - Execution of an HVC instruction, when HVC instructions are disabled by [SCR\\_EL3.HCE](#) or [HCR\\_EL2.HCD](#).
  - Execution of an MSR or MRS instruction to [SP\\_EL0](#) when the value of [SPSel](#) is 0.
  - Execution of an HLT instruction when HLT instructions are disabled by [EDSCR.HDE](#).
  - In Debug state:
    - Execution of a DCP51 instruction in Non-secure EL0 when [HCR\\_EL2.TGE](#) is 1.
    - Execution of a DCP52 instruction in EL1 or EL0 when [SCR\\_EL3.NS](#) is 0 or when EL2 is not implemented.
    - Execution of a DCP53 instruction when [EDSCR.SDD](#) is 1 or when EL3 is not implemented.
    - When the value of [EDSCR.SDD](#) is 1, execution in EL2, EL1, or EL0 of an instruction that is trapped to EL3.
  - When executing in AArch32 state, execution of an instruction that is UNDEFINED as a result of any of:
    - Being in an IT block when [SCTLR\\_EL1.ITD](#) is 1.
    - Executing a SETEND instruction executed [SCTLR\\_EL1.SED](#).
    - Executing a [CP15DMB](#), [CP15DSB](#), or [CP15ISB](#) barrier instruction when [SCTLR\\_EL1.CP15BEN](#) is 0.

**Note**

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are [SCTLR](#).{ITD, SED, CP15BEN}, with additional controls [HSCTLR](#).{ITD, SED, CP15BEN}.

See [Disabling or enabling EL0 use of AArch32 deprecated functionality on page D1-1847](#)

- When executing in AArch32 state, execution of an instruction that is UNDEFINED because at least one of [FPCR](#).{Stride, Len} is nonzero, when programming these bits to nonzero values is supported. See [Floating-point exception traps on page G1-4416](#).

**Note**

- This case applies only when EL0 is using AArch32 and EL1 is using AArch64. The exception generated by the attempted execution at EL0 of the UNDEFINED instruction is taken to EL1 using AArch64.
- When EL1 is using AArch32, the corresponding controls are [FPSCR](#).{Stride, Len}, and any exception generated by the attempted execution at EL0 or EL1 of an instruction that is UNDEFINED because of a nonzero {Stride, Len} value is taken to EL1 using AArch32.

8. Exceptions taken to EL1, or taken to EL2 because the value of [HCR\\_EL2.TGE](#) is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 1-7.

———— **Note** ————

When EL2 is using AArch32, the equivalent control for routing exceptions to EL2 is [HCR.TGE](#).

9. Exceptions taken from EL0 to EL2 because of one of the following configuration settings:

- [HSTR\\_EL2.Tn](#).
- [HCR\\_EL2.TIDCP](#).

———— **Note** ————

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are [HSTR.Tn](#) and [HCR.TIDCP](#).

10. Exceptions taken to EL2 because of configuration settings in the [CPTR\\_EL2](#).

———— **Note** ————

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, the equivalent controls are in the [HCPTR](#).

11. Exceptions taken to EL2 because of one of the following configuration settings:

- Any setting in [HCR\\_EL2](#), other than the TIDCP bit.
- Any setting in [CNTHCTL\\_EL2](#).
- Any setting in [MDCR\\_EL2](#).

———— **Note** ————

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, the equivalent controls are:

- Any setting in [HCR](#), other than the TIDCP bit.
- Any setting in [CNTHCTL](#) or [HDCR](#).

12. Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 1-11.

13. Exceptions caused by the SMC instruction being UNDEFINED because the value of [SCR\\_EL3.SMD](#) is 1.

14. Exceptions caused by the execution of an Exception generating instruction:

- For exceptions taken from AArch64 state, [Branches, Exception generating, and System instructions on page C3-156](#) defines these instructions.
- When executing in AArch32 state, the exception-generating instructions are SVC, HVC, SMC, and BKPT.

15. Exceptions taken to EL3 because of configuration settings in the [CPTR\\_EL3](#).

16. Exceptions taken to EL3 from Secure EL1 using AArch32, because of execution of the instructions listed in [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1870](#).

17. Exceptions taken to EL3 from EL0, EL1, or EL2 because of configuration settings in the [MDCR\\_EL3](#).

18. Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities 1-17.

19. Trapped floating-point exceptions, if supported. See [Floating-point exceptions and exception traps on page D1-1831](#).

20. SP alignment faults. See [SP alignment checking on page D1-1793](#).

21. Data Abort exceptions other than a Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk. That is, any Data Abort exception that is not covered by item 23. See [Exception from a Data abort on page D1-1811](#) and [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-2110](#). It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item 23.
22. Watchpoint exceptions. See [Watchpoint exceptions on page D2-1940](#).
23. Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk, see [External aborts on page D3-1997](#). It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item 21.

For items 21-23, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

———— **Note** —————

Exceptions generated by a translation table walk are reported and prioritized as either an Instruction Abort exception, priority 3 in this list, or a Data Abort exception, priority 21 in this list. See also [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-2110](#).

#### D1.13.4 Effect of Data Aborts

If an instruction that stores to memory generates a Data Abort, the value of each memory location that instruction stores to is either:

- Unchanged, if one of the following applies:
  - An MMU fault is generated.
  - A Watchpoint exception is generated.
  - An external abort is generated, if that external abort is taken synchronously.

———— **Note** —————

If an external abort is taken asynchronously, using the SError interrupt, it is outside the scope of the architecture to define the effect of the store on the memory location, because it depends on the system-specific nature of the external abort. However, in general, ARM recommends that such memory locations are not updated.

- UNKNOWN for any location for which no exception and no debug event is generated.

For external aborts and Watchpoint exceptions, the size of a memory location is defined as being the size for which a memory access is single-copy atomic.

———— **Note** —————

For the definition of a single-copy atomic access, see [Properties of single-copy atomic accesses on page B2-83](#).

For Data Aborts from load or store instructions executed in AArch64 state, if the:

**Data Abort is taken synchronously**

- If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
- If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
- If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.

**Data Abort is taken asynchronously, using the SError interrupt**

If the instruction was a load, the destination registers of the load take an UNKNOWN value if the SError interrupt is taken at a point in the instruction stream after the load.

### D1.13.5 Floating-point exceptions and exception traps

Execution of a floating-point instruction, or an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a *floating-point exception*.

---

**Note**

In AArch64 state, a floating-point instruction performs only a single floating-point operation. However, an Advanced SIMD instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an *operation*, rather than on an *instruction*.

---

The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:

- For an implementation that does provide this capability, [FPCR](#).{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the different floating-point exceptions.
- For an implementation that does not provide this capability, the [FPCR](#).{IDE, IXE, UFE, OFE, DZE, IOE} bits are RAZ/WI.

---

**Note**

The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

---

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level. This means that trapped floating-point exceptions taken:

- From EL0 are taken to EL1, unless they are taken from Non-secure state when the value of [HCR\\_EL2.TGE](#) is 1, when they are taken to EL2 instead.
- From EL1 are taken to EL1.
- From EL2 are taken to EL2.
- From EL3 are taken to EL3.

The exception is reported in the [ESR\\_ELx](#) for the Exception level to which it is taken.

In an implementation that includes synchronous exception generation for floating-point exceptions in AArch64 state:

- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception bits in the event of such an exception. For more information see [Combinations of floating-point exceptions on page D1-1832](#).
- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the [ESR\\_ELx](#) reports one exception associated with one element that the instruction uses. The architecture does not specify which element is reported, however the element that is reported is identified in the [ESR\\_ELx](#).

The `AArch64.FPTrappedException()` and `FPProcessException()` pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch64 state.

## Combinations of floating-point exceptions

Many pseudocode functions perform *floating-point operations*, including `FixedToFP()`, `FPAdd()`, `FPCompare()`, `FPCompareEQ()`, `FPCompareGE()`, `FPCompareGT()`, `FPDiv()`, `FPMMax()`, `FPMMin()`, `FPMul()`, `FPMulAdd()`, `FPRecipEstimate()`, `FPRecipStepFused()`, `FPRSqrtEstimate()`, `FPRSqrtStepFused()`, `FPSqrt()`, `FPSub()`, and `FPToFixed()`. All of these operations can generate floating-point exceptions.

### ———— Note ————

`FPAbs()` and `FPNeg()` are not classified as *floating-point operations* because:

- They cannot generate floating-point exceptions.
- The floating-point operation behavior described in the following sections does not apply to them:
  - [Flush-to-zero on page A1-51](#).
  - [NaN handling and the Default NaN on page A1-52](#).

More than one floating-point exception can occur on the same operation. The only combinations of floating-point exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other floating-point exceptions.

The priority order of these floating-point exceptions is that the Inexact exception is treated as lowest priority, and the Input Denormal exception is treated as highest priority.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, a floating-point exception on one operation is treated as higher priority than a floating-point exception on another operation if the occurrence of the second floating-point exception depends on the result of the first operation. Otherwise, it is `CONSTRAINED UNPREDICTABLE` which floating-point exception is treated as higher priority, where the exception prioritized might differ between different instances of the same two floating-point exceptions being generated on the same operation during execution of the instruction.

When none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative bit in the `FPSR` to be set to 1.

When a floating-point exception is trapped:

- It is `IMPLEMENTATION DEFINED` whether the `FPSR` is restored when the trapped floating-point exception is taken. If the `FPSR` is not restored then, then it is `CONSTRAINED UNPREDICTABLE` which untrapped floating-point exception, if any, are indicated by the corresponding `FPSR` cumulative exception bits having the value 1.
- In the `ESR_ELx` for the Exception level to which the trapped exception is taken, the value of the floating-point exception trapped bit for the highest priority trapped floating-point exception must be 1.  
In this `ESR_ELx`:
  - The value of the floating-point exception trapped bit for any other untrapped floating-point exception generated by the same operation must be 0. This applies to both higher priority and lower priority untrapped floating point exceptions.
  - The value of the floating-point exception trapped bit for any lower priority trapped floating-point exception generated by the same operation might be 1, but the architecture does not require this.

For trapped floating-point exceptions from Advanced SIMD instructions, the architecture does not define the floating-point exception prioritization between different elements of the instruction. The architectural requirements for floating-point exception prioritization apply only to multiple floating-point exceptions generated on the same element of an Advanced SIMD operation.

---

**Note**

---

An implementation might provide information about a lower priority or untrapped floating-point exceptions in an IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.

---

## D1.14 Asynchronous exception types, routing, masking and priorities

In the ARMv8-A architecture, asynchronous exceptions that are taken to AArch64 state are also known as *interrupts*.

There are two types of interrupts:

- |                            |  |
|----------------------------|--|
| <b>Physical interrupts</b> | Are signals sent to the PE from outside the PE. They are: <ul style="list-style-type: none"><li>• SError. System Error.</li><li>• IRQ.</li><li>• FIQ.</li></ul>  |
| <b>Virtual interrupts</b>  | Are interrupts that software executing at EL2 can enable and make pending. A virtual interrupt is taken from Non-secure EL0 or Non-secure EL1 to Non-secure EL1.<br>Virtual interrupts have names that correspond to the physical interrupts: <ul style="list-style-type: none"><li>• vSError.</li><li>• vIRQ.</li><li>• vFIQ.</li></ul> |

---

### Note

- For information about how virtual interrupts might be used see [Virtual interrupt usage model on page D1-1783](#).
  - The SError interrupt replaces the ARMv7 asynchronous abort. The new name better describes the nature of the exception, and means that, in AArch64 state, it is categorized as a unique exception class, with EC encoding 0x2F.
- 

An external abort generated by the memory system might be taken asynchronously using the SError interrupt. The effect of a failed memory access is described in [Effect of Data Aborts on page D1-1830](#).

Each physical interrupt type can be assigned a target Exception level of EL1, EL2 or EL3, as shown in [Asynchronous exception routing](#).

When an interrupt occurs:

- On taking an SError or a vSError interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is updated with the encoding for an SError interrupt. See [Exception classes and the ESR\\_ELx syndrome registers on page D1-1801](#).
- On taking an IRQ, vIRQ, FIQ or vFIQ interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is not updated.

The remainder of this section contains the following:

- [Asynchronous exception routing](#).
- [Asynchronous exception masking on page D1-1836](#).
- [Virtual interrupts on page D1-1839](#).
- [Prioritization and recognition of interrupts on page D1-1841](#).
- [Taking an interrupt or other exception during a multiple-register load or store on page D1-1841](#).

### D1.14.1 Asynchronous exception routing

The following tables show the routing of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see [Table D1-12 on page D1-1835](#).
- For implementations that include EL3 but not EL2, see [Table D1-13 on page D1-1836](#).
- For implementations that include EL2 but not EL3, see [Table D1-14 on page D1-1836](#).

In the tables:

**C** Indicates that the interrupt is not taken, regardless of the Process state interrupt mask.

**n/a** Not applicable:

- In an implementation that includes EL3:
  - The PE cannot be executing at EL2 when the value of [SCR\\_EL3.NS](#) is 0.
  - The PE cannot be executing at EL3 when the value of [SCR\\_EL3.NS](#) is 1.
- In an implementation that includes EL2, the PE cannot be executing at Non-secure EL1 when the value of [HCR.TGE](#) is 1.

**HCR** In [Table D1-12](#), including in the table footnote:

- When EL2 is using AArch64 [HCR](#) refers to the AArch64 register [HCR\\_EL2](#).
- When EL2 is using AArch32 [HCR](#) refers to the AArch32 register [HCR](#).

When the *Effective value* of [HCR](#).{E2H, TGE} is:

**{0, 1}** The *Effective value* of each of the [HCR](#).{AMO, IMO, FMO} fields is 1. The virtual exceptions are disabled.

**{1, 1}** The *Effective value* of each of the [HCR](#).{AMO, IMO, FMO} fields is 0.

**Table D1-12 Routing when both EL3 and EL2 are implemented**

<a href="#">SCR_EL3</a>			<a href="#">HCR</a>			Target Exception level when executing at:			
NS	EA IRQ FIQ	RW	E2H <sup>a</sup>	TGE	AMO IMO FMO	EL0	EL1	EL2	EL3
0	0	x	x	x	x	EL1	EL1	n/a	C
	1	x	x	x	x	EL3	EL3	n/a	EL3
1	0	x	x	0	1	EL2	EL2	EL2	n/a
			0	1	1	EL2	n/a	EL2	n/a
	0		x	0	0	EL1	EL1	EL2	n/a
			1	1	0	EL1	n/a	EL2	n/a
	1		x	0	0	EL1	EL1	C	n/a
			1	1	0	EL1	n/a	C	n/a
	1	x	x	x	x	EL3	EL3	EL3	n/a

- a. When the implementation does not include [ARMv8.1-VHE](#), the [HCR\\_EL2.E2H](#) field is not implemented and behavior is as if the value of E2H is 0.

**Table D1-13 Routing when EL3 is implemented and EL2 is not implemented**

<b>SCR_EL3</b>		<b>Target Exception level when executing at</b>		
<b>NS</b>	<b>EA IRQ FIQ</b>	<b>EL0</b>	<b>EL1</b>	<b>EL3</b>
0	0	EL1	EL1	C
	1	EL3	EL3	EL3
1	0	EL1	EL1	n/a
	1	EL3	EL3	n/a

**Table D1-14 Routing when EL3 is not implemented and EL2 is implemented**

<b>HCR_EL2</b>			<b>Target Exception level when executing at</b>		
<b>E2H<sup>a</sup></b>	<b>TGE</b>	<b>AMO IMO FMO</b>	<b>EL0</b>	<b>EL1</b>	<b>EL2</b>
0	1	1	EL2	n/a	EL2
x	0	0	EL1	EL1	C
		1	EL2	EL2	EL2
1	1	0	EL1	n/a	C

a. When the implementation does not include [ARMv8.1-VHE](#), the [HCR\\_EL2.E2H](#) field is not implemented and behavior is as if the value of E2H is 0.

## D1.14.2 Asynchronous exception masking

When an interrupt is masked, it means that it cannot be taken. Instead, it remains pending.

When executing in AArch64 state, interrupts are masked implicitly when the target Exception level of the interrupt is lower than the current Exception level.

In addition, interrupts can be masked when the target Exception level is the current Exception level. The controls for this are:

**SError**     [PSTATE.A](#)  
**IRQ**        [PSTATE.I](#)  
**FIQ**        [PSTATE.F](#)

When the target Exception level is higher than the current Exception level:

- If the target Exception level is EL2 or EL3, the interrupt cannot be masked by the [PSTATE](#).{A, I, F} bits.
- If the target Exception level is EL1, the interrupt can be masked by the [PSTATE](#).{A, I, F} bits.

### ————— **Note** —————

- The ability to execute in EL0 with interrupts to EL1 masked is required by some user level driver code.
- The [PSTATE](#).{A, I, F} bits can mask both physical interrupts and virtual interrupts.

- The ARMv8-A architecture does not support *Non-maskable FIQ* (NMF1) operations. This means that it does not provide a configuration option to override the masking of FIQs by `PSTATE.F`.

On taking any exception to an Exception level using AArch64, all of `PSTATE.{A, I, F}` are set to 1, masking all interrupts that target that Exception level.

The following tables show the masking of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see [Table D1-15](#).
- For implementations that include EL3 but not EL2, see [Table D1-16 on page D1-1838](#).
- For implementations that include EL2 but not EL3, see [Table D1-17 on page D1-1839](#).

For the masking of virtual interrupts, see [Virtual interrupts on page D1-1839](#).

In the tables:

- A** When the interrupt is asserted it is taken regardless of the value of the Process state interrupt mask.
- B** When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is not taken. If the value of the mask is 0 the interrupt is taken.
- C** When the interrupt is asserted it is not taken, regardless of the value of the Process state interrupt mask.
- When the value of `SCR_EL3.RW` is 0, EL2 is using AArch32, and there is no `HCR.E2H` bit.
- n/a** Not applicable:
- In an implementation that includes EL3, the PE cannot be executing at EL2 when the value of `SCR_EL3.NS` is 0.
- The PE cannot be executing at Non-secure EL1 when the value of `HCR.TGE` is 1.
- HCR** In [Table D1-15](#), including in the table footnote:
- When EL2 is using AArch64 `HCR` refers to the AArch64 register `HCR_EL2`.
  - When EL2 is using AArch32 `HCR` refers to the AArch32 register `HCR`.
- When the *Effective value* of `HCR.{E2H, TGE}` is:
- {0, 1}** The *Effective value* of each of the `HCR.{AMO, IMO, FMO}` fields is 1. The virtual exceptions are disabled.
- {1, 1}** The *Effective value* of each of the `HCR.{AMO, IMO, FMO}` fields is 0.

**Table D1-15 Physical interrupt target and masking when both EL3 and EL2 are implemented**

<b>SCR_EL3</b>			<b>HCR</b>			<b>Target Exception level</b>	<b>Effect of the interrupt mask when executing at:</b>			
<b>NS</b>	<b>EA IRQ FIQ</b>	<b>RW</b>	<b>E2H<sup>a</sup></b>	<b>TGE</b>	<b>AMO IMO FMO</b>		<b>EL0</b>	<b>EL1</b>	<b>EL2</b>	<b>EL3</b>
0	0	x	x	x	x	EL1	B	B	n/a	C
	1	x	x	x	x	EL3	A	A	n/a	B

**Table D1-15 Physical interrupt target and masking when both EL3 and EL2 are implemented (continued)**

SCR_EL3			HCR			Target Exception level	Effect of the interrupt mask when executing at:			
NS	EA IRQ FIQ	RW	E2H <sup>a</sup>	TGE	AMO IMO FMO		EL0	EL1	EL2	EL3
1	0	0	-	0	0	EL1	B <sup>b</sup>	B <sup>b</sup>	B <sup>b</sup>	C
					1	EL2	A <sup>b</sup>	A <sup>b</sup>	B <sup>b</sup>	C
					1	EL2	A <sup>b</sup>	n/a	B <sup>b</sup>	C
		1	x	0	0	EL1	B	B	C	C
					1	EL2	A	A	B	C
					0	EL2	A	n/a	B	C
					1	EL2	B	n/a	B	C
	1	x	x	x	x	EL3	A	A	A	B

- a. When the implementation does not include [ARMv8.1-VHE](#), the [HCR\\_EL2.E2H](#) field is not implemented and behavior is as if the value of E2H is 0.
- b. In these cases, the exception is taken from an Exception level using AArch32 to an Exception level using AArch32, and therefore the masking rules defined in [Asynchronous exception masking controls on page G1-4368](#) apply.

**Table D1-16 Physical interrupt target and masking when EL3 is implemented and EL2 is not implemented**

SCR_EL3		Target Exception level	Effect of the interrupt mask when executing at:		
NS	EA IRQ FIQ		EL0	EL1	EL3
x	0	EL1	B	B	C
	1	EL3	A	A	B

**Table D1-17 Physical interrupt target and masking when EL3 is not implemented and EL2 is implemented**

<b>HCR_EL2</b>			<b>Target Exception level</b>	<b>Effect of the interrupt mask when executing at:</b>		
<b>E2H<sup>a</sup></b>	<b>TGE</b>	<b>AMO IMO FMO</b>		<b>EL0</b>	<b>EL1</b>	<b>EL2</b>
x	0	0	EL1	B	B	C
		1	EL2	A	A	B
0	1	x	EL2	A	n/a	B
1	1	x	EL2	B	n/a	B

a. If the implementation does not include [ARMv8.1-VHE](#), the [HCR.E2H](#) field is not implemented and behavior is as if the value of E2H is 0.

### D1.14.3 Virtual interrupts

When the value of [HCR\\_EL2.TGE](#) is 0, setting an [HCR\\_EL2.{FMO, IMO, AMO}](#) routing control bit to 1 enables the corresponding virtual interrupt. When the value of [HCR\\_EL2.TGE](#) is 1 all virtual interrupts are disabled.

Virtual interrupts can only be taken from Non-secure EL0 or Non-secure EL1 to Non-secure EL1. When a virtual interrupt type is enabled, that type of interrupt can be generated by:

- Software setting the corresponding virtual interrupt pending bit, [HCR\\_EL2.{VSE, VI, VF}](#), to 1.
- For a vIRQ or a vFIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the *ARM Generic Interrupt Controller Architecture Specification*.

#### ———— **Note** ————

For a usage model for virtual interrupts, see *Virtual interrupt usage model* on page D1-1783.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the [ISR\\_EL1](#).

Each virtual interrupt type can be masked when execution is in Non-secure EL1 or EL0, by using the same Process State mask bits that mask the physical interrupts, [PSTATE.{A, I, F}](#).

When execution is in Secure state, or at EL2, all types of virtual interrupt are always masked.

[Table D1-18](#) summarizes the bits that enable virtual interrupts and the bits that cause virtual interrupts to be pending.

**Table D1-18 HCR\_EL2 interrupt control bits**

<b>Virtual interrupt type</b>	<b>Enable control<sup>a</sup></b>	<b>Cause a virtual interrupt to be pending</b>
vSError	<a href="#">HCR_EL2.AMO</a>	<a href="#">HCR_EL2.VSE</a>
vIRQ	<a href="#">HCR_EL2.IMO</a>	<a href="#">HCR_EL2.VI</a>
vFIQ	<a href="#">HCR_EL2.FMO</a>	<a href="#">HCR_EL2.VF</a>

a. Applies only when the value of [HCR\\_EL2.TGE](#) is 0, otherwise the virtual interrupts are disabled.

On taking a vIRQ or a vFIQ interrupt, the corresponding virtual interrupt pending bit in the [HCR\\_EL2](#) retains its state.

On taking a vSError interrupt, [HCR\\_EL2.VSE](#) is cleared to 0.

———— **Note** ————

This means that if the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing at EL2 or EL3 to set their corresponding virtual interrupt pending bits to 0.

As with physical interrupts:

- Taking a vSError interrupt to an Exception level using AArch64 updates [ESR\\_EL1](#) with the dedicated encoding for an SError interrupt. For the encoding, see [Exception classes and the ESR\\_ELx syndrome registers on page D1-1801](#).
- Taking a vIRQ or a vFIQ interrupt to an Exception level using AArch64 does not update the [ESR\\_EL1](#).

The following table shows the masking of virtual interrupts when the highest implemented Exception level is using AArch64. In the table:

<b>B</b>	When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is not taken. If the value of the mask is 0 the interrupt is taken.
<b>C</b>	When the interrupt is asserted it is not taken, regardless of the value of the Process state mask.
<b>n/a</b>	Not applicable: <ul style="list-style-type: none"> <li>• In an implementation that includes EL3, the PE cannot be executing at EL2 when the value of <a href="#">SCR_EL3.NS</a> is 0.</li> <li>• The PE cannot be executing at Non-secure EL1 when the value of <a href="#">HCR.TGE</a> is 1.</li> </ul>
<b>HCR</b>	In <a href="#">Table D1-19</a> , including in the table footnote: <ul style="list-style-type: none"> <li>• When EL2 is using AArch64 <a href="#">HCR</a> refers to the AArch64 register <a href="#">HCR_EL2</a>.</li> <li>• When EL2 is using AArch32 <a href="#">HCR</a> refers to the AArch32 register <a href="#">HCR</a>.</li> </ul> When the <i>Effective value</i> of <a href="#">HCR</a> .{E2H, TGE} is: <ul style="list-style-type: none"> <li><b>{0, 1}</b> The <i>Effective value</i> of each of the <a href="#">HCR</a>.{AMO, IMO, FMO} fields is 1. The virtual exceptions are disabled.</li> <li><b>{1, 1}</b> The <i>Effective value</i> of each of the <a href="#">HCR</a>.{AMO, IMO, FMO} fields is 0.</li> </ul>

**Table D1-19 Virtual interrupt masking**

<a href="#">SCR_EL3</a>		<a href="#">HCR</a>			Effect of the interrupt mask when executing at:			
<b>NS</b>	<b>EA IRQ FIQ</b>	<b>E2H<sup>a</sup></b>	<b>TGE</b>	<b>AMO IMO FMO</b>	<b>EL0</b>	<b>EL1</b>	<b>EL2</b>	<b>EL3</b>
0	x	x	x	x	C	C	n/a	C
1	x	x	0	0	C	C	C	C
				1	B	B	C	C
			1	x	C	n/a	C	C

a. If EL2 is using AArch32 or the implementation does not include [ARMv8.1-VHE](#), the [HCR.E2H](#) field is not implemented and behavior is as if the value of E2H is 0.

#### D1.14.4 Prioritization and recognition of interrupts

The ARMv8-A architecture does not define when interrupts are taken. The prioritization of interrupts, including virtual interrupts, is IMPLEMENTATION DEFINED.

---

**Note**

As indicated at the start of *Asynchronous exception types, routing, masking and priorities* on page D1-1834, in AArch64 state all possible asynchronous exceptions are defined as *interrupts*.

---

Any interrupt that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event, provided that the pending interrupt is not masked:

- Execution of an ISB instruction.
- Exception entry.
- Exception return.
- Exit from Debug state.

---

**Note**

- If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define whether the PE takes the interrupt or the synchronous exception first.
  - The *ISR\_EL1* identifies any pending interrupts.
  - Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.
- 

In the absence of a specific requirement to take an interrupt, the architecture only requires that unmasked pending interrupts are taken in finite time.

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken then it must be taken before the first *Context synchronization event* after the interrupt was changed to not pending.

#### D1.14.5 Taking an interrupt or other exception during a multiple-register load or store

In AArch64 state, interrupts can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.

If an interrupt, or another exception, is taken from AArch64 during the execution of an instruction that performs a sequence of memory accesses, rather than a single single-copy atomic access, then:

- For a load, any register being loaded by the instruction other than ones used in the generation of the address by the instruction, can contain an UNKNOWN value. Registers used in the generation of the address are restored to their initial value.
- For a store, any data location being stored to by the instruction can contain an UNKNOWN value.
- For either a load or a store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.

---

**Note**

- This interrupt behavior is in contrast to behavior in AArch32 state, when interrupts cannot be taken during a sequence of memory accesses caused by a single load or store instruction.
  - In both Execution states, synchronous data abort exceptions can be taken during the execution of an instruction that performs a sequence of memory accesses.
  - Software must avoid using multiple-register load and store instructions for accesses to Device memory, particularly to Device memory with the non-Gathering attribute, because an exception taken during the load or store can result in repeated accesses.
-

## D1.15 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch64 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an *instruction enable*, an *instruction disable*, or a *trap control*:

### Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Exception level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

**Trap controls** A trap control determines whether one or more particular instructions, whenever executed at a particular Exception level, are *trapped*.

A trapped instruction generates a *Trap exception*.

For trap controls provided by:

- EL1** Trap exceptions are taken to EL1, unless routed from Non-secure EL0 to EL2 because [HCR\\_EL2.TGE](#) is 1 as described in [Routing exceptions from Non-secure EL0 to EL2 on page D1-1827](#).  
For descriptions of these controls see [EL1 configurable controls on page D1-1843](#).
- EL2** Trap exceptions are taken to EL2.  
For descriptions of these controls see [EL2 configurable controls on page D1-1851](#).
- EL3** Trap exceptions are taken to EL3.  
For descriptions of these controls see [EL3 configurable controls on page D1-1869](#).

### ———— Note ————

The definitions of *traps* and *enables and disables* overlap, and the classification of some controls is historical. In AArch64 state, the most significant characteristic of an exception report is the [ESR\\_ELx.EC](#) value with which it is reported. Describing a register control field as an instruction enable, an instruction disable, or a trap control, gives no indication of how an exception that is generated as a consequence of the value of that field is handled or reported.

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if both of the following apply:

- The instruction generating the exception does not also generate a higher priority exception. [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) defines the prioritization of different exceptions on the same instruction.
- The instruction is not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state it is executed in. UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions can generate exceptions as a result of these controls, but the architecture does not require them to do so.

Exceptions generated as a result of these controls are synchronous exceptions.

Exceptions are reported in the [ESR\\_ELx](#), with an EC value that indicates the Exception class, and:

- Many cases, including all traps, are reported with a non-zero EC value and an associated syndrome.
- Some cases where an instruction is UNDEFINED are reported with an EC value 0x00, the value for an exception for an unknown or uncategorized reason, and in these cases no syndrome is provided. [ISS encoding for exceptions with an unknown reason on page D7-2259](#) identifies the cases that are reported with EC value 0x00.

Table D1-8 on page D1-1802 lists the EC values that are used for exceptions that result from traps, enables, and disables.

#### Note

- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, `SCTLR_EL1.DZE` is a trap control even though DZE means DC ZVA Enable.
- In addition to the controls described in this section, a *routing control*, `HCR_EL2.TGE`, can be used to route exceptions from EL0 to EL2. See *Routing exceptions from Non-secure EL0 to EL2 on page D1-1827*.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

This section is organized as follows:

- *Register access instructions.*
- *EL1 configurable controls.*
- *EL2 configurable controls on page D1-1851.*
- *EL3 configurable controls on page D1-1869.*

### D1.15.1 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:

- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

### D1.15.2 EL1 configurable controls

These controls are in `_EL1` System registers. The resulting exceptions might be taken from either Execution state. `SPSR_EL1.M[4]` indicates which Execution state the exception was taken from.

Table D1-20 shows the `_EL1` System registers that contain these controls.

Table D1-20 `_EL1` registers that contain instruction enables and disables, and trap controls

Register name	Register description
<code>SCTLR_EL1</code>	System Control Register, EL1
<code>CPACR_EL1</code>	Architectural Feature Access Control Register
<code>MDSCR_EL1</code>	Monitor System Debug Control Register
<code>PMUSERENR_EL0</code>	Performance Monitors User Enable Register

Table D1-21 summarizes the controls.

Table D1-21 Instruction enables and disables, and trap controls, provided by EL1

Control	Control type <sup>a</sup>	Description
<code>SCTLR_EL1.UCI</code>	T	<i>Traps to EL1 of EL0 execution of cache maintenance instructions on page D1-1844</i>
<code>SCTLR_EL1.UCT</code>	T	<i>Traps to EL1 of EL0 accesses to the <code>CTR_EL0</code> on page D1-1845</i>
<code>SCTLR_EL1.{nTWE, nTWI}</code>	T	<i>Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1845</i>

**Table D1-21 Instruction enables and disables, and trap controls, provided by EL1 (continued)**

Control	Control type <sup>a</sup>	Description
SCTLR_EL1.DZE	T	Traps to EL1 of EL0 execution of DC ZVA instructions on page D1-1846
SCTLR_EL1.UMA	T	Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-1846
SCTLR_EL1.{SED, ITD}	D	Disabling or enabling EL0 use of AArch32 deprecated functionality on page D1-1847
SCTLR_EL1.CP15BEN	E	
CPACR_EL1.TTA	T	Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1847
CPACR_EL1.FPEN	T	Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality on page D1-1848
MDSCR_EL1.TDCC	T	Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers on page D1-1848
CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}	T	Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1849
PMUSERENR_EL0.{ER, CR, SW, EN}	T	Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1850

a. See Table D1-22.

**Table D1-22 Control types, for exceptions taken to EL1**

Abbreviation	Type	See
D	Disable	Instruction enables and instruction disables on page D1-1842
E	Enable	Instruction enables and instruction disables on page D1-1842
T	Trap	Trap controls on page D1-1842

### Traps to EL1 of EL0 execution of cache maintenance instructions

SCTLR\_EL1.UCI traps EL0 execution of cache maintenance instructions to EL1:

- 1** EL0 execution of cache maintenance instructions is not trapped to EL1.
- 0** Any attempt to execute a cache maintenance instruction at EL0 is trapped to EL1.

Table D1-23 shows the instructions that are trapped to EL1, and how the exceptions are reported in ESR\_EL1:

**Table D1-23 Instructions trapped to EL1 when SCTLR\_EL1.UCI is 0**

Traps from	Trapped instructions	Syndrome reporting in ESR_EL1
AArch64 state	DC CVAU, DC CIVAC, DC CVAC, DC CVAP, IC IVAU	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 <sup>a</sup>
AArch32 state	n/a	n/a

- a. If HCR\_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR\_EL2 using the same EC values as shown in the table.

## Traps to EL1 of EL0 accesses to the CTR\_EL0

[SCTLR\\_EL1](#).UCT traps EL0 accesses to the [CTR\\_EL0](#) to EL1:

- 1** EL0 accesses to the [CTR\\_EL0](#) are not trapped to EL1.
- 0** EL0 accesses to the [CTR\\_EL0](#) are trapped to EL1.

Table D1-24 shows how the exceptions are reported in [ESR\\_EL1](#):

**Table D1-24 Register accesses trapped to EL1 when [SCTLR\\_EL1](#).UCT is 0**

Traps from	Register	Syndrome reporting in <a href="#">ESR_EL1</a>
AArch64	<a href="#">CTR_EL0</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 <sup>a</sup>
AArch32	n/a	n/a

- a. If [HCR\\_EL2](#).TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR\\_EL2](#) using the same EC values as shown in the table.

## Traps to EL1 of EL0 execution of WFE and WFI instructions

[SCTLR\\_EL1](#).{nTWE, nTWI} trap EL0 execution of WFE and WFI instructions to EL1:

### [SCTLR\\_EL1](#).nTWE

- 1** EL0 execution of WFE instructions is not trapped to EL1.
- 0** Any attempt to execute a WFE instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

### [SCTLR\\_EL1](#).nTWI

- 1** EL0 execution of WFI instructions is not trapped to EL1.
- 0** Any attempt to execute a WFI instruction at EL0 is trapped EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

Table D1-25 shows how the exceptions are reported in [ESR\\_EL1](#):

**Table D1-25 Instructions trapped to EL1 when [SCTLR\\_EL1](#).{nTWE, nTWI} are 0**

Trap control	Traps from	Trapped instructions	Syndrome reporting in <a href="#">ESR_EL1</a>
<a href="#">SCTLR_EL1</a> .nTWE	Both Execution states	WFE	Trapped WFI or WFE instruction, using EC value 0x01 <sup>a</sup>
<a href="#">SCTLR_EL1</a> .nTWI		WFI	

- a. If [HCR\\_EL2](#).TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR\\_EL2](#) using the same EC values as shown in the table.

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

### ————— **Note** —————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait for Event mechanism and Send event on page D1-1879.](#)
- [Wait For Interrupt on page D1-1882.](#)

## Traps to EL1 of EL0 execution of DC ZVA instructions

[SCTLR\\_EL1.DZE](#) traps EL0 execution of DC ZVA instructions to EL1:

- 1** EL0 execution of DC ZVA instructions is not trapped to EL1.
- 0** Any attempt to execute a DC ZVA instruction at EL0 is trapped to EL1. Reading the [DCZID\\_EL0](#) returns a value that indicates that DC ZVA instructions are not implemented.

Table D1-26 shows how the exceptions are reported in [ESR\\_EL1](#):

**Table D1-26 Instruction trapped to EL1 when [SCTLR\\_EL1.DZE](#) is 0**

Traps from	Trapped instruction	Syndrome reporting in <a href="#">ESR_EL1</a>
AArch64 state	<a href="#">DC ZVA</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 <sup>a</sup>
AArch32 state	n/a	n/a

- a. If [HCR\\_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR\\_EL2](#) using the same EC values as shown in the table.

## Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks

[SCTLR\\_EL1.UMA](#) traps EL0 execution of MSR and MRS instructions that access the [PSTATE](#).{D, A, I, F} masks to EL1:

- 1** EL0 execution of MSR or MRS instructions that access the [DAIF](#) is not trapped to EL1.
- 0** Any attempt at EL0 to execute an MSR or an MRS instruction that accesses the [DAIF](#) is trapped to EL1.

Table D1-27 shows how the exceptions are reported in [ESR\\_EL1](#):

**Table D1-27 Instructions trapped to EL1 when [SCTLR\\_EL1.UMA](#) is 0**

Taken from	Disabled instructions	Syndrome reporting in <a href="#">ESR_EL1</a>
AArch64 state	<a href="#">MRS</a> , <a href="#">MSR (register)</a> , <a href="#">MSR (immediate)</a> , that access the <a href="#">DAIF</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 <sup>a</sup>
AArch32 state	n/a	n/a

- a. If [HCR\\_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR\\_EL2](#) using the same EC values as shown in the table.

## Disabling or enabling EL0 use of AArch32 deprecated functionality

Table D1-28 shows the deprecated AArch32 functionality that might have disable controls in the [SCTLR\\_EL1](#):

- The SED control is always implemented.
- Whether each of the ITD, CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

These [SCTLR\\_EL1](#) controls apply only to execution at EL0 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL0 using AArch32. Table D1-28 shows how the exceptions are reported in [ESR\\_EL1](#):

**Table D1-28 EL1 controls for disabling and enabling EL0 use of AArch32 deprecated functionality**

Deprecated AArch32 functionality	Instruction enable or disable in the <a href="#">SCTLR_EL1</a>	Disabled instructions	Syndrome reporting in <a href="#">ESR_EL1</a> <sup>a</sup>
SETEND instructions	SED <sup>b</sup>	<a href="#">SETEND</a> instructions	Exception for an unknown reason, using EC value 0x00
Some uses of IT instructions	ITD <sup>c</sup>	See the <a href="#">SCTLR_EL1.IT</a> description	
Accesses to the <a href="#">CP15DMB</a> , <a href="#">CP15DSB</a> , and <a href="#">CP15ISB</a> barrier instructions	CP15BEN <sup>d</sup>	MCR accesses to the <a href="#">CP15DMB</a> , <a href="#">CP15DSB</a> , and <a href="#">CP15ISB</a> instructions	

- If [HCR\\_EL2.TGE](#) is 1 and the PE is in Non-secure state, the exception is routed to EL2 and reported in [ESR\\_EL2](#) using the EC value shown in the table.
- SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
- IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
- System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

### Note

- The uses of the IT instruction, and use of the [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) barrier instructions, are deprecated for performance reasons.
- The [SCTLR](#) provides similar controls that apply when EL1 is using AArch32, and the [HSCTLR](#) provides similar controls that apply when EL2 is using AArch32.

## Traps to EL1 of EL0 and EL1 System register accesses to the trace registers

[CPACR\\_EL1.TTA](#) traps EL0 and EL1 System register accesses to the trace registers to EL1.

- |          |   |
|----------|---|
| <b>1</b> | EL0 and EL1 System register accesses to the trace registers are trapped to EL1.     |
| <b>0</b> | EL0 and EL1 System register accesses to the trace registers are not trapped to EL1. |

### Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and the resulting exception is higher priority than a [CPACR\\_EL1.TTA](#) Trap exception.
- The ARMv8-A architecture does not provide traps on trace register accesses through the optional Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see [Register access instructions on page D1-1843](#).

Table D1-29 shows the registers for which accesses are trapped to EL1 when [CPACR\\_EL1.TTA](#) is 1, and how the exceptions are reported in [ESR\\_EL1](#):

**Table D1-29 Register accesses trapped to EL1 when [CPACR\\_EL1.TTA](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL1</a>
AArch64 state	All implemented trace registers	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18. <sup>a</sup>
AArch32 state	All implemented trace registers	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.<sup>a</sup></li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.<sup>a</sup></li> </ul>

- a. If [HCR\\_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR\\_EL2](#) using the same EC values as shown in the table.

### Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality

When EL1 is using AArch64, [CPACR\\_EL1.FPEN](#) traps EL0 and EL1 accesses to the SIMD and floating-point registers to EL1:

<b>00</b>	Causes any instructions in EL0 or EL1 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped.
<b>01</b>	Causes any instructions in EL0 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped, but does not cause any instruction in EL1 to be trapped.
<b>10</b>	Causes any instructions in EL0 or EL1 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped.
<b>11</b>	Does not cause any instruction to be trapped.

Table D1-30 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL1](#):

**Table D1-30 Register accesses trapped to EL1 by [CPACR\\_EL1.FPEN](#)**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL1</a>
EL0 and EL1 using AArch64, or EL0 using AArch64 only <sup>a</sup> .	<a href="#">FPCR</a> , <a href="#">FPSR</a> , and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See <i>The SIMD and floating-point registers, V0-V31</i> on page D1-1786.	Trapped access to a SIMD or floating-point register, resulting from <a href="#">CPACR_EL1.FPEN</a> or <a href="#">CPTR_ELx.TFP</a> , using EC value 0x07 <sup>b</sup>
EL0 using AArch32	<a href="#">FPSCR</a> , and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See <i>Advanced SIMD and floating-point System registers</i> on page G1-4415.	Trapped access to a SIMD or floating-point register, resulting from <a href="#">CPACR_EL1.FPEN</a> or <a href="#">CPTR_ELx.TFP</a> , using EC value 0x07 <sup>b</sup>

- a. As described at the start of this subsection, the value of [CPACR\\_EL1.FPEN](#) determines whether the trap applies only to accesses from EL0, or applies to both accesses from EL1 and accesses from EL0.
- b. If [HCR\\_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR\\_EL2](#) using EC value 0x00.

### Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers

[MDSCR\\_EL1.TDCC](#) traps EL0 accesses to the DCC registers to EL1:

<b>1</b>	EL0 accesses to the DCC registers are trapped to EL1.
<b>0</b>	EL0 accesses to the DCC registers are not trapped to EL1.

Traps of AArch32 accesses to [DBGDTRRXint](#) and [DBGDTRTXint](#) are ignored in Debug state.

Traps of AArch64 accesses to [DBGDTR\\_EL0](#), [DBGDTRRX\\_EL0](#), and [DBGDTRTX\\_EL0](#) are ignored in Debug state.

[Table D1-31](#) shows the accesses that are trapped, and how the exceptions are reported in [ESR\\_EL1](#):

**Table D1-31 Accesses trapped to EL1 when [MDSCR\\_EL1.TDCC](#) is 1**

Traps from	Trapped accesses	Syndrome reporting in <a href="#">ESR_EL1</a>
AArch64 state	Accesses to the <a href="#">MDCCSR_EL0</a> , <a href="#">DBGDTR_EL0</a> , <a href="#">DBGDTRTX_EL0</a> and <a href="#">DBGDTRRX_EL0</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 <sup>a</sup>
AArch32 state	<ul style="list-style-type: none"> <li>MCR of <a href="#">DBGDSCRint</a>, <a href="#">DBGDTRRXint</a>, and, if implemented, <a href="#">DBGDIDR</a>, <a href="#">DBGDSAR</a> and <a href="#">DBGDRAR</a>.</li> <li>MCR to <a href="#">DBGDTRTXint</a>.</li> </ul>	Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05 <sup>a</sup>
	<ul style="list-style-type: none"> <li>LDC access to <a href="#">DBGDTRTXint</a>.</li> <li>STC access to <a href="#">DBGDTRRXint</a>.</li> </ul>	Trapped LDC or STC access, using EC value 0x06 <sup>a</sup>
	If implemented, MRRC of <a href="#">DBGDSAR</a> and <a href="#">DBGDRAR</a> .	Trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C <sup>a</sup>

- a. If [HCR\\_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR\\_EL2](#) using the same EC values as shown in the table.

### Traps to EL1 of EL0 accesses to the Generic Timer registers

[CNTKCTL\\_EL1](#).{[ELOPTEN](#), [ELOVTEN](#), [EL0PCTEN](#), [EL0VCTEN](#)} trap EL0 accesses to the Generic Timer registers to EL1, as follows:

- [CNTKCTL\\_EL1.ELOPTEN](#) traps EL0 accesses to the physical timer registers.
- [CNTKCTL\\_EL1.ELOVTEN](#) traps EL0 accesses to the virtual timer registers.
- [CNTKCTL\\_EL1.EL0PCTEN](#) traps EL0 accesses to the frequency register and physical counter register.
- [CNTKCTL\\_EL1.EL0VCTEN](#) traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:

- 1 EL0 accesses are not trapped to EL1.  
0 EL0 accesses are trapped to EL1.

Accesses to the frequency register, [CNTFRQ\\_EL0](#) or [CNTFRQ](#), are only trapped if [CNTKCTL\\_EL1.EL0PCTEN](#) and [CNTKCTL\\_EL1.EL0VCTEN](#) are both 0.

[Table D1-32](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL1](#):

**Table D1-32 Register accesses trapped from EL0 to EL1 by [CNTKCTL\\_EL1](#) trap controls**

Traps from	Trap control	Registers	Syndrome reporting in <a href="#">ESR_EL1</a>
AArch64 state	<a href="#">ELOPTEN</a>	<a href="#">CNTP_CTL_EL0</a> , <a href="#">CNTP_CVAL_EL0</a> , <a href="#">CNTP_TVAL_EL0</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 <sup>a</sup>
	<a href="#">ELOVTEN</a>	<a href="#">CNTV_CTL_EL0</a> , <a href="#">CNTV_CVAL_EL0</a> , <a href="#">CNTV_TVAL_EL0</a>	
	<a href="#">EL0PCTEN</a>	<a href="#">CNTFRQ_EL0</a> , <a href="#">CNTPCT_EL0</a>	
	<a href="#">EL0VCTEN</a>	<a href="#">CNTFRQ_EL0</a> , <a href="#">CNTVCT_EL0</a>	

**Table D1-32 Register accesses trapped from EL0 to EL1 by CNTKCTL\_EL1 trap controls (continued)**

Traps from	Trap control	Registers	Syndrome reporting in ESR_EL1
AArch32 state	EL0PTEN	CNTP_CTL, CNTP_CVAL, CNTP_TVAL	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03<sup>a</sup></li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04<sup>a</sup></li> </ul>
	EL0VTEN	CNTV_CTL, CNTV_CVAL, CNTV_TVAL	
	EL0PCTEN	CNTPFRQ, CNTPCT	
	EL0VCTEN	CNTPFRQ, CNTPVCT	

- a. If HCR\_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR\_EL2 using the same EC values as shown in the table.

### Traps to EL1 of EL0 accesses to Performance Monitors registers

PMUSERENR\_EL0.{ER, CR, SW, EN} trap EL0 accesses to the Performance Monitors registers to EL1. For each of these controls:

- 1** EL0 accesses are not trapped to EL1.
- 0** EL0 accesses are trapped to EL1.

For those Performance Monitors registers that more than one PMUSERENR\_EL0.{ER, CR, SW, EN} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.

Table D1-33 shows:

- The registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.
- How the exceptions are reported in ESR\_EL1.

**Table D1-33 Register accesses trapped to EL1 when disabled from EL0**

Traps from	Trap control	Registers	Access type	Syndrome reporting in ESR_EL1
AArch64 state	ER	PMXEVCNTR_EL0, PMEVCNTR<n>_EL0	R	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 <sup>a</sup>
		PMSELR_EL0	RW	
	CR	PMCCNTR_EL0	R	
	SW	PMSWINC_EL0	W	
	EN	PMCNTENSET_EL0, PMCNTENCLR_EL0, PMCR_EL0, PMOVSCLR_EL0, PMSWINC_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTYPER_EL0, PMXEVCNTR_EL0, PMOVSSET_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMCCFILTR_EL0.	RW	

**Table D1-33 Register accesses trapped to EL1 when disabled from EL0 (continued)**

Traps from	Trap control	Registers	Access type	Syndrome reporting in <a href="#">ESR_EL1</a>
AArch32 state	ER	<a href="#">PMXVCNTR</a> , <a href="#">PMEVCNTR&lt;n&gt;</a>	R	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 <sup>a</sup>
		<a href="#">PMSELR</a>	RW	
	CR	<a href="#">PMCCNTR</a> , accessed using an MRC	R	Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04 <sup>a</sup>

	SW	<a href="#">PMSWINC</a>	W	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 <sup>a</sup>
	EN	<a href="#">PMCNTENSET</a> , <a href="#">PMCNTENCLR</a> , <a href="#">PMCR</a> , <a href="#">PMOVS</a> , <a href="#">PMSWINC</a> , <a href="#">PMSELR</a> , <a href="#">PMCEID0</a> , <a href="#">PMCEID1</a> , <a href="#">PMCCNTR</a> , <a href="#">PMXEVTYPER</a> , <a href="#">PMXVCNTR</a> , <a href="#">PMOVSSET</a> , <a href="#">PMEVCNTR&lt;n&gt;</a> , <a href="#">PMEVTYPER&lt;n&gt;</a> , <a href="#">PMCCFILTR</a> , accessed using an MCR or MRC	RW	
	EN	<a href="#">PMCCNTR</a> , accessed using an MCRR or MRRC	RW	Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04 <sup>a</sup>

- a. If [HCR\\_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR\\_EL2](#) using the same EC values as shown in the table.

### D1.15.3 EL2 configurable controls

These controls are in [\\_EL2](#) System registers. The resulting exceptions might be taken from either Execution state. [SPSR\\_EL2.M\[4\]](#) indicates which Execution state the exception was taken from.

These controls are ignored in Secure state.

[Table D1-34](#) shows the [\\_EL2](#) System registers that contain these controls.

**Table D1-34 [\\_EL2](#) registers that contain instruction disables and trap controls**

Register name	Register description
<a href="#">HCR_EL2</a>	Hypervisor Configuration Register
<a href="#">HSTR_EL2</a>	Hypervisor System Trap Register
<a href="#">CPTR_EL2</a>	Architectural Feature Trap Register, EL2
<a href="#">MDCR_EL2</a>	Monitor Debug Configuration Register, EL2

[Table D1-35](#) on page D1-1852 summarizes the controls.

#### **Note**

- There are no instruction enables at EL2.
- For completeness, [Table D1-35](#) on page D1-1852 includes the routing control described in [Routing exceptions from Non-secure EL0 to EL2](#) on page D1-1827.

**Table D1-35 Instruction disables and trap controls provided by EL2**

Control	Control type <sup>a</sup>	Description
HCR_EL2.{TRVM, TVM}	T	<i>Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1853</i>
HCR_EL2.HCD	D	<i>Disabling Non-secure state execution of HVC instructions on page D1-1854</i>
HCR_EL2.TDZ	T	<i>Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions on page D1-1854</i>
HCR_EL2.TGE	R	<i>Routing exceptions from Non-secure EL0 to EL2 on page D1-1827</i>
HCR_EL2.TTLB	T	<i>Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions on page D1-1854</i>
HCR_EL2.{TSW, TPC, TPU}	T	<i>Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1855</i>
HCR_EL2.TACR	T	<i>Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1856</i>
HCR_EL2.TIDCP	T	<i>Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1857</i>
HCR_EL2.TSC	T	<i>Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1858</i>
HCR_EL2.{TID0, TID1, TID2, TID3}	T	<i>Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1858</i>
HCR_EL2.{TWI, TWE}	T	<i>Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1861</i>
CPTR_EL2.TCPAC	T	<i>Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR on page D1-1862</i>
CPTR_EL2.TFP	T	<i>General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers on page D1-1863</i>
CPTR_EL2.TTA	T	<i>Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1863</i>
HSTR_EL2.{T0-T3, T5-T13, T15}	T	<i>General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1864</i>
MDCR_EL2.{TDRA, TDOSA, TDA}	T	<i>Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers on page D1-1865</i>
CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}	T	<i>Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1867</i>
MDCR_EL2.{TPM, TPMCR}	T	<i>Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1868</i>

a. See Table D1-36 on page D1-1853.

**Table D1-36 Control types, for exceptions taken to EL1**

Abbreviation	Type	See
D	Disable	<a href="#">Instruction enables and instruction disables on page D1-1842</a>
R	Routing control	<a href="#">Routing exceptions from Non-secure EL0 to EL2 on page D1-1827</a>
T	Trap	<a href="#">Trap controls on page D1-1842</a>

Also see the following for more general information about traps to EL2:

- [Register access instructions on page D1-1843](#).
- For traps from an Exception level using AArch32:
  - [Instructions that fail their Condition code check on page G1-4429](#).
  - [Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-4429](#).

### Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers

**HCR\_EL2**.{TRVM, TVM} trap Non-secure EL1 accesses to the virtual memory control registers to EL2:

#### **HCR\_EL2**.TRVM, for read accesses:

- 1** Non-secure EL1 reads of the virtual memory control registers are trapped to EL2.
- 0** Non-secure EL1 reads of the virtual memory control registers are not trapped to EL2.

#### **HCR\_EL2**.TVM, for write access:

- 1** Non-secure EL1 writes to the virtual memory control registers are trapped to EL2.
- 0** Non-secure writes to the virtual memory control registers are not trapped to EL2.

Table D1-37 shows:

- The registers for which reads are trapped to EL2 when **HCR\_EL2**.TRVM is 1.
- The registers for which writes are trapped to EL2 when **HCR\_EL2**.TVM is 1.
- How the exceptions are reported in **ESR\_EL2**.

**Table D1-37 Register read and write accesses trapped when **HCR\_EL2**.{TRVM, TVM} are 1**

Traps from	Registers	Syndrome reporting in <b>ESR_EL2</b>
AArch64 state	<a href="#">SCTLR_EL1</a> , <a href="#">TTBR0_EL1</a> , <a href="#">TTBR1_EL1</a> , <a href="#">TCR_EL1</a> , <a href="#">ESR_EL1</a> , <a href="#">FAR_EL1</a> , <a href="#">AFSR0_EL1</a> , <a href="#">AFSR1_EL1</a> , <a href="#">MAIR_EL1</a> , <a href="#">AMAIR_EL1</a> , <a href="#">CONTEXTIDR_EL1</a> .	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.
AArch32 state	<a href="#">SCTLR</a> , <a href="#">TTBR0</a> , <a href="#">TTBR1</a> , <a href="#">TTBCR</a> , <a href="#">TTBCR2</a> , <a href="#">DACR</a> , <a href="#">DFSR</a> , <a href="#">IFSR</a> , <a href="#">DFAR</a> , <a href="#">IFAR</a> , <a href="#">ADFSR</a> , <a href="#">AIFSR</a> , <a href="#">PRRR</a> , <a href="#">NMRR</a> , <a href="#">MAIR0</a> , <a href="#">MAIR1</a> , <a href="#">AMAIR0</a> , <a href="#">AMAIR1</a> , <a href="#">CONTEXTIDR</a> .	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03. Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04.

#### ———— **Note** ————

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the Non-secure memory system. A hypervisor might use this trap as part of its virtualization of memory management.

## Disabling Non-secure state execution of HVC instructions

[HCR\\_EL2.HCD](#) disables Non-secure state execution of HVC instructions:

- 1** HVC instructions are UNDEFINED at EL2 and Non-secure EL1, and any resulting exception is taken from the current Exception level to the current Exception level.
- 0** HVC instruction execution is enabled at EL2 and Non-secure EL1.

### ———— Note ————

HVC instructions are always UNDEFINED at EL0.

[HCR\\_EL2.HCD](#) is only implemented if EL3 is not implemented. Otherwise, it is RES0.

[Table D1-38](#) shows how the exceptions are reported in [ESR\\_ELx](#):

**Table D1-38 Instruction disabled when [HCR\\_EL2.HCD](#) is 1**

Taken from	Disabled instruction	Syndrome reporting in <a href="#">ESR_ELx</a>
AArch64 state	HVC	Exception for an unknown reason, using EC value 0x00
AArch32 state	HVC	

## Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions

[HCR\\_EL2.TDZ](#) traps Non-secure EL0 and EL1 execution of DC ZVA instructions to EL2:

- 1** Any attempt to execute a DC ZVA instruction at Non-secure EL0 or EL1 is trapped to EL2. Reading the [DCZID\\_EL0](#) returns a value that indicates that DC ZVA instructions are not implemented.
- 0** Non-secure EL0 and EL1 execution of DC ZVA instructions is not trapped to EL2.

[Table D1-39](#) shows how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-39 Instruction trapped to EL1 when [HCR\\_EL2.TDZ](#) is 0**

Traps from	Trapped instruction	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">DC ZVA</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	n/a	n/a

## Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the system instruction encoding space includes TLB maintenance instructions.

[HCR\\_EL2.TTLB](#) traps Non-secure EL1 execution of TLB maintenance instructions to EL2:

- 1** Any attempt to execute a TLBI instruction at Non-secure EL1 is trapped to EL2.
- 0** Non-secure EL1 execution of TLBI instructions is not trapped to EL2.

Table D1-40 shows the instructions that are trapped, and how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-40 Instructions trapped to EL2 when [HCR\\_EL2.TTLB](#) is 1**

Traps from	Trapped instructions	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">TLBI VMALLE1IS</a> , <a href="#">TLBI VAE1IS</a> , <a href="#">TLBI ASIDE1IS</a> , <a href="#">TLBI VAAE1IS</a> , <a href="#">TLBI VALE1IS</a> , <a href="#">TLBI VAALE1IS</a> , <a href="#">TLBI VMALLE1</a> , <a href="#">TLBI VAE1</a> , <a href="#">TLBI ASIDE1</a> , <a href="#">TLBI VAAE1</a> , <a href="#">TLBI VALE1</a> , <a href="#">TLBI VAALE1</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<a href="#">TLBIALLIS</a> , <a href="#">TLBIMVAIS</a> , <a href="#">TLBIASIDIS</a> , <a href="#">TLBIMVAIS</a> , <a href="#">TLBIMVALIS</a> , <a href="#">TLBIMVAALIS</a> , <a href="#">ITLBIALL</a> , <a href="#">ITLBIMVA</a> , <a href="#">ITLBIASID</a> , <a href="#">DTLBIALL</a> , <a href="#">DTLBIMVA</a> , <a href="#">DTLBIASID</a> , <a href="#">TLBIALL</a> , <a href="#">TLBIMVA</a> , <a href="#">TLBIASID</a> , <a href="#">TLBIMVAA</a> , <a href="#">TLBIMVAL</a> , <a href="#">TLBIMVAAAL</a> .	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

———— **Note** —————

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see:

- [TLB maintenance instructions on page D4-2121](#), for the AArch64 state instructions.
- [The scope of TLB maintenance instructions on page G4-4641](#), for the AArch32 state instructions.

**Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions**

[HCR\\_EL2](#).{TSW, TPC, TPU} trap cache maintenance instructions to EL2 as follows:

- |          |   |
|----------|---|
| <b>0</b> | The control has no effect on the execution of cache maintenance instructions.   |
| <b>1</b> | Any attempt to execute a corresponding cache maintenance instruction at Non-secure EL1, or at Non-secure EL0 if permitted by <a href="#">SCTLR_EL1.UCI</a> , is trapped to EL2. |

**Table D1-41 Controls for trapping cache maintenance instructions to EL2**

Trap control	Trapped instructions
<a href="#">HCR_EL2.TSW</a>	Data or unified cache maintenance by set/way
<a href="#">HCR_EL2.TPC</a>	Data or unified cache maintenance to point of coherency
<a href="#">HCR_EL2.TPU</a>	Cache maintenance to point of unification

For:

- [HCR\\_EL2.TSW == 1](#), [Table D1-42 on page D1-1856](#) shows the instructions that are trapped, and how the exceptions are reported in [ESR\\_EL2](#).
- [HCR\\_EL2.TPC == 1](#), [Table D1-43 on page D1-1856](#) shows the instructions that are trapped, and how the exceptions are reported in [ESR\\_EL2](#).
- [HCR\\_EL2.TPU == 1](#), [Table D1-44 on page D1-1856](#) shows the instructions that are trapped, and how the exceptions are reported in [ESR\\_EL2](#).

**Table D1-42 Instructions trapped to EL2 when [HCR\\_EL2.TSW](#) is 1**

Traps from	Trapped instructions	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">DC ISW</a> , <a href="#">DC CSW</a> , <a href="#">DC CISW</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<a href="#">DCISW</a> , <a href="#">DCCSW</a> , <a href="#">DCCISW</a>	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

**Note**

These instructions are always UNDEFINED at EL0.

**Table D1-43 Instructions trapped to EL2 when [HCR\\_EL2.TPC](#) is 1**

Traps from	Trapped instructions	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">DC IVAC</a> , <a href="#">DC CVAC</a> , <a href="#">DC CIVAC</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<a href="#">DCIMVAC</a> , <a href="#">DCCIMVAC</a> , <a href="#">DCCMVAC</a>	Trapped MCR or MRC access, (coproc==0b1111) using EC value 0x03

**Note**

[DC IVAC](#) is always UNDEFINED at EL0 using AArch64.

[DCIMVAC](#), [DCCIMVAC](#), and [DCCMVAC](#) are always UNDEFINED at EL0 using AArch32.

**Table D1-44 Instructions trapped to EL2 when [HCR\\_EL2.TPU](#) is 1**

Traps from	Trapped instructions	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">IC IVAU</a> , <a href="#">IC IALLU</a> , <a href="#">IC IALLUIS</a> , <a href="#">DC CVAU</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<a href="#">ICIMVAU</a> , <a href="#">ICIALLU</a> , <a href="#">ICIALLUIS</a> , <a href="#">DCCMVAU</a>	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

**Note**

[IC IALLUIS](#) and [IC IALLU](#) are always UNDEFINED at EL0 using AArch64.

[ICIMVAU](#), [ICIALLU](#), [ICIALLUIS](#), and [DCCMVAU](#) are always UNDEFINED at EL0 using AArch32.

For more information about these instructions, see:

- [Cache maintenance instructions, and data cache zero](#) on page C5-318 for the AArch64 instructions.
- [Cache maintenance instructions, functional group](#) on page G4-4734 for the AArch32 instructions.

## Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register

[HCR\\_EL2.TACR](#) traps Non-secure EL1 accesses to the Auxiliary Control Registers to EL2:

- |          |  |
|----------|--|
| <b>1</b> | Non-secure EL1 accesses to the Auxiliary Control Registers are trapped to EL2.     |
| <b>0</b> | Non-secure EL1 accesses to the Auxiliary Control Registers are not trapped to EL2. |

Table D1-45 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-45 Register accesses trapped to EL2 when [HCR\\_EL2.TACR](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">ACTLR_EL1</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<a href="#">ACTLR</a> and, if implemented, <a href="#">ACTLR2</a> .	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

———— **Note** ————

- The [ACTLR\\_EL1](#), [ACTLR](#), and [ACTLR2](#) are not accessible at EL0.
- The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

**Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations**

The lockdown, DMA, and TCM features of the ARMv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

[HCR\\_EL2.TIDCP](#) traps the execution of System register access instructions that access these registers, as follows:

- 1** At Non-secure EL1, any attempt to execute a System register access instruction with a reserved register encoding is trapped to EL2.
- At Non-secure EL0, it is IMPLEMENTATION DEFINED whether attempts to execute System register access instructions with reserved register encodings are:
- Trapped to EL2.
  - UNDEFINED, and any resulting exception is taken to EL1.
- 0** Non-secure EL0 and EL1 System register access instructions with reserved register encodings are not trapped to EL2.

Table D1-46 shows the register encodings for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-46 Encodings trapped to EL2 when [HCR\\_EL2.TIDCP](#) is 1**

Traps from	Register encodings	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	Any access to any of the encodings described in <i>Reserved encodings for IMPLEMENTATION DEFINED registers</i> on page C5-334.	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	An access to any of the following encodings: <ul style="list-style-type: none"> <li>• CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}.</li> <li>• CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}.</li> <li>• CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}.</li> </ul>	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

———— **Note** ————

- ARM expects the trapping of Non-secure EL0 accesses to these functions to EL2 to be unusual, and used only when the hypervisor is virtualizing EL0 operation. ARM strongly recommends that unless the hypervisor must virtualize EL0 operation, a Non-secure EL0 access to any of these functions is UNDEFINED, as it would be if the implementation did not include EL2. The PE then takes any resulting exception to Non-secure EL1.

- The trapping of accesses to these registers from Non-secure EL1 is higher priority than an exception resulting from the register access being UNDEFINED.

## Traps to EL2 of Non-secure EL1 execution of SMC instructions

[HCR\\_EL2.TSC](#) traps Non-secure EL1 execution of SMC instructions to EL2:

**1** Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of [SCR\\_EL3.SMD](#).

**0** Non-secure EL1 execution of SMC instructions is not trapped to EL2.

If EL3 is not implemented, [HCR\\_EL2.TSC](#) is RES0.

[Table D1-47](#) shows how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-47 SMC Instruction trapped to EL2 when [HCR\\_EL2.TSC](#) is 1**

Traps from	Trapped instruction	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">SMC on page C6-827</a>	Trapped SMC instruction execution in AArch64 state, using EC value 0x17
AArch32 state	<a href="#">SMC on page F5-3429</a>	Trapped SMC instruction execution in AArch32 state, using EC value 0x13

In AArch32 state, the ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their Condition code check, in the same way as with traps on other conditional instructions.

For more information about SMC instructions, see [SMC on page C6-827](#).

### Note

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are UNDEFINED at EL0.
- [HCR\\_EL2.TSC](#) traps execution of the SMC instruction. It is not a routing control for the SMC exception. Trap exceptions and SMC exceptions have different preferred return addresses.

## Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers

Other than the [MIDR\\_EL1](#), [MPIDR\\_EL1](#), and [PMCR\\_EL0.N](#), the ID registers are divided into groups, with a trap control in the [HCR\\_EL2](#) for each group.

**Table D1-48 ID register groups**

Trap control	Register group
<a href="#">HCR_EL2.TID0</a>	<a href="#">ID group 0, Primary device identification registers on page D1-1859</a>
<a href="#">HCR_EL2.TID1</a>	<a href="#">ID group 1, Implementation identification registers on page D1-1860</a>
<a href="#">HCR_EL2.TID2</a>	<a href="#">ID group 2, Cache identification registers on page D1-1860</a>
<a href="#">HCR_EL2.TID3</a>	<a href="#">ID group 3, Detailed feature identification registers on page D1-1860</a>

These controls trap register accesses to EL2, as follows:

### [HCR\\_EL2.TID0](#)

**0** This control has no effect on Non-secure EL1 reads of the ID group 0 registers.

- 1 Any attempt at Non-secure EL0 or EL1 to read any register in ID group 0 is trapped to EL2.

#### HCR\_EL2.TID1

- 0 This control has no effect on Non-secure EL1 reads of the ID group 1 registers.  
1 Any attempt at Non-secure EL1 to read any register in ID group 1 is trapped to EL2.

#### HCR\_EL2.TID2

- 0 This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.  
1 Any attempt at Non-secure EL0 or EL1 to read any register in ID group 2, and any attempt at Non-secure EL0 or EL1 to write to the [CSSELR](#) or [CSSELR\\_EL1](#), is trapped to EL2.

#### HCR\_EL2.TID3

- 0 This control has no effect on Non-secure EL1 reads of the ID group 3 registers.  
1 Any attempt at Non-secure EL1 to read any register in ID group 3 is trapped to EL2.

For the [MIDR\\_EL1](#) and [MPIDR\\_EL1](#), and for [PMCR\\_EL0.N](#), the architecture provides read/write aliases. The original register becomes accessible only from EL2 or Secure state, and a Non-secure EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

**Table D1-49 ID register substitution**

Register	Original	Alias, EL2 using AArch64
Main ID	<a href="#">MIDR_EL1</a>	<a href="#">VPIDR_EL2</a>
Multiprocessor Affinity	<a href="#">MPIDR_EL1</a>	<a href="#">VMPIDR_EL2</a>
Performance Monitors Control Register	<a href="#">PMCR_EL0.N</a>	<a href="#">MDCR_EL2.HPMN</a>

Reads of the [MIDR\\_EL1](#), [MPIDR\\_EL1](#) or [PMCR\\_EL0.N](#) from EL2 or Secure state are unchanged by the implementation of EL2, and access the physical registers.

#### Note

- If the optional Performance Monitors Extension is not implemented, [MDCR\\_EL2.HPMN](#) is RES0 and [PMCR\\_EL0](#) is reserved.
- [MDCR\\_EL2.HPMN](#) also affects whether a Performance Monitors counter can be accessed from Non-secure EL0 or EL1. See the register description of [MDCR\\_EL2](#) for more information.
- [PMCR\\_EL0](#) contains other fields that identify the implementation. For more information about trapping accesses to the [PMCR\\_EL0](#), see *Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers* on page D1-1868.

#### ID group 0, Primary device identification registers

In:

- AArch64 state, there are no ID group 0 registers.
- AArch32 state, these registers identify some top-level implementation choices.

Table D1-50 shows the registers that are in ID group 0 for traps to EL2, and how the exceptions are reported in ESR\_EL2:

**Table D1-50 ID group 0 registers**

Traps from	Group 0 registers	Syndrome reporting in ESR_EL2
AArch64 state	n/a	n/a
AArch32 state	FPSID	Trapped VMRS System register access, using EC value 0x08
	JIDR	Trapped MRC System register access (coproc==0b1110), using EC value 0x05

———— **Note** —————

The FPSID is not accessible from EL0 using AArch32.

When the FPSID is accessible, a T32 or A32 VMRS FPSID, <Rt> instruction is permitted but is ignored. The execution of this VMRS instruction execution is not trapped by the ID group 0 trap.

**ID group 1, Implementation identification registers**

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table D1-51 shows the registers that are in ID group 1 for traps to EL2, and how the exceptions are reported in ESR\_EL2:

**Table D1-51 ID group 1 registers**

Traps from	Group 1 registers	Syndrome reporting in ESR_EL2
AArch64 state	REVIDR_EL1, AIDR_EL1	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	TCMTR, TLBTR, REVIDR, AIDR	Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03

**ID group 2, Cache identification registers**

These registers describe and control the cache implementation.

Table D1-52 shows the registers that are in ID group 2 for traps to EL2, and how the exceptions are reported in ESR\_EL2:

**Table D1-52 ID group 2 registers**

Traps from	Group 2 registers	Syndrome reporting in ESR_EL2
AArch64 state	CTR_EL0, CCSIDR_EL1, CLIDR_EL1, CSSELR_EL1	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	CTR, CCSIDR, CLIDR, CSSELR	Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03

**ID group 3, Detailed feature identification registers**

These registers provide detailed information about the features of the implementation.

### Note

In AArch32 state, these registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See [The CPUID identification scheme on page G4-4728](#).

Table D1-53 shows the registers that are in ID group 3 for traps to EL2, and how the exceptions are reported in ESR\_EL2:

**Table D1-53 ID group 3 registers**

Traps from	Group 3 registers	Syndrome reporting in ESR_EL2
AArch64 state	<p>ID_PFR0_EL1, ID_PFR1_EL1, ID_DFR0_EL1, ID_AFR0_EL1, ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, and ID_MMFR4_EL1, except that if ID_MMFR4_EL1 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether reads of the register are trapped.</p> <p>ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1.</p> <p>MVFR0_EL1, MVFR1_EL1, MVFR2_EL1.</p> <p>ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1, ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64MMFR2_EL1, ID_AA64AFR0_EL1, ID_AA64AFR1_EL1.</p> <p>It is IMPLEMENTATION DEFINED whether HCR_EL2.TID3 traps MRS accesses to registers in the following range that are not already mentioned in this table:</p> <ul style="list-style-type: none"> <li>Op0 == 3, CRn == c0, op1 == 0, CRm == {c2-c7}, op2 == {0-7}.</li> </ul>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<p>MVFR0, MVFR1, MVFR2.</p> <p>ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3 and, ID_MMFR4, except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether reads of the register are trapped.</p> <p>ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5.</p> <p>Any MRC access to any of the following encodings in the (coproc==0b1111) encoding space:</p> <ul style="list-style-type: none"> <li>CRn == c0, opc1 == 0, CRm == {c3-c7}, opc2 == {0, 1}.</li> <li>CRn == c0, opc1 == 0, CRm == c3, opc2 == 2.</li> <li>CRn == c0, opc1 == 0, CRm == c5, opc2 == {4, 5}.</li> </ul> <p>It is IMPLEMENTATION DEFINED whether HCR_EL2.TID3 traps MRC accesses to in the (coproc==0b1111) encoding space in the following range that are not already mentioned in this table:</p> <ul style="list-style-type: none"> <li>CRn == c0, opc1 == 0, CRm == {c2-c7}, opc2 == {0-7}.</li> </ul>	<p>Trapped VMRS System register access, using EC value 0x08</p> <p>Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03</p>

### Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions

HCR\_EL2.{TWE, TWI} trap Non-secure EL0 and EL1 execution of WFE and WFI instructions to EL2:

#### HCR\_EL2.TWE

- |   |  |
|---|--|
| 1 | Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state. |
| 0 | Non-secure EL0 or EL1 execution of WFE instructions is not trapped to EL2.   |

## HCR\_EL2.TWI

- 1** Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** Non-secure EL0 or EL1 execution of WFI instructions is not trapped to EL2.

Table D1-54 shows how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-54 Instructions trapped to EL2 when [HCR\\_EL2](#).{TWE, TWI} are 1**

Trap control	Traps from	Trapped instructions	Syndrome reporting in <a href="#">ESR_EL2</a>
<a href="#">HCR_EL2</a> .TWE	Both Execution states	WFE	Trapped WFI or WFE instruction, using EC value 0x01
<a href="#">HCR_EL2</a> .TWI		WFI	

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

### ———— Note ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait for Event mechanism and Send event](#) on page D1-1879.
- [Wait For Interrupt](#) on page D1-1882.

## Trapping to EL2 of Non-secure EL1 accesses to the CPACR\_EL1 or CPACR

[CPTR\\_EL2](#).TCPAC traps Non-secure EL1 accesses to the [CPACR\\_EL1](#) or [CPACR](#) to EL2:

- 1** Non-secure EL1 accesses to the [CPACR\\_EL1](#) or [CPACR](#) are trapped to EL2.
- 0** Non-secure EL1 accesses to the [CPACR\\_EL1](#) or [CPACR](#) are not trapped to EL2.

Table D1-55 shows how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-55 Register accesses trapped to EL2 when [CPTR\\_EL2](#).TCPAC is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">CPACR_EL1</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<a href="#">CPACR</a>	Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03

### ———— Note ————

- The [CPACR\\_EL1](#) or [CPACR](#) is not accessible at EL0.
- In ARMv7 and earlier versions of the ARM architecture, one function of the [CPACR](#) is as an ID register that identifies what coprocessor or conceptual coprocessor functionality is implemented. Legacy software might use this identification mechanism, and a hypervisor can use this trap to emulate this mechanism. For more information about this coprocessor model see [Background to the System register interface](#) on page G1-4410.

## General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers

[CPTR\\_EL2](#).TFP traps Non-secure accesses to SIMD and floating-point registers to EL2:

- 1. Any attempt at EL2, or Non-secure EL0 or EL1, to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL2.
- 0. Non-secure execution of instructions that access the SIMD or floating-point registers is not trapped to EL2.

[Table D1-56](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-56 Register accesses trapped to EL2 when [CPTR\\_EL2](#).TFP is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">FPCR</a> , <a href="#">FPSR</a> , <a href="#">FPEXC32_EL2</a> , and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See <i>The SIMD and floating-point registers, V0-V31</i> on page D1-1786.	Trapped access to a SIMD or floating-point register, resulting from <a href="#">CPACR_EL1</a> .FPEN or <a href="#">CPTR_ELx</a> .TFP, using EC value 0x07
AArch32 state	<a href="#">FPSID</a> , <a href="#">MVFR0</a> , <a href="#">MVFR1</a> , <a href="#">MVFR2</a> , <a href="#">FPSCR</a> , <a href="#">FPEXC</a> , and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See <i>Advanced SIMD and floating-point System registers</i> on page G1-4415.	Trapped access to a SIMD or floating-point register, resulting from <a href="#">CPACR_EL1</a> .FPEN or <a href="#">CPTR_ELx</a> .TFP, using EC value 0x07 <sup>a</sup>

- a. Permitted VMSR accesses to the [FPSID](#) are ignored, but for the purposes of this trap the architecture defines a VMSR access to the [FPSID](#) from EL1 or higher as an access to a SIMD and floating-point register.

## Traps to EL2 of Non-secure System register accesses to the trace registers

[CPTR\\_EL2](#).TTA traps System register accesses to the trace registers to EL2. These traps are from Non-secure state, so are from all of:

- EL2.
- Non-secure EL0 and EL1.

When [CPTR\\_EL2](#).TTA is:

- 1 Non-secure System register accesses to the trace registers are trapped to EL2.
- 0 Non-secure System register accesses to the trace registers are not trapped to EL2.

### Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than a [CPTR\\_EL2](#).TTA Trap exception.
- EL2 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see *Register access instructions* on page D1-1843.

Table D1-57 shows the registers for which accesses are trapped to EL2 when **CPTR\_EL2.TTA** is 1, and how the exceptions are reported in **ESR\_EL2**:

**Table D1-57 Register accesses trapped to EL2 when **CPTR\_EL2.TTA** is 1**

Traps from	Registers	Syndrome reporting in <b>ESR_EL2</b>
AArch64 state	All implemented trace registers	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.
AArch32 state	All implemented trace registers	<ul style="list-style-type: none"> <li>Trapped MCR or MRC System register access (coproc==0b1110), using EC value 0x05.</li> <li>Trapped MCRR or MRRC System register access (coproc==0b1110), using EC value 0x0C.</li> </ul>

### General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only

**HSTR\_EL2**.{T0-T3, T5-T13, T15} trap accesses to the AArch32 System registers in the coproc==0b1111 encoding space, by the register number, {c0-c3, c5-c13, c15} used for:

- The CRn argument used when accessing the register using an MCR or MRC instruction.
- The CRm argument used when accessing the register using an MCRR or MRRC instruction.

These traps are from AArch32 state only. They are from both:

- Non-secure EL1 using AArch32.
- Non-secure EL0 using AArch32.

When an **HSTR\_EL2.Tx** trap control is:

- 1** Any AArch32 state Non-secure EL1 or EL0 access to the corresponding register is trapped to EL2.
- 0** AArch32 state Non-secure EL1 or EL0 accesses to the corresponding register are not trapped to EL2.

Table D1-58 shows the accesses that are trapped, and how the exceptions are reported in **ESR\_EL2**:

**Table D1-58 Accesses trapped to EL2 when an **HSTR\_EL2.Tx** trap is enabled**

Traps from	Trapped accesses	Syndrome reporting in <b>ESR_EL2</b>
AArch64 state	n/a	n/a
AArch32 state	MCR and MRC instructions, where CRn in the instruction identifies the trapped encodings in the (coproc==0b1111) encoding space	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03
	MCRR and MRRC instructions, where CRm in the instruction identifies the trapped encodings in the (coproc==0b1111) encoding space	Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04

#### ————— **Note** —————

**HSTR\_EL2**[4, 14] is reserved, RES0. Although the Generic Timer AArch32 System registers are implemented in the coproc==0b1111 encoding space and accessed using a CRn or CRm value of c14, EL2 does not provide a trap on accesses to the Generic Timer System registers.

### System registers in the (coproc==0b1111) encoding space with IMPLEMENTATION DEFINED access permission from EL0

For an AArch32 System register in the (coproc==0b1111) encoding space, that is accessed using a CRn or CRm value that can be trapped by a [HSTR\\_EL2](#).Tn control, if an access to the register from EL0 is UNDEFINED when the value of the corresponding [HSTR\\_EL2](#).Tn trap control is 0, then when that [HSTR\\_EL2](#).Tn trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure EL0 using AArch32:

- Generates a Trap exception that is taken to EL2.
- Is UNDEFINED and generates an exception that is taken to Non-secure EL1.

If the instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1, and Non-secure EL1 is using AArch64, the exception is reported in [ESR\\_EL1](#) as an exception for an unknown reason, using EC value 0x00.

#### ————— Note —————

ARM expects that trapping to EL2 of Non-secure EL0 accesses to AArch32 System register in the (coproc==0b1111) encoding space will be unusual, and used only when the hypervisor must virtualize EL0 operation. ARM recommends that, whenever possible, Non-secure EL0 accesses to the System registers behave as they would if the implementation did not include EL2. This means that, if the architecture does not support the Non-secure EL0 access, then the register access instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1.

### Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers

[MDCR\\_EL2](#).{TDRA, TDOSA, TDA} trap Non-secure System register accesses to the debug registers to EL2, as follows:

- [MDCR\\_EL2](#).{TDRA, TDA} trap Non-secure EL0 and EL1 accesses.
- [MDCR\\_EL2](#).TDOSA traps Non-secure EL1 accesses.

#### ————— Note —————

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2. See [Register access instructions on page D1-1843](#).

[Table D1-59](#) shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in [ESR\\_EL2](#):

**Table D1-59 Traps of Non-secure EL0 and EL1 accesses to debug registers**

Trap control	Subsection
<a href="#">MDCR_EL2</a> .TDRA	<a href="#">Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers</a>
<a href="#">MDCR_EL2</a> .TDOSA	<a href="#">Trapping System register accesses to powerdown debug registers to EL2 on page D1-1866</a>
<a href="#">MDCR_EL2</a> .TDA	<a href="#">Trapping general System register accesses to debug registers to EL2 on page D1-1866</a>

### Trapping System register accesses to Debug ROM registers to EL2

[MDCR\\_EL2](#).TDRA traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to EL2:

- |          |  |
|----------|--|
| <b>1</b> | Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2.     |
| <b>0</b> | Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are not trapped to EL2. |

This trap applies to Non-secure EL0 only if it is using AArch32.

Table D1-60 shows the register accesses that are trapped, and how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-60 Register accesses trapped to EL2 when [MDCR\\_EL2.TDRA](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">MDRAR_EL1</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.
AArch32 state	<a href="#">DBGDRAR</a> , <a href="#">DBGDSAR</a>	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.</li> </ul>

If [MDCR\\_EL2.TDE](#) or [HCR\\_EL2.TGE](#) is 1, behavior is as if [MDCR\\_EL2.TDRA](#) is 1 other than for the purpose of a direct read.

#### **Trapping System register accesses to powerdown debug registers to EL2**

[MDCR\\_EL2.TDOSA](#) traps Non-secure EL1 System register accesses to the powerdown debug registers to EL2:

- 1 . Non-secure EL1 System register accesses to the powerdown debug registers are trapped to EL2.
- 0 . Non-secure EL1 System register accesses to the powerdown debug registers are not trapped to EL2.

Table D1-61 shows the register accesses that are trapped, and how the exceptions are reported in [ESR\\_EL2](#):

**Table D1-61 Register accesses trapped to EL2 when [MDCR\\_EL2.TDOSA](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">OSLSR_EL1</a> , <a href="#">OSLSR_EL1</a> , <a href="#">OSDLR_EL1</a> , <a href="#">DBGPRCR_EL1</a> . Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by <a href="#">MDCR_EL2.TDOSA</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.
AArch32 state	<a href="#">DBGOSLSR</a> , <a href="#">DBGOSLAR</a> , <a href="#">DBGOSDLR</a> , <a href="#">DBGPRCR</a> . Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by <a href="#">HDCR.TDOSA</a>	Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.

#### **———— Note ————**

These registers are not accessible at EL0.

If [MDCR\\_EL2.TDE](#) or [HCR\\_EL2.TGE](#) is 1, behavior is as if [MDCR\\_EL2.TDOSA](#) is 1 other than for the purpose of a direct read.

#### **Trapping general System register accesses to debug registers to EL2**

[MDCR\\_EL2.TDA](#) traps Non-secure EL0 and EL1 System register accesses to those debug System registers that are not mentioned in either of the following:

- [Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers](#) on page D1-1865.
- [Trapping System register accesses to powerdown debug registers to EL2](#).

This means that [MDCR\\_EL2.TDA](#) traps Non-secure EL0 and EL1 System register accesses to all debug System registers to EL2, except the following:

- Any access from:
  - AArch64 state to the [MDRAR\\_EL1](#).
  - AArch32 state to the [DBGDRAR](#) or [DBGDSAR](#).

**MDCR\_EL2**.TDRA traps these accesses.

- Any access from:
  - AArch64 state to the **OSLAR\_EL1**, **OSLSR\_EL1**, **OSDLR\_EL1** or **DBGPRCR\_EL1**.
  - AArch32 state to the **DBGOSLSR**, **DBGOSLAR**, **OSDLR\_EL1** or **DBGPRCR**.

**MDCR\_EL2**.TDOSA traps these accesses.

When the PE is in Debug state, **MDCR\_EL2**.TDA does not trap any access from:

- AArch32 state to **DBGDTRRXint** and **DBGDTRTXint**.
- AArch64 state to **DBGDTR\_EL0**, **DBGDTRRX\_EL0**, and **DBGDTRTX\_EL0**.

When **MDCR\_EL2**.TDA is:

- |          |   |
|----------|---|
| <b>1</b> | Non-secure EL0 or EL1 System register accesses to any of the registers shown in Table D1-62 are trapped to EL2. |
| <b>0</b> | Non-secure EL0 or EL1 System register accesses to the registers shown in Table D1-62 are not trapped to EL2.    |

Table D1-62 shows how the exceptions are reported in **ESR\_EL2**:

**Table D1-62 Accesses trapped to EL2 when **MDCR\_EL2**.TDA is 1**

Traps from	Trapped accesses	Syndrome reporting in <b>ESR_EL2</b>
AArch64 state	Accesses to the <b>MDCCSR_EL0</b> , <b>MDCCINT_EL1</b> , <b>DBGDTR_EL0</b> , <b>DBGDTRRX_EL0</b> , <b>DBGDTRTX_EL0</b> , <b>OSDTRRX_EL1</b> , <b>MDSCR_EL1</b> , <b>OSDTRTX_EL1</b> , <b>OSECCR_EL1</b> , <b>DBGBVR&lt;n&gt;_EL1</b> , <b>DBGBCR&lt;n&gt;_EL1</b> , <b>DBGWVR&lt;n&gt;_EL1</b> , <b>DBGWCR&lt;n&gt;_EL1</b> , <b>DBGCLAIMSET_EL1</b> , <b>DBGCLAIMCLR_EL1</b> , and <b>DBGAUTHSTATUS_EL1</b> .	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	Accesses to the <b>DBGDIDR</b> , <b>DBGDSCRint</b> , <b>DBGDCCINT</b> , <b>DBGDTRRXint</b> , <b>DBGDTRTXint</b> , <b>DBGWFAR</b> , <b>DBGVCR</b> , <b>DBGDSCRExt</b> , <b>DBGDTRTXext</b> , <b>DBGDTRRXext</b> , <b>DBGBVR&lt;n&gt;</b> , <b>DBGBCR&lt;n&gt;</b> , <b>DBGBXVR&lt;n&gt;</b> , <b>DBGWCR&lt;n&gt;</b> , <b>DBGWVR&lt;n&gt;</b> , <b>DBGCLAIMSET</b> , <b>DBGCLAIMCLR</b> , <b>DBGAUTHSTATUS</b> , <b>DBGDEVID</b> , <b>DBGDEVID1</b> , <b>DBGDEVID2</b> , and <b>DBGOSECCR</b> .	For accesses using MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05
	STC accesses to <b>DBGDTRRXint</b> . LDC accesses to <b>DBGDTRTXint</b> .	Trapped LDC or STC access, using EC value 0x06

If **MDCR\_EL2**.TDE or **HCR\_EL2**.TGE is 1, behavior is as if **MDCR\_EL2**.TDA is 1 other than for the purpose of a direct read.

### Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers

**CNTHCTL\_EL2**.{EL1PCEN, EL1PCTEN} trap Non-secure EL0 and EL1 accesses to the Generic Timer registers to EL2, as follows:

- CNTHCTL\_EL2**.EL1PCEN traps Non-secure EL0 and EL1 accesses to the physical timer registers.
- CNTHCTL\_EL2**.EL1PCTEN traps Non-secure EL0 and EL1 accesses to the physical counter register.

For each of these controls:

- |          |   |
|----------|---|
| <b>1</b> | Non-secure EL0 and EL1 accesses are not trapped to EL2. |
| <b>0</b> | Non-secure EL0 and EL1 accesses are trapped to EL2.     |

Table D1-63 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL2](#).

**Table D1-63 Register accesses trapped to EL2 by [CNTHTL\\_EL2](#) trap controls**

Traps from	Trap control	Registers	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	EL1PCEN	<a href="#">CNTP_CTL_EL0</a> , <a href="#">CNTP_CVAL_EL0</a> , <a href="#">CNTP_TVAL_EL0</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
	EL1PCTEN	<a href="#">CNTPCT_EL0</a>	
AArch32 state	EL1PCEN	<a href="#">CNTP_CTL</a> , <a href="#">CNTP_CVAL</a> , <a href="#">CNTP_TVAL</a>	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04</li> </ul>
	EL1PCTEN	<a href="#">CNTPCT</a>	Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04

### Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers

[MDCR\\_EL2](#).{TPM, TPMCR} trap Non-secure EL0 and EL1 accesses to the Performance Monitors registers to EL2:

#### [MDCR\\_EL2](#).TPM

- |          |   |
|----------|---|
| <b>1</b> | Non-secure EL0 and EL1 accesses to the Performance Monitors registers are trapped to EL2.     |
| <b>0</b> | Non-secure EL0 and EL1 accesses to the Performance Monitors registers are not trapped to EL2. |

#### [MDCR\\_EL2](#).TPMCR

- |          |   |
|----------|---|
| <b>1</b> | Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers are trapped to EL2.     |
| <b>0</b> | Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers are not trapped to EL2. |

#### ———— **Note** ————

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

For:

- [MDCR\\_EL2](#).TPM == 1, [Table D1-64 on page D1-1869](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL2](#).

- [MDCR\\_EL2.TPMCR](#) == 1, [Table D1-65](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL2](#).

**Table D1-64 Register accesses trapped to EL2 when [MDCR\\_EL2.TPM](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">PMCR_EL0</a> , <a href="#">PMCNTENSET_EL0</a> , <a href="#">PMCNTENCLR_EL0</a> , <a href="#">PMOVSCLR_EL0</a> , <a href="#">PMSWINC_EL0</a> , <a href="#">PMSELR_EL0</a> , <a href="#">PMCEID0_EL0</a> , <a href="#">PMCEID1_EL0</a> , <a href="#">PMCCNTR_EL0</a> , <a href="#">PMXEVTYPER_EL0</a> , <a href="#">PMXEVCNTR_EL0</a> , <a href="#">PMUSERENR_EL0</a> , <a href="#">PMINTENSET_EL1</a> , <a href="#">PMINTENCLR_EL1</a> , <a href="#">PMOVSSET_EL0</a> , <a href="#">PMEVCNTR&lt;n&gt;_EL0</a> , <a href="#">PMEVTYPER&lt;n&gt;_EL0</a> , <a href="#">PMCCFILTR_EL0</a> .	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18

For accesses using: <ul style="list-style-type: none"> <li>• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</li> <li>• MCRR or MRRC instructions, trapped MCRR or MRRC access, (coproc==0b1111) using EC value 0x04</li> </ul>

**Table D1-65 Register accesses trapped to EL2 when [MDCR\\_EL2.TPMCR](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL2</a>
AArch64 state	<a href="#">PMCR_EL0</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<a href="#">PMCR</a>	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

———— **Note** —————

[MDCR\\_EL2.HPMN](#) affects whether a counter can be accessed from Non-secure EL0 or EL1. See the register description of [MDCR\\_EL2](#) for more information.

## D1.15.4 EL3 configurable controls

These controls are in \_EL3 System registers. The resulting exceptions might be taken from either Execution state. [SPSR\\_EL3.M\[4\]](#) indicates which Execution state the exception was taken from.

[Table D1-66](#) shows the \_EL3 System registers that contain these controls.

**Table D1-66 \_EL3 registers that contain instruction enables and disables, and trap controls**

Register description	Register name
Secure Configuration Register	<a href="#">SCR_EL3</a>
Architectural Feature Trap Register, EL3	<a href="#">CPTR_EL3</a>
Monitor Debug Configuration Register, EL3	<a href="#">MDCR_EL3</a>

Table D1-67 summarizes the controls.

**Table D1-67 Instruction enables and disables, and trap controls, provided by EL3**

Control	Control type <sup>a</sup>	Description
SCR_EL3.{TWE, TWI}	T	<i>Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1871</i>
SCR_EL3.ST	T	<i>Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers on page D1-1872</i>
SCR_EL3.HCE	E	<i>Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions on page D1-1872</i>
SCR_EL3.SMD	D	<i>Disabling EL3, EL2, and EL1 execution of SMC instructions on page D1-1873</i>
CPTR_EL3.TCPAC	T	<i>Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-1873</i>
CPTR_EL3.TTA	T	<i>Traps to EL3 of all System register accesses to the trace registers on page D1-1874</i>
CPTR_EL3.TFP	T	<i>Traps to EL3 of all accesses to the SIMD and floating-point registers on page D1-1874</i>
MDCR_EL3.{TDOSA, TDA}	T	<i>Traps to EL3 of EL2, EL1, and EL0 System register accesses to debug registers on page D1-1875</i>
MDCR_EL3.TPM	T	<i>Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1877</i>

a. See Table D1-68.

**Table D1-68 Control types, for exceptions taken to EL1**

Abbreviation	Type	See
D	Disable	<i>Instruction enables and instruction disables on page D1-1842</i>
E	Enable	<i>Instruction enables and instruction disables on page D1-1842</i>
T	Trap	<i>Trap controls on page D1-1842</i>

Also see the following for more general information about traps to EL3:

- *Register access instructions on page D1-1843.*
- *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32.*

### Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32

If EL1 is using AArch32, all of the following are trapped to EL3:

- Secure EL1 reads and writes to any of the [SCR](#), [NSACR](#), [MVBAR](#) or [SDCR](#).
- Any attempt at Secure EL1 to execute any of the following:
  - [ATS12NSO\\*\\*](#) instructions.
  - SRS instructions that use the R13\_mon banked register.
  - MRS or MSR instructions that access any of the SPSR\_mon, R13\_mon or R14\_mon banked registers.

In addition, if EL1 is using AArch32:

- Secure EL1 write accesses to the [CNTFRQ](#) register are UNDEFINED. They are not trapped to EL3.

- Any attempt at Secure EL1 to change the PE mode to Monitor mode, by using a CPS or an MSR instruction, or by performing an exception return, is treated as an illegal change of the **CPSR.M** field. See *Illegal changes to PSTATE.M* on page G1-4336.

Table D1-69 shows the accesses that are trapped to EL3, and how the exceptions are reported in **ESR\_EL3**.

**Table D1-69 Accesses trapped to EL3 from Secure EL1 using AArch32**

Taken from	Trapped instructions, or trapped accesses	Syndrome reporting in <b>ESR_EL3</b>
Secure EL1 using AArch32	Reads and writes to any of the <b>SCR</b> , <b>NSACR</b> , <b>MVBAR</b> or <b>SDCR</b> <b>ATS12NSO**</b> instructions	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03
	SRS instructions that use the R13_mon banked register	Exception for an unknown reason, using EC value 0x00
	MRS or MSR instructions that accesses any of the SPSR_mon, R13_mon or R14_mon banked registers	

———— **Note** —————

- Reads of the **NSACR** from either Non-secure EL1 using AArch32 or Non-secure EL2 using AArch32 return the value 0x00000C00. See *Restricted access System registers* on page G4-4694.
- These operations are not available at EL0.

**Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions**

**SCR\_EL3**.{TWE, TWI} trap EL2, EL1, and EL0 execution of WFE and WFI instructions to EL3:

**SCR\_EL3.TWE**

- 1** Any attempt to execute a WFE instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** EL2, EL1, and EL0 execution of WFE instructions is not trapped to EL3.

**SCR\_EL3.TWI**

- 1** Any attempt to execute a WFI instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** EL2, EL1, and EL0 execution of WFI instructions is not trapped.

For EL0 and EL1, these traps apply to WFE and WFI execution in both Security states.

Table D1-70 shows how the exceptions are reported in **ESR\_EL3**.

**Table D1-70 Instructions trapped to EL3 when **SCR\_EL3**.{TWE, TWI} are 1**

Trap control	Traps from	Trapped instructions	Syndrome reporting in <b>ESR_EL3</b>
<b>SCR_EL3.TWE</b>	Both Execution states	WFE	Trapped WFI or WFE instruction, using EC value 0x01
<b>SCR_EL3.TWI</b>		WFI	

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

### Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait for Event mechanism and Send event on page D1-1879.](#)
- [Wait For Interrupt on page D1-1882.](#)

## Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers

[SCR\\_EL3.ST](#) traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3:

- 1** Secure EL1 accesses to the Counter-timer Physical Secure timer registers are not trapped to EL3.
- 0** Secure EL1 accesses to the Counter-timer Physical Secure timer registers are trapped to EL3.

### Note

Accesses to the Counter-timer Physical Secure timer registers are always enabled at EL3.

[Table D1-71](#) shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in [ESR\\_EL3](#).

**Table D1-71 Register accesses trapped to EL3 when [SCR\\_EL3.ST](#) is 0**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL3</a>
AArch64 state	<a href="#">CNTPS_TVAL_EL1</a> <a href="#">CNTPS_CTL_EL1</a> <a href="#">CNTPS_CVAL_EL1</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	n/a	n/a

### Note

These registers are not accessible at EL0.

## Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions

[SCR\\_EL3.HCE](#) enables HVC instruction execution at EL1 and above:

- 1** HVC instruction execution is enabled at EL1 and above.
- 0** HVC instructions are UNDEFINED at EL1, EL2, and EL3, and any resulting exception is taken from the current Exception level to the current Exception level.

For EL1, this enable control applies to HVC instructions in Non-secure state only.

If EL2 is not implemented, this bit is RES0.

### Note

HVC instructions are always UNDEFINED at EL0.

Table D1-72 shows how the exceptions are reported in [ESR\\_ELx](#):

**Table D1-72 Instruction disabled when [SCR\\_EL3.HCE](#) is 0**

Taken from	Disabled instruction	Syndrome reporting in <a href="#">ESR_ELx</a>
AArch64 state	HVC	Exception for an unknown reason, using EC value 0x00
AArch32 state		

### Disabling EL3, EL2, and EL1 execution of SMC instructions

[SCR\\_EL3.SMD](#) disables SMC instruction execution at EL1 and above:

- 1** SMC instructions are UNDEFINED at EL1 and above, and any resulting exception is taken from the current Exception level to the current Exception level.
- 0** SMC instruction execution is enabled at EL1 and above.

For EL1, this disable control applies to SMC instructions in both Security states.

#### **Note**

SMC instructions are always UNDEFINED at EL0.

Table D1-73 shows how the exceptions are reported in [ESR\\_ELx](#):

**Table D1-73 Exceptions generated when [SCR\\_EL3.SMD](#) is 1**

Taken from	Disabled Instruction	Syndrome reporting in <a href="#">ESR_ELx</a>
AArch64 state	<a href="#">SMC</a>	Exception for an unknown reason, using EC value 0x00
AArch32 state		

#### **Note**

If [HCR\\_EL2.TSC](#) or [HCR.TSC](#) traps attempted EL1 execution of SMC instructions to EL2, that trap has priority over this disable.

### Trapping to EL3 of EL2 accesses to the [CPTR\\_EL2](#) or [HCPTR](#), and EL2 and EL1 accesses to the [CPACR\\_EL1](#) or [CPACR](#)

[CPTR\\_EL3.TCPAC](#) traps all of the following to EL3:

- EL2 accesses to the [CPTR\\_EL2](#) or [HCPTR](#).
- EL2 and EL1 accesses to the [CPACR\\_EL1](#) or [CPACR](#).

When [CPTR\\_EL3.TCPAC](#) is:

- 1** EL2 accesses to the [CPTR\\_EL2](#) or [HCPTR](#), and EL2 and EL1 accesses to the [CPACR\\_EL1](#) or [CPACR](#), are trapped to EL3.
- 0** EL2 accesses to the [CPTR\\_EL2](#) or [HCPTR](#), and EL2 and EL1 accesses to the [CPACR\\_EL1](#) or [CPACR](#), are not trapped to EL3.

For EL1, this trap control applies to accesses from both Security states.

Table D1-74 shows how the exceptions are reported in [ESR\\_EL3](#).

**Table D1-74 Register accesses trapped to EL3 when [CPTR\\_EL3.TCPAC](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL3</a>
AArch64 state	<a href="#">CPTR_EL2</a> <a href="#">CPACR_EL1</a>	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<a href="#">HCPTR</a> <a href="#">CPACR</a>	Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03

### Traps to EL3 of all System register accesses to the trace registers

[CPTR\\_EL3.TTA](#) traps System register accesses to the trace registers, from all Exception levels, to EL3:

- 1** All System register accesses to the trace registers are trapped to EL3.  
**0** System register accesses to the trace registers are not trapped to EL3.

#### ———— Note ————

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than a [CPTR\\_EL3.TTA](#) Trap exception.
- EL3 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see [Register access instructions on page D1-1843](#).

For EL0 and EL1, this trap control applies to accesses from both Security states.

[Table D1-75](#) shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in [ESR\\_EL3](#).

**Table D1-75 Register accesses trapped to EL3 when [CPTR\\_EL3.TTA](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL3</a>
AArch64 state	All implemented trace registers	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	All implemented trace registers	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.</li> </ul>

### Traps to EL3 of all accesses to the SIMD and floating-point registers

[CPTR\\_EL3.TFP](#) traps all accesses to SIMD and floating-point registers, from all Exception levels, to EL3:

- 1** Any attempt at any Exception level to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL3  
**0** Execution of instructions that access the SIMD or floating-point registers is not trapped to EL3.

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-76 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in [ESR\\_EL3](#).

**Table D1-76 Register accesses trapped to EL3 when [CPTR\\_EL3.TFP](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL3</a>
AArch64 state	<a href="#">FPCR</a> , <a href="#">FPSR</a> , <a href="#">FPEXC32_EL2</a> , and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See <i>The SIMD and floating-point registers, V0-V31</i> on page D1-1786.	Trapped access to a SIMD or floating-point register, resulting from <a href="#">CPACR_EL1.FPEN</a> or <a href="#">CPTR_ELx.TFP</a> , using EC value 0x07
AArch32 state	<a href="#">FPSID</a> , <a href="#">MVFR0</a> , <a href="#">MVFR1</a> , <a href="#">MVFR2</a> , <a href="#">FPSCR</a> , <a href="#">FPEXC</a> , and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See <i>Advanced SIMD and floating-point System registers</i> on page G1-4415.	Trapped access to a SIMD or floating-point register, resulting from <a href="#">CPACR_EL1.FPEN</a> or <a href="#">CPTR_ELx.TFP</a> , using EC value 0x07 <sup>a</sup>

- a. Permitted VMSR accesses to the [FPSID](#) are ignored, but for the purposes of this trap the architecture defines a VMSR access to the [FPSID](#) from EL1 or higher is an access to a SIMD and floating-point register.

**Note**

- [FPEXC32\\_EL2](#) is not accessible from EL0 using AArch64.
- [FPSID](#), [MVFR0](#), [MVFR1](#), and [FPEXC](#) are not accessible from EL0 using AArch32.

**Traps to EL3 of EL2, EL1, and EL0 System register accesses to debug registers**

[MDCR\\_EL3](#).{TDOSA, TDA} trap EL2, EL1, and EL0 System register accesses to the debug registers to EL3, from both Security states.

**Note**

EL3 does not provide traps on debug register accesses through the Memory-mapped or External debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL3, no side-effects occur before the exception is taken to EL3. See *Register access instructions* on page D1-1843.

Table D1-77 shows the subsections that list the accesses trapped.

**Table D1-77 Traps of EL2, EL1, and EL0 accesses to debug registers**

Trap control	Subsection
<a href="#">MDCR_EL3</a> .TDOSA	<i>Trapping System register accesses to powerdown debug registers to EL3</i>
<a href="#">MDCR_EL3</a> .TDA	<i>Trapping general System register accesses to debug registers to EL3 on page D1-1876</i>

**Trapping System register accesses to powerdown debug registers to EL3**

[MDCR\\_EL3](#).TDOSA traps EL2 and EL1 accesses to the powerdown debug registers to EL3:

- 1** EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3.  
**0** EL2 and EL1 System register accesses to the powerdown debug registers are not trapped to EL3.

For EL1, this trap control applies to accesses from both Security states.

Table D1-78 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL3](#).

**Table D1-78 Register accesses trapped to EL3 when [MDCR\\_EL3.TDOSA](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL3</a>
AArch64 state	<a href="#">OSLAR_EL1</a> , <a href="#">OSLSR_EL1</a> , <a href="#">OSDLR_EL1</a> , <a href="#">DBGPRCR_EL1</a> . Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by <a href="#">MDCR_EL3.TDOSA</a> .	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.
AArch32 state	<a href="#">DBGOSLSR</a> , <a href="#">DBGOSLAR</a> , <a href="#">DBGOSDLR</a> , <a href="#">DBGPRCR</a> .	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.</li> </ul>

———— **Note** ————

These registers are not accessible at EL0.

**Trapping general System register accesses to debug registers to EL3**

[MDCR\\_EL3.TDA](#) traps EL2, EL1, and EL0 System register accesses to the debug System registers that are not mentioned in *Trapping System register accesses to powerdown debug registers to EL3* on page D1-1875.

This means that [MDCR\\_EL3.TDA](#) traps EL2, EL1, and EL0 System register accesses to all debug System registers, except the following:

- Accesses from AArch64 state to the [OSLAR\\_EL1](#), [OSLSR\\_EL1](#), [OSDLR\\_EL1](#) or [DBGPRCR\\_EL1](#).
- Accesses from AArch32 state to the [DBGOSLSR](#), [DBGOSLAR](#), [OSDLR\\_EL1](#) or [DBGPRCR](#).

When [MDCR\\_EL3.TDA](#) is:

- |          |   |
|----------|---|
| <b>1</b> | EL2, EL1, and EL0 System register accesses to any of the registers shown in <a href="#">Table D1-79 on page D1-1877</a> are trapped to EL3. |
| <b>0</b> | EL2, EL1, and EL0 System register accesses to the registers shown in <a href="#">Table D1-79 on page D1-1877</a> are not trapped to EL3.    |

For EL0 and EL1, this trap control applies to accesses from both Security states.

When the PE is in Debug state, [MDCR\\_EL3.TDA](#) does not trap any access from:

- AArch32 state to [DBGDTRRXint](#) and [DBGDTRTXint](#).
- AArch64 state to [DBGDTR\\_EL0](#), [DBGDTRRX\\_EL0](#), and [DBGDTRTX\\_EL0](#).

Table D1-79 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL3](#).

**Table D1-79 Accesses trapped to EL3 when [MDCR\\_EL3.TDA](#) is 1**

Traps from	Trapped accesses	Syndrome reporting in <a href="#">ESR_EL3</a>
AArch64 state	Accesses to the <a href="#">MDCR_EL2</a> , <a href="#">MDRAR_EL1</a> , <a href="#">MDCCSR_EL0</a> , <a href="#">MDCCINT_EL1</a> , <a href="#">DBGDTR_EL0</a> , <a href="#">DBGDTRRX_EL0</a> , <a href="#">DBGDTRTX_EL0</a> , <a href="#">OSDTRRX_EL1</a> , <a href="#">MDSCR_EL1</a> , <a href="#">OSDTRTX_EL1</a> , <a href="#">OSECCR_EL1</a> , <a href="#">DBGBVR&lt;n&gt;_EL1</a> , <a href="#">DBGBCR&lt;n&gt;_EL1</a> , <a href="#">DBGWVR&lt;n&gt;_EL1</a> , <a href="#">DBGWCR&lt;n&gt;_EL1</a> , <a href="#">DBGCLAIMSET_EL1</a> , <a href="#">DBGCLAIMCLR_EL1</a> , and <a href="#">DBGAUTHSTATUS_EL1</a> .	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	Accesses to the <a href="#">HDCR</a> , <a href="#">DBGDRAR</a> , <a href="#">DBGDSAR</a> , <a href="#">DBGDIDR</a> , <a href="#">DBGDSCRint</a> , <a href="#">DBGDCCINT</a> , <a href="#">DBGDTRRXint</a> , <a href="#">DBGDTRTXint</a> , <a href="#">DBGWFAR</a> , <a href="#">DBGVCR</a> , <a href="#">DBGDSCRext</a> , <a href="#">DBGDTRTXext</a> , <a href="#">DBGDTRRXext</a> , <a href="#">DBGBVR&lt;n&gt;</a> , <a href="#">DBGBCR&lt;n&gt;</a> , <a href="#">DBGBXVR&lt;n&gt;</a> , <a href="#">DBGWCR&lt;n&gt;</a> , <a href="#">DBGWVR&lt;n&gt;</a> , <a href="#">DBGCLAIMSET</a> , <a href="#">DBGCLAIMCLR</a> , <a href="#">DBGAUTHSTATUS</a> , <a href="#">DBGDEVID</a> , <a href="#">DBGDEVID1</a> , <a href="#">DBGDEVID2</a> , and <a href="#">DBGOSECCR</a> .	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</li> <li>MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.</li> </ul>
	STC accesses to <a href="#">DBGDTRRXint</a> .	LDC or STC, trapped LDC or STC access, using EC value 0x06
	LDC accesses to <a href="#">DBGDTRTXint</a> .	

### Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers

[MDCR\\_EL3.TPM](#) traps EL2, EL1, and EL0 accesses to the Performance Monitors registers to EL3:

- |          |  |
|----------|--|
| <b>1</b> | EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are trapped to EL3. |
| <b>0</b> | EL2, EL1, and EL0 System register accesses to Performance Monitors registers are not trapped to EL3. |

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-80 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR\\_EL3](#).

**Table D1-80 Register accesses trapped to EL3 when [MDCR\\_EL3.TPM](#) is 1**

Traps from	Registers	Syndrome reporting in <a href="#">ESR_EL3</a>
AArch64 state	<a href="#">PMCR_EL0</a> , <a href="#">PMCNTENSET_EL0</a> , <a href="#">PMCNTENCLR_EL0</a> , <a href="#">PMOVSCLR_EL0</a> , <a href="#">PMSWINC_EL0</a> , <a href="#">PMSELR_EL0</a> , <a href="#">PMCEID0_EL0</a> , <a href="#">PMCEID1_EL0</a> , <a href="#">PMCCNTR_EL0</a> , <a href="#">PMXEVTYPER_EL0</a> , <a href="#">PMXVCNTR_EL0</a> , <a href="#">PMUSERENR_EL0</a> , <a href="#">PMINTENSET_EL1</a> , <a href="#">PMINTENCLR_EL1</a> , <a href="#">PMOVSSET_EL0</a> , <a href="#">PMEVCNTR&lt;n&gt;_EL0</a> , <a href="#">PMEVTYPER&lt;n&gt;_EL0</a> , <a href="#">PMCCFILTR_EL0</a> .	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
AArch32 state	<a href="#">PMCR</a> , <a href="#">PMCNTENSET</a> , <a href="#">PMCNTENCLR</a> , <a href="#">PMOVS</a> , <a href="#">PMSWINC</a> , <a href="#">PMSELR</a> , <a href="#">PMCEID0</a> , <a href="#">PMCEID1</a> , <a href="#">PMCCNTR</a> , <a href="#">PMXEVTYPER</a> , <a href="#">PMXVCNTR</a> , <a href="#">PMUSERENR</a> , <a href="#">PMINTENSET</a> , <a href="#">PMINTENCLR</a> , <a href="#">PMOVSSET</a> , <a href="#">PMEVCNTR&lt;n&gt;</a> , <a href="#">PMEVTYPER&lt;n&gt;</a> , <a href="#">PMCCFILTR</a> .	For accesses using: <ul style="list-style-type: none"> <li>MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</li> <li>MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04</li> </ul>

## D1.16 System calls

A system call is generated by the execution of an SVC, HVC, or SMC instruction:

- By default, the execution of an SVC instruction generates a Supervisor Call, a synchronous exception that targets EL1. This provides a mechanism for software executing at EL0 to make a call to an operating system or other software executing at EL1.
- In an implementation that includes EL2, the execution of an HVC instruction generates a Hypervisor Call, a synchronous exception that targets EL2 by default.

The HVC instruction is UNDEFINED:

- At EL0.
- At EL1 in Secure state.

———— **Note** ————

Software executing at EL0 cannot directly generate a Hypervisor Call.

- In an implementation that includes EL3, by default the execution of an SMC instruction generates a Secure Monitor Call, a synchronous exception that targets EL3.

The SMC instruction is UNDEFINED at EL0, meaning software executing at EL0 cannot directly generate a Secure Monitor Call.

The default behavior applies when the instruction is not UNDEFINED and both of the following are true:

- The instruction is executed at an Exception level that is the same as or lower than the target Exception level.
- The instruction is not trapped to a different Exception level.

If an SVC or HVC instruction is executed at an Exception level that is higher than the target Exception then it generates a synchronous exception that is taken to the current Exception level.

EL2 and EL3 can disable Hypervisor Call exceptions, see:

- [Disabling Non-secure state execution of HVC instructions on page D1-1854.](#)
- [Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions on page D1-1872.](#)

EL2 can trap use of the SMC instruction, see [Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1858.](#)

EL3 can disable Secure Monitor Call exceptions, see [Disabling EL3, EL2, and EL1 execution of SMC instructions on page D1-1873.](#)

### D1.16.1 Pseudocode description of system calls

The `AArch64.CallSupervisor()` pseudocode function performs an SVC call in AArch64 state.

The `AArch64.CallHypervisor()` pseudocode function performs an HVC call in AArch64 state.

The `AArch64.CallSecureMonitor()` pseudocode function performs an SMC call in AArch64 state.

The `AArch64.CallSupervisor()`, `AArch64.CallHypervisor()`, and `AArch64.CallSecureMonitor()` functions are described in [Chapter J1 ARMv8 Pseudocode](#).

## D1.17 Mechanisms for entering a low-power state

The ARM architecture provides mechanisms that software can use to indicate that the PE can enter a low-power state, if it supports that state. The following sections describe those mechanisms:

- [Wait for Event mechanism and Send event.](#)
- [Wait For Interrupt on page D1-1882.](#)

### D1.17.1 Wait for Event mechanism and Send event

A PE can use the *Wait for Event* (WFE) mechanism to enter a low-power state, depending on the value of the Event Register for that PE. To enter the low-power state, the PE executes a Wait For Event instruction, WFE, and if the Event Register is clear, the PE can enter the low-power state.

If the PE does enter the low-power state, it remains in that low-power state until it receives a *WFE wake-up event*.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFE instruction must not cause a loss of memory coherency.

WFE mechanism behavior depends on the interaction of all of the following, that are described in the subsections that follow:

- The Event Register for the PE. See subsection [The Event Register on page D1-1880](#).
- The Wait For Event instruction, WFE. See subsection [The Wait For Event instruction on page D1-1880](#).
- *WFE wake-up events*. See subsection [WFE wake-up events in AArch64 state on page D1-1881](#)
- The Send Event instructions, SEV and SEVL that can cause WFE wake-up events. See subsection [The Send Event instructions on page D1-1881](#).

#### ———— Note ————

Because the Wait for Event mechanism is associated with suspending execution on a PE for the purpose of power saving, ARM recommends that the Event Register is set only infrequently. However, software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

[Example D1-2](#) describes how a spinlock implementation might use the WFE mechanism to save energy.

#### Example D1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device, it might need to add data received from the device to a queue. If another PE is removing data from the same queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the second PE has released the lock. The first PE cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in [Synchronization and semaphores on page B2-121](#).
- If the PE obtains the lock it performs its memory operation and then releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. When the lock becomes available, the PE again attempts to obtain it.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multiprocessor system the execution of spin-locks by multiple waiting PEs can degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock:

- A PE that fails to obtain a lock executes a WFE instruction to request entry to a low-power state, at the time when the Exclusives monitor is set holding the address of the location holding the lock.
- When a PE releases a lock, the write to the lock location causes the Exclusives monitor of any PE monitoring the lock location to be cleared. This clearing of the Exclusives monitors generates a WFE wake-up event for each of those PEs. Then, these PEs can attempt to obtain the lock again.

For large systems, more advanced locking systems, such as ticket locks, can avoid unfairness caused by having multiple PEs simultaneously reading the lock. In such systems, the WFE mechanism can be used in a similar way to monitor the next ticket value.

---

## The Event Register

The Event Register is a single bit register for each PE. When set, an Event Register indicates that an event has occurred since the register was last cleared, that might require some action by the PE. Therefore, when the Event Register is set, the PE must not suspend operation on executing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by any of the following:

- A Send Event instruction, SEV, executed by any PE in the system.
- A Send Event Local instruction, SEVL, executed by the PE.
- An exception return.
- The clearing of the global monitor for the PE.
- An event from a Generic Timer event stream, see [Event streams on page D6-2186](#).
- An event sent by some IMPLEMENTATION DEFINED mechanism.

The Event Register is cleared only by a Wait For Event instruction.

---

### **Note**

Software cannot read or write the value of the Event Register directly.

---

## The Wait For Event instruction

The action of the Wait For Event instruction, WFE, depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately.
- If the Event Register is clear the PE can suspend execution and enter a low-power state. It remains in that state until the PE detects a WFE wake-up event, or earlier if the implementation chooses, or until a reset. When the PE detects a WFE wake-up event, or earlier if chosen, the WFE instruction completes. If the wake-up event sets the Event Register, it is IMPLEMENTATION DEFINED whether on restarting execution, the Event Register is cleared.

The WFE instruction is available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- [Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1845](#).
- [Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1861](#).
- [Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1871](#).

---

**Note**

---

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake-ups.

---

## WFE wake-up events in AArch64 state

The following are *WFE wake-up events*:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by [EDSCR.INTdis](#) and:
  - Is marked as **A** in the tables in *Asynchronous exception masking* on page D1-1836, regardless of the value of the corresponding [PSTATE.{A, I, F}](#) mask bit.
  - Is marked as **B** in the tables in *Asynchronous exception masking* on page D1-1836, if the value of the corresponding [PSTATE.{A, I, F}](#) mask bit is 0.
- In Non-secure EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by [EDSCR.INTdis](#) and is marked as **B** in Table D1-19 on page D1-1840 in *Virtual interrupts* on page D1-1839, if the value of the corresponding [PSTATE.{A, I, F}](#) mask bit is 0.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed* see *Halting allowed and halting prohibited* on page H2-5435.  
See also *External Debug Request debug event* on page H3-5490.
- An event sent by the timer event stream for the PE. See *Event streams* on page D6-2186.
- An event caused by the clearing of the global monitor for the PE.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

Not all of these wake-up events set the Event Register.

---

**Note**

---

The disabling of interrupts, and WFE wake-up events, by [EDSCR.INTdis](#) is possible only when external debug is enabled.

---

## The Send Event instructions

The Send Event instructions are:

**SEV, Send Event** This causes an event to be signaled to all PEs in the multiprocessor system.

**SEVL, Send Event Local**

This must set the local Event Register.

---

**Note**

---

It might signal an event to other PEs by some IMPLEMENTATION DEFINED mechanism, but is not required to do so.

---

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before any SEV instruction.

---

**Note**

---

A DSB instruction ensures that no instructions, including any SEV instructions, that appear in program order after the DSB instruction, can execute until the DSB instruction has completed. See [Data Synchronization Barrier \(DSB\) on page B2-93](#).

---

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

The receipt of a signaled SEV or SEVL event by a PE sets the Event Register on that PE.

The SEV and SEVL instructions are available at all Exception levels.

### Pseudocode description of the Wait For Event mechanism

This section identifies pseudocode functions that describe the behavior of the Wait For Event mechanism.

The [ClearEventRegister\(\)](#) pseudocode function clears the Event Register of the current PE.

The [IsEventRegisterSet\(\)](#) pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The [WaitForEvent\(\)](#) pseudocode function optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes [ClearEventRegister\(\)](#) to be called.

The [SendEvent\(\)](#) pseudocode function sets the Event Register of every PE in the multiprocessor system.

The [SendEventLocal\(\)](#) pseudocode function sets the event register for the local PE.

## D1.17.2 Wait For Interrupt

Software can use the *Wait for Interrupt (WFI)* instruction to cause the PE to enter a low-power state. The PE then remains in that low-power state until it receives a *WFI wake-up event*, or until some other IMPLEMENTATION DEFINED reason causes it to leave the low-power state. The architecture permits a PE to leave the low-power state for any reason, but requires that it must leave the low-power state on receipt of any architected WFI wake-up event.

---

**Note**

---

Because the architecture permits a PE to leave the low-power state for any reason, it is permissible for a PE to treat WFI as a NOP, but this is not recommended for lowest power operation.

---

When the PE leaves a low-power state that was entered as a result of a WFI instruction, that WFI instruction completes.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFI instruction must not cause a loss of memory coherency.

Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- [Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1845](#).
- [Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1861](#).
- [Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1871](#).

### WFI wake-up events

The following are *WFI wake-up events*:

- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as **A** as **B** in the tables in [Asynchronous exception masking on page D1-1836](#), regardless of the value of the corresponding **PSTATE**. {A, I, F} mask bit.

- In Non-secure EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as **B** in [Table D1-19 on page D1-1840](#) in *Virtual interrupts on page D1-1839*, regardless of the value of the corresponding `PSTATE.{A, I, F}` mask bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed* see *Halting allowed and halting prohibited on page H2-5435*.  
See also *External Debug Request debug event on page H3-5490*.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

---

**Note**

- WFI wake-up events are never disabled by `EDSCR.INTdis`, and are never masked by the `PSTATE.{A, I, F}` mask bits. If wake-up is invoked by an interrupt that is disabled or masked the interrupt is not taken.
- Because debug events are WFI wake-up events, ARM recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.
- Some implementations of the WFI mechanism drain down any pending memory activity before suspending execution. This increases power saving, by increasing the area over which clocks can be stopped. The architecture does not require this operation, therefore software must not rely on the WFI mechanism operating in this way.

---

## Using WFI to indicate an idle state on bus interfaces

Software can use the WFI mechanism to force quiescence on a PE, and, combined with preventing any possible WFI wakeup events, this can be used to complete an entry into a powerdown state.

Because mechanisms for entering powerdown states are inherently IMPLEMENTATION DEFINED, whether an implementation uses the WFI mechanism is IMPLEMENTATION DEFINED. If it does, the WFI instruction forces the suspension of execution, and of all associated bus activity.

The control logic that does this also tracks the activity on the bus interfaces of the PE, so that when the PE has completed all current operations and any associated bus activity has completed, it can signal to an external power controller that there is no ongoing bus activity.

However, the PE must continue to process memory-mapped and external debug interface accesses to debug registers when in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the OS Double Lock control, `OSDLR_EL1.DLK`, is 1, the PE must not signal this idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see *Debug behavior when the OS Double Lock is locked on page H6-5543*.

---

**Note**

In a PE that implements separate core and debug power domains, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see *Power domains and debug on page H6-5535*.

---

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

## Pseudocode description of Wait For Interrupt

The `WaitForInterrupt()` pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.

## D1.18 Self-hosted debug

The ARMv8-A architecture supports both of the following:

### Self-hosted debug

The PE itself hosts a debugger. The debugger programs the PE to generate *debug exceptions*. Debug exceptions are accommodated in the ARMv8-A Exception model.

### External debug

The PE is controlled by an external debugger. The debugger programs the PE to generate *Debug events*, that cause the PE to enter *Debug state*. In Debug state, the PE is halted.

This section describes self-hosted debug. It includes:

- [Debug exceptions](#).
- [The PSTATE debug mask bit, D](#).

For external debug, see part E.

### D1.18.1 Debug exceptions

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them.

For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

The possible debug exceptions are:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

[Chapter D2 AArch64 Self-hosted Debug](#) describes these in detail for AArch64.

For the PE to generate a debug exception requires that:

- The debug exception is enabled. [The debug exception enable controls on page D2-1910](#) gives the controls for the different debug exceptions.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level and Security state on page D2-1913](#).

Debug exceptions are synchronous exceptions, and are accommodated in the ARMv8 Exception model.

#### ———— **Note** ————

Breakpoints and Watchpoints can cause entry to Debug state instead of causing debug exceptions. See [Chapter H1 About External Debug](#).

### D1.18.2 The PSTATE debug mask bit, D

As with all other exceptions, when a debug exception is taken, software must take care to avoid generating another instance of an exception within the exception handler, to avoid recursive entry into the exception handler and loss of return state.

To help avoid this, the ARMv8 architecture provides a debug exception mask bit, [PSTATE.D](#), that can mask Watchpoint, Breakpoint, and Software Step exceptions when the target Exception level is the current Exception level.

**PSTATE.D** is set to 1 on taking an exception. This means that while handling an exception in AArch64 state, Watchpoint, Breakpoint, and Software Step exceptions are masked. This prevents recursive entry at the Exception level that debug exceptions are targeted to.

When execution is in AArch64 state, debug exceptions are also masked implicitly when the target Exception level is lower than the current Exception level.

When the target Exception level is higher than the current Exception level, debug exceptions cannot be masked by **PSTATE.D**.

Because debug exceptions are synchronous, the architecture requires that debug exceptions are not generated when **PSTATE.D** is 1. By preventing debug exception generation, debug exceptions cannot be taken at a subsequent time when the Process state D mask bit is cleared to 0.

---

**Note**

---

This differs from the behavior for interrupts, where the **PSTATE**.{A, I, F} mask has the effect of preventing the interrupt from being taken, but instead the interrupt remains pending.

---

## D1.19 The Performance Monitors Extension

The System registers provide access to a Performance Monitors Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE. The PMU provides:

- A 64-bit cycle counter.
- An IMPLEMENTATION DEFINED number of 32-bit event counters. Each event counter can be configured to count occurrences of a specified event. The events that can be counted are:
  - Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
  - Implementation-specific events. The PMU specification reserves event numbers for implementation-specific events. See [Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events](#).

For more information, see [Chapter D5 The Performance Monitors Extension](#).

## D1.20 Interprocessing

*Interprocessing* is the term used to describe moving between the AArch64 and AArch32 Execution states.

The Execution state can change only on a change of Exception level. This means that the Execution state can change only on taking an exception to a higher Exception level, or returning from an exception to a lower Exception level.

On taking an exception to a higher Exception level, the Execution state either:

- Remains unchanged.
- Changes from AArch32 state to AArch64 state.

On returning from an exception to a lower Exception level, the Execution state either:

- Remains unchanged.
- Changes from AArch64 state to AArch32 state.

---

### Note

If, on taking or returning from an exception, the Exception level remains the same, the Execution state cannot change.

---

For the description of:

- Exception entry to an Exception level using AArch64, see [Exception entry on page D1-1799](#).
- Exception return from an Exception level using AArch64 state, see [Exception return on page D1-1815](#).
- Exception return to AArch32 state, see [Exception return to an Exception level using AArch32 on page G1-4360](#).

---

### Note

The description in [Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340](#) is outside the scope of interprocessing, because such exceptions must have been taken from an Exception level that is using AArch32, and therefore there is no change of Execution state.

---

The following sections describe the behavior associated with interprocessing.

- [Register mappings between AArch32 state and AArch64 state](#).
- [State of the general-purpose registers on taking an exception to AArch64 state on page D1-1896](#).
- [SPSR, ELR, and AArch64 SP relationships on changing Execution state on page D1-1897](#).

### D1.20.1 Register mappings between AArch32 state and AArch64 state

This section defines the architectural mappings between AArch32 state registers and AArch64 state registers.

The mappings describe:

- For exceptions taken from AArch32 state to AArch64 state, where the AArch32 register content is found.
- For exception returns from AArch64 state to AArch32 state, how the AArch32 register content is derived.

The general model is:

- The AArch32 register contents are situated in the bottom 32 bits of the AArch64 registers.
- In AArch32 state, the upper 32 bits of AArch64 registers are inaccessible and are ignored.

---

### Note

System software that executes in AArch64 state, such as an OS or Hypervisor, can use these mappings for context save and restore, or to interpret and modify the AArch32 registers of an application or virtual machine.

---

For more information see the following subsections:

- [Mapping of the general-purpose registers between the Execution states.](#)
- [Mapping of the SIMD and floating-point registers between the Execution states on page D1-1889.](#)
- [Mapping of the System registers between the Execution states on page D1-1890.](#)

## Mapping of the general-purpose registers between the Execution states

[Table D1-81](#) shows how each of the AArch32 general-purpose registers, R0-R12, SP, and LR, including the banked copies of these registers, maps to an AArch64 general-purpose register. A register in the *AArch64 register* column of the table provides the AArch64 view of the corresponding register in the *AArch32 register* column.

### ———— Note —————

For some exceptions, the exception syndrome given in the [ESR\\_ELx](#) identifies one or more register numbers from the issued instruction that generated the exception. Where the exception is taken from an Exception level using AArch32 these register numbers give the AArch64 view of the register. For example, if an exception is taken from AArch32 Abort mode, and the faulting instruction specified R14, the [ESR\\_ELx.ISS](#) field would report this using the EC value `0b10100`, because register X20 provides the AArch64 view of LR\_abt. which is the copy of R14 used in Abort mode.

**Table D1-81 General-purpose register mapping between AArch32 state and AArch64 state**

**Note**

For a description of the banking of AArch32 general-purpose registers R8-R12, SP, and LR, see [AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-4327](#).

**Mapping of the SIMD and floating-point registers between the Execution states**

[Table D1-82](#) shows the mapping between the AArch64 V registers and the AArch32 Q registers.

**Table D1-82 SIMD and floating-point register mapping between AArch64 state and AArch32 state**

AArch64 register	AArch32 register
V0	Q0
V1	Q1
V2	Q2
.	.
.	.
.	.
V15	Q15

The AArch64 registers V16-V31 are not accessible from AArch32 state.

The mapping between the V, D, and S registers in AArch64 state is not the same as the mapping between the Q, D, and S registers in AArch32 state:

- In AArch64 state, there are:
  - 32 128-bit V registers, V0-V31.
  - 32 64-bit D registers, D0-D31.
  - 32 32-bit S registers, S0-S31.

A smaller register occupies the least-significant bytes of the corresponding larger register. For example, S5 is the least-significant word of D5 and V5. [Figure D1-3](#) shows this mapping.

**Figure D1-3 AArch64 state SIMD and floating-point register mappings**

- In AArch32 state, there are:
  - 16 128-bit Q registers, Q0-Q15.
  - 32 64-bit D registers, D0-D31.
  - 32 32-bit S registers, S0-S31.

Smaller registers are packed into larger registers. [Figure D1-4](#) shows this mapping.

**Figure D1-4 AArch32 state SIMD and floating-point register mappings**

In AArch32 state:

- There are no S registers that correspond to Q8-Q15.
- D16-D31 pack into Q8-Q15. For example, D16 and D17 pack into Q8.

#### **Note**

A consequence of this mapping is that if software executing in AArch64 state interprets D or S registers from AArch32 state, it must unpack the D or S registers from the V registers before it uses them.

## **Mapping of the System registers between the Execution states**

ARMv8 architecturally defines the relationship between the AArch64 System registers and the AArch32 System registers, to allow supervisory code such as a hypervisor, that is executing in AArch64 state, to save, restore, and interpret the System registers belonging to a lower Exception level that is using AArch32.

Any modifications made to AArch32 System registers affects only those parts of those AArch64 registers that are mapped to the AArch32 System registers. Bits[63:32] of AArch64 registers, where they are not mapped to AArch32 registers, are unchanged by AArch32 state execution.

#### **Note**

This model is different to the model for the general-purpose registers described in [Mapping of the general-purpose registers between the Execution states on page D1-1888](#). In this model, there are several cases where two AArch32 System registers are packed into a single AArch64 System register.

When EL3 is implemented and is using AArch32, some System registers are banked between the two Security states. When a register is banked in this way, there is an instance of the register in Secure state, and another instance of the register in Non-secure state. In [Table D1-83 on page D1-1891](#) these banked registers are identified by footnote<sup>a</sup>. This banking is not supported when EL3 is using AArch64 or if EL3 is not implemented. This means that when EL3 is implemented and is using AArch64, exactly the same registers are accessed in the following states:

- Secure EL1 with EL1 using AArch32.
- Non-secure EL1 with EL1 using AArch32.

This means that, architecturally, it is not possible to determine whether an AArch64 register is mapped onto the Secure instance of the corresponding AArch32 register, or onto the Non-secure instance of that register. When EL3 is using AArch64, the interrupt asserted by the AArch64 CNTP\_\* timer is the same interrupt as is asserted by the Non-secure AArch32 CNTP\_\* timer when EL3 is using AArch32.

———— **Note** ————

Although the architecture does not require this, because it is not architecturally visible, ARM expects that implementations will map many of the AArch64 registers for use by EL3 to the Secure instances of the banked AArch32 registers, and will map many of the AArch64 registers for use by EL1 to the Non-secure instances of the banked AArch32 registers. However, if EL2 and EL3 are implemented and both support use of AArch32, this is not possible for the following registers:

**IFAR** This is because when EL3 is using AArch32, **HIFAR** is an alias of the Secure **IFAR**.

**DFAR** This is because when EL3 is using AArch32, **HDFAR** is an alias of the Secure **DFAR**.

Table D1-83 shows the mappings between the writable AArch64 System registers and the AArch32 System registers.

**Table D1-83 Mapping of writable AArch64 System registers to the AArch32 System registers**

a. AArch32 registers that are banked if EL3 is using AArch32.

b. These registers have overlapping register content. One or more bits of one register appear in the other register.

There are a small number of AArch32 System registers that are not mapped to any AArch64 System registers. The AArch64 registers listed in [Table D1-84](#) can be used to access these from a higher Exception level that is using AArch64. The registers shown in the table are UNDEFINED if EL1 cannot use AArch32.

**Table D1-84 AArch64 registers for accessing registers that are only used in AArch32 state**

AArch32 register	AArch64 register for accessing the AArch32 register	Short description

## D1.20.2 State of the general-purpose registers on taking an exception to AArch64 state

When an exception is taken from AArch32 state to AArch64 state, the state of a general-purpose register depends on whether, immediately before the exception, the register was accessible from AArch32 state, as follows:

### If the general-purpose register was accessible from AArch32 state

The upper 32 bits either become zero, or hold the value that the same architectural register held before any AArch32 execution. The choice between these two options is IMPLEMENTATION DEFINED, and might vary dynamically within an implementation. Correspondingly, software must regard the value as being a CONSTRAINED UNPREDICTABLE choice between these two values.

This behavior applies regardless of whether any execution occurred at the Exception level that was using AArch32. That is, this behavior applies even if AArch32 state was entered by an exception return from AArch64 state, and another exception was immediately taken to AArch64 state without any instruction execution in AArch32 state.

Which general-purpose registers have their upper 32 bits affected in this way depends on both:

- The AArch64 state target Exception level.
- The values of both:
  - [SCR\\_EL3.RW](#).
  - [HCR\\_EL2.RW](#) or [HCR.RW](#), where [HCR.RW](#) is a notional bit that is RES0.

[Table D1-86](#) shows which general-purpose registers can have their upper 32 bits set to zero.

**Table D1-86 General-purpose registers that can have their upper 32 bits set to zero on taking an exception to AArch64 state from AArch32 state**

		Registers when the target Exception level is:		
<a href="#">SCR_EL3.RW</a>	<a href="#">HCR_EL2.RW</a> or <a href="#">HCR.RW</a> <sup>a</sup>	EL3	EL2	EL1
0	0	X0-X30	_b	_b
0	1	_c	_c	_c
1	0	X0-X14, X16-X30	X0-X14, X16-X30	_b
1	1	X0-X14	X0-X14	X0-X14

- a. [HCR.RW](#) is a notional bit that is RES0.  
 b. The RW bit values are not valid for the targeted Exception level.  
 c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

### Note

If EL2 is not implemented, or the [SCR\\_EL3.NS](#) or [SCR.NS](#) bit prevents its use, then as described in *The effects of supporting fewer than four Exception levels on page D1-1901*, the behavior is consistent with [HCR\\_EL2.RW](#) taking the value of [SCR\\_EL3.RW](#).

### If the general-purpose register was not accessible from AArch32 state

The general rule is that the register retains the state it had before any AArch32 execution.

There is one exception to this rule, that is when taking an exception to EL3 using AArch64 when either EL2 is not implemented or EL1 is in Secure state. In these cases, the X15 register must be treated as if it is accessible when the value of [SCR\\_EL3.RW](#) is 0, and therefore the upper bits of X15 might either be set to zero or retain their previous value.

Which general-purpose registers retain their state depends on both:

- The AArch64 state target Exception level.
- The values of both:
  - [SCR\\_EL3.RW](#).

— [HCR\\_EL2.RW](#) or [HCR.RW](#), where [HCR.RW](#) is a notional bit that is RES0.

[Table D1-87](#) shows which general-purpose registers can retain their state.

**Table D1-87 General-purpose registers that can retain their state on taking an exception to AArch64 from AArch32**

<a href="#">SCR_EL3.RW</a>	<a href="#">HCR_EL2.RW</a> or <a href="#">HCR.RW</a> <sup>a</sup>	Registers when the target Exception level is:		
		EL3	EL2	EL1
0	0	None	_b	_b
0	1	_c	_c	_c
1	0	X15	X15	_b
1	1	X15-X30	X15-X30	X15-X30

- a. [HCR.RW](#) is a notional bit that is RES0.  
b. The RW bit values are not valid for the targeted Exception level.  
c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

**Note**

If EL2 is not implemented, or the [SCR\\_EL3.NS](#) bit prevents its use, then as described in *The effects of supporting fewer than four Exception levels on page D1-1901*, the behavior is consistent with [HCR\\_EL2.RW](#) taking the value of [SCR\\_EL3.RW](#).

### D1.20.3 SPSR, ELR, and AArch64 SP relationships on changing Execution state

[Table D1-88](#) shows the SPSR and ELR registers that are architecturally mapped between AArch32 state and AArch64 state.

**Table D1-88 SPSR and ELR mappings between AArch32 state and AArch64 state**

AArch32 register	AArch64 register
<a href="#">SPSR_svc</a>	<a href="#">SPSR_EL1</a>
<a href="#">SPSR_hyp</a>	<a href="#">SPSR_EL2</a>
<a href="#">ELR_hyp</a>	<a href="#">ELR_EL2</a>

On exception entry to EL3 using AArch64 state from an Exception level using AArch32 state, when EL2 has been using AArch32 state, the upper 32-bits of [ELR\\_EL2](#) are either set to zero or they retain the value before the AArch32 state execution. The implementation determines the choice between these two options, and the choice might vary dynamically within an implementation. Therefore, software must regard the upper 32-bits as being UNKNOWN.

On exception entry to an Exception level using AArch64 state from an Exception level using AArch32 state, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during execution in AArch32 state at that Exception level, retain the state that they had before the execution in AArch32 state.

The following AArch32 registers are used only during execution in AArch32 state. However, they retain their state when there is execution at EL1 with EL1 using AArch64 state:

- [SPSR\\_abt](#).
- [SPSR\\_und](#).
- [SPSR\\_irq](#).

- [SPSR\\_fiq.](#)

---

**Note**

---

- These registers are accessible during execution in AArch64 state at Exception levels higher than EL1, for context switching.
- If EL1 does not support execution in AArch32 state then these registers are RES0.

---

On exception entry to an Exception level using AArch64 from an Exception level using AArch32, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during AArch32 execution at that Exception level retain the state that they had before AArch32 execution. This applies to the following registers:

- [SP\\_EL0.](#)
- [SP\\_EL1.](#)
- [SP\\_EL2.](#)
- [ELR\\_EL1.](#)

## D1.21 The effect of implementation choices on the programmers' model

Three of the implementation choices in ARMv8 are:

- The number of Exception levels implemented.
- Which Exception levels support AArch32 and which Exception levels support AArch64.
- Whether SIMD and floating-point support is implemented.

The following subsections give more information about how these choices affect the programmers' model:

- [Implication of Exception levels implemented.](#)
- [Support for Exception levels and Execution states on page D1-1900.](#)
- [Implementations not including Advanced SIMD and floating-point instructions on page D1-1901.](#)
- [The effects of supporting fewer than four Exception levels on page D1-1901.](#)

### D1.21.1 Implication of Exception levels implemented

All implementations must include EL0 and EL1.

EL2 and EL3 are optional. The architecture permits all combinations of EL2 and EL3.

See also [Implementations not including Advanced SIMD and floating-point instructions on page D1-1901](#) and [The effects of supporting fewer than four Exception levels on page D1-1901](#).

For an implementation that includes all of the Exception levels [Figure D1-5](#) shows the implemented Exception levels and the possible Execution states at lower Exception levels when EL3 is using AArch64. [Figure D1-5](#) applies regardless of whether EL3 also supports use of AArch32.

† AArch64 permitted only if EL1 is using AArch64

‡ AArch64 permitted only if EL2 is using AArch64

**Figure D1-5 ARMv8-A security model when EL3 is using AArch64**

The possible combinations of Exception levels are as follows:

- EL0, EL1, and EL2. The implementation supports only Non-secure state.

- EL0, EL1, and EL3. The implementation does not support Virtualization. The Exception levels and Execution states depend on whether EL3 is using AArch64 state or AArch32 state, as follows:
  - If EL3 is using AArch64, the Exception levels and Execution states are as shown in [Figure D1-5 on page D1-1899](#) with EL2 removed and no Non-secure state virtualization of EL1 and EL0.
  - If EL3 is using AArch32, the Exception levels and Execution states are as shown in [Figure G1-1 on page G1-4316](#) with EL2 removed and no Non-secure state virtualization of EL1 and EL0.
- EL0 and EL1 only. The implementation supports only a single Security state. This might be either Secure state or Non-secure state, see [Behavior when only EL1 and EL0 are implemented on page D1-1902](#).
- EL0, EL1, EL2, and EL3, as described in this section.

For more information, see [The effects of supporting fewer than four Exception levels on page D1-1901](#).

## D1.21.2 Support for Exception levels and Execution states

Subject to the interprocessing rules defined in [Interprocessing on page D1-1887](#), an implementation of the ARM architecture could support:

- AArch64 state only.
- AArch64 and AArch32 states.
- AArch32 state only.

This means the ARMv8-A architecture can, potentially, support implementations with very large number of combinations of Execution state and Exception level. ARM intends to license only a subset of the possible combinations. [Table D1-89](#) shows the combinations of Exception levels and Execution states that are currently licensed.

**Table D1-89 Supported combinations of Exception levels and Execution state**

Number of Exception levels	Supported Security states	Exception levels, AArch64 state				Exception levels, AArch32 state			
		EL3	EL2	EL1	EL0	EL3	EL2	EL1	EL0
Four	Both	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
		Yes	Yes	Yes	Yes	No	No	Yes	Yes
		Yes	Yes	Yes	Yes	No	No	No	Yes
		Yes	Yes	Yes	Yes	No	No	No	No
		No	No	No	No	Yes	Yes	Yes	Yes
Three	Both	Yes	No	Yes	Yes	No	No	Yes	Yes
		Yes	No	Yes	Yes	No	No	No	Yes
		Yes	No	Yes	Yes	No	No	No	No
		No	No	No	No	Yes	No	Yes	Yes
	Non-secure only	No	Yes	Yes	Yes	No	No	Yes	Yes
		No	Yes	Yes	Yes	No	No	No	No
Two	Either	No	No	Yes	Yes	No	No	No	Yes
		No	No	Yes	Yes	No	No	No	No
		No	No	No	No	No	No	Yes	Yes

### D1.21.3 Implementations not including Advanced SIMD and floating-point instructions

In general, ARMv8-A requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementations targeting specialized markets that do not require support for floating-point or use of Advanced SIMD, ARM might produce or license an ARMv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation:

#### In AArch64 state

- The [CPACR\\_EL1.FPEN](#) field is RES0.
- The [CPTR\\_EL2.TFP](#) bit is RES1.
- The [CPTR\\_EL3.TFP](#) bit is RES1.
- Each of the [ID\\_AA64PFR0\\_EL1](#).{AdvSIMD, FP} fields is 0b1111.
- The [FPEXC32\\_EL2](#), [FPCR](#), and [FPSR](#) registers are not implemented, and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
  - All Advanced SIMD and floating-point instructions are UNDEFINED.
  - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.
- If at least one Exception level supports execution in AArch32 state, the [MVFR0\\_EL1](#), [MVFR1\\_EL1](#) and [MVFR2\\_EL1](#) registers are RAZ. When no Exception level supports execution in AArch32 state these registers are UNKNOWN.

#### In AArch32 state

See [AArch32 implications of not including support for Advanced SIMD and floating-point on page G1-4412](#).

### D1.21.4 The effects of supporting fewer than four Exception levels

[The effect of implementation choices on the programmers' model on page D1-1899](#) defines the permitted combinations of Exception levels in an ARMv8-A implementation.

In every implementation that supports the highest Exception level using either AArch64 state or AArch32 state, an IMPLEMENTATION DEFINED mechanism determines whether the highest implemented Exception level uses AArch64 state or AArch32 state from a Cold reset. Typically, this mechanism is a configuration input. When the highest level is configured to be AArch64 state, then after a Cold reset execution starts at the reset vector in that Exception level.

The unimplemented Exception levels have no effect on execution:

- No interrupts are routed to these Exception levels.
- No traps that target these Exception levels are active
- All systems calls to unimplemented Exception levels from lower Exception levels are treated as UNDEFINED.
- There is no support for address translation from these Exception levels.
- Any exception return that targets an unimplemented Exception level is treated as an illegal exception return as described in [Illegal return events from AArch64 state on page D1-1816](#).
- Every accessible register associated with an unimplemented Exception level is RES0 unless the register is associated with the Exception level only to provide the ability to transfer execution to a lower Exception level.

#### ———— Note ————

If, for example, EL3 is not implemented and EL2 is the highest implemented Exception level, then because none of the EL3 registers are accessible from EL2, the content of those registers is not architecturally visible.

The following subsections give more information about each of the permitted combinations of Exception levels that do not include all Exception levels.

## Behavior when EL2 is not implemented

If EL2 is not implemented and EL3 is implemented:

- If EL1 can use AArch32 then the following registers are not RES0:
    - [DACR32\\_EL2](#).
    - [IFSR32\\_EL2](#).
    - [FPEXC32\\_EL2](#).
    - [DBGVCR32\\_EL2](#).
  - The [VMPIDR\\_EL2](#) and [VPIDR\\_EL2](#) behave as follows:
    - Reads of [VMPIDR\\_EL2](#) return the value of [MPIDR\\_EL1](#), writes to [VMPIDR\\_EL2](#) are ignored.
    - Reads of [VPIDR\\_EL2](#) return the value of [MIDR\\_EL1](#), writes to [VPIDR\\_EL2](#) are ignored.
  - Behavior is consistent with the [HCR\\_EL2.RW](#) bit taking the value of the [SCR\\_EL3.RW](#) bit for all purposes other than reading the [HCR\\_EL2](#).
  - Virtual interrupts are disabled.
  - The following address translation and TLB invalidation instructions are UNDEFINED:
    - [AT S1E2R](#) and [AT S1E2W](#).
    - [TLBI VAE2](#), [TLBI VALE2](#), [TLBI VAE2IS](#), [TLBI VALE2IS](#), [TLBI ALLE2](#), [TLBI ALLE2IS](#).
- Note**
- No other TLB or address translation instructions become UNDEFINED with this combination of Exception levels.
- The [SCR\\_EL3.HCE](#) bit is RES0.

If EL2 is not implemented, regardless of whether EL3 is implemented:

- The [CNTHCTL\\_EL2](#)[1:0] bits are treated as if they have the value 0b11 for all purposes other than reading the [CNTHCTL\\_EL2](#) register.
- The [MDCR\\_EL2.HPMN](#) bit taking the value of the [PMCR\\_EL0.N](#) bit for all purposes other than reading the value of [MDCR\\_EL2.HPMN](#).

## Behavior when EL3 is not implemented and EL2 is implemented

If EL3 is not implemented and EL2 is implemented, then:

- All memory transactions can only access a single physical memory address space.
- The PE behaves as if the value of the [SCR\\_EL3.NS](#) bit is 1, even though the [SCR\\_EL3](#) is not accessible.

This means that if the PE is part of a system that supports two Security states, it behaves as if it is in Non-secure state, and can only access Non-secure memory.

## Behavior when only EL1 and EL0 are implemented

If EL3 and EL2 are not implemented, it is IMPLEMENTATION DEFINED whether the PE behaves as if the value of the [SCR\\_EL3.NS](#) bit is 1 or the PE behaves as if the value of the [SCR\\_EL3.NS](#) bit is 0.

This means that if the PE is part of a system that supports two Security states:

- If it behaves as if the value of the [SCR\\_EL3.NS](#) bit is 1, it can only access Non-secure memory.
- If it behaves as if the value of the [SCR\\_EL3.NS](#) bit is 0, it can access both Secure memory and Non-secure memory.

If the PE behaves as if the value of the [SCR\\_EL3.NS](#) bit is 0, then:

- The [MDCR\\_EL3](#).{EPMAD, EDAD, SPME} bits behave as if they have the value 1.

- The [MDCR\\_EL3](#).SPD32 field behaves as if it has the value 0b11.

---

**Note**

- The behavior described in this subsection still applies if EL1 is configured to use AArch32.
  - The implementation can provide a configuration input that determines, from reset, whether the it behaves as if the value of the [SCR\\_EL3](#).NS bit is 1, or as if the value of the [SCR\\_EL3](#).NS bit is 0.
-

# Chapter D2

## AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch64 self-hosted debug exception model. It is organized as follows:

### Introductory information

- [About self-hosted debug](#) on page D2-1906.
- [The debug exception enable controls](#) on page D2-1910.

### The debug Exception model

- [Routing debug exceptions](#) on page D2-1911.
- [Enabling debug exceptions from the current Exception level and Security state](#) on page D2-1913.
- [The effect of powerdown on debug exceptions](#) on page D2-1915.
- [Summary of the routing and enabling of debug exceptions](#) on page D2-1916.
- [Pseudocode description of debug exceptions](#) on page D2-1918.

### The debug exceptions

- [Breakpoint Instruction exceptions](#) on page D2-1919.
- [Breakpoint exceptions](#) on page D2-1921.
- [Watchpoint exceptions](#) on page D2-1940.
- [Vector Catch exceptions](#) on page D2-1955.
- [Software Step exceptions](#) on page D2-1956.

### Synchronization requirements

The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a [Context synchronization event](#) guarantees the effects of the changes:

- [Synchronization and debug exceptions](#) on page D2-1970.

## D2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of *debug exceptions*, that are taken using the exception model described in [Chapter D1 The AArch64 System Level Programmers' Model](#). This section introduces some terms that are used in describing self-hosted debug, and then introduces the debug exceptions. See:

- [Definition of a debugger in the context of self-hosted debug](#).
- [Context ID and Process ID](#).
- [About debug exceptions](#).

### D2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, *debugger* means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

### D2.1.2 Context ID and Process ID

A [CONTEXTIDR\\_ELx](#) identifies the current *Context ID*, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

In AArch64 state, the [CONTEXTIDR\\_ELx](#) has a single field, PROCID, that is defined as the *Process Identifier* (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical.

### D2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger enables one or more debug exceptions. The debug exceptions that can be generated in stage 1 of an AArch64 translation regime are:

- [Breakpoint Instruction exceptions on page D2-1907](#).
- [Breakpoint exceptions on page D2-1907](#), generated by hardware breakpoints.
- [Watchpoint exceptions on page D2-1907](#), generated by hardware watchpoints.
- [Software Step exceptions on page D2-1908](#).

In addition, debug exceptions generated in an AArch32 translation regime might be routed to EL2 using AArch64. See [Routing debug exceptions on page D2-1911](#). [Chapter G2](#) describes the debug exceptions that can be generated in an AArch32 translation regime.

*Vector Catch exceptions* are exceptions that cannot be generated in an AArch64 translation regime but can be generated in stage 1 of an AArch32 translation regime and routed to EL2 using AArch64. [Vector Catch exceptions on page D2-1955](#) describes the behavior for this case.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.  
See [Enabling debug exceptions from the current Exception level and Security state on page D2-1913](#).  
Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
2. A debugger has enabled that particular debug exception.  
All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the [MDSCR\\_EL1](#). See [The debug exception enable controls on page D2-1910](#).

### Note

If *halting is allowed* and `EDSCR.HDE` is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see [Halting allowed and halting prohibited on page H2-5435](#).

The following list summarizes each of the debug exceptions:

#### Breakpoint Instruction exceptions

*Breakpoint instructions* generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

##### PE behavior

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Exception level.
- The current Security state.

For more information, see [Breakpoint Instruction exceptions on page D2-1919](#).

#### Breakpoint exceptions

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The ARMv8-A architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch64 translation regime:

- Address.
  - Comparisons are made with the virtual address of each instruction in the program flow.
- Context:
  - Context ID Match. Matches with the Context ID held in the `CONTEXTIDR_EL1`.
  - `VMID` Match. Matches with the `VMID` value held in the `VTTBR_EL2`.
  - Context ID and `VMID` Match. Matches with both the Context ID and the `VMID` value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

##### PE behavior

If halting is allowed and `EDSCR.HDE` is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See [Chapter H2 Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see [Breakpoint exceptions on page D2-1921](#).

#### Watchpoint exceptions

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range 0x1000 - 0x101F.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

#### PE behavior

If halting is allowed and `EDSCR.HDE` is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See [Chapter H2 Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see [Watchpoint exceptions on page D2-1940](#).

#### Vector Catch exceptions

These are not generated in an AArch64 translation regime. They can only be generated in an AArch32 translation regime. See [Vector Catch exceptions on page D2-1955](#).

#### Software Step exceptions

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.

After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

#### PE behavior

Software step can only be used by a debugger executing in an Exception level that is using AArch64. However, the instruction stepped might be executed in either Execution state, and therefore Software Step exceptions can be taken from either Execution state.

If debug exceptions are enabled, Software Step exceptions can be generated.

If debug exceptions are disabled, software step is inactive.

For more information, see [Software Step exceptions on page D2-1956](#).

[Table D2-1](#) summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

**Table D2-1 PE behavior and pseudocode for each of the debug exceptions**

Debug exception	PE behavior if debug exceptions are:		Pseudocode
	Enabled	Disabled	
Breakpoint Instruction exceptions	Takes the exception	Takes the exception	<a href="#">Pseudocode description of Breakpoint Instruction exceptions on page D2-1920</a>
Breakpoint exceptions	Takes the exception <sup>a</sup>	Ignored	<a href="#">Pseudocode description of Breakpoint exceptions taken from AArch64 state on page D2-1939</a>

**Table D2-1 PE behavior and pseudocode for each of the debug exceptions (continued)**

Debug exception	PE behavior if debug exceptions are:		Pseudocode
	Enabled	Disabled	
Watchpoint exceptions	Takes the exception <sup>a</sup>	Ignored	<i>Pseudocode description of Watchpoint exceptions taken from AArch64 state on page D2-1953</i>
Vector Catch exceptions	Takes the exception	Ignored	<i>Pseudocode description of Vector Catch exceptions on page G2-4517</i>
Software Step exceptions	Takes the exception	Not applicable <sup>b</sup>	<i>Pseudocode description of Software Step exceptions on page D2-1969</i>

- a. If halting is allowed and [EDSCR.HDE](#) is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See [Chapter H2 Debug State](#).
- b. Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.

## D2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

### Breakpoint Instruction exceptions

None. Breakpoint Instruction exceptions are always enabled.

### Breakpoint exceptions

[MDSCR\\_EL1.MDE](#), plus an enable control for each breakpoint, [DBGBCR<n>\\_EL1.E](#).

### Watchpoint exceptions

[MDSCR\\_EL1.MDE](#), plus an enable control for each watchpoint, [DBGWCR<n>\\_EL1.E](#).

### Vector Catch exceptions

[MDSCR\\_EL1.MDE](#).

### Software Step exceptions

[MDSCR\\_EL1.SS](#).

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level and Security state on page D2-1913](#).

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

## D2.3 Routing debug exceptions

The routing of debug exceptions is as follows:

### Debug exceptions taken from Non-secure state when EL2 is implemented

The routing of debug exceptions taken from Non-secure state depends on the values of [MDCR\\_EL2.TDE](#) and [HCR\\_EL2.TGE](#):

**If the value of {[MDCR\\_EL2.TDE](#), [HCR\\_EL2.TGE](#)} is not {0, 0}**

Debug exceptions taken from Non-secure state are routed to EL2.

#### Otherwise

In Non-secure state, debug exceptions behave as follows:

- Debug exceptions taken from Non-secure EL1 and Non-secure EL0 are routed to Non-secure EL1.
- Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
- All other debug exceptions are disabled from EL2 using AArch64.

#### Note

If EL2 is not implemented, the *Effective value* of [HCR\\_EL2.TGE](#) is 0 and the *Effective value* of [MDCR\\_EL2.TDE](#) is 0. Throughout this section, references to the values of these fields are to the *Effective values* of the fields.

### When EL3 is implemented

Breakpoint Instruction exceptions taken from EL3 are routed to EL3.

All other debug exceptions are disabled from EL3 using AArch64.

**Otherwise** Debug exceptions are routed to EL1.

This means that, for all debug exceptions, the *Debug target Exception level*,  $EL_D$ , is either EL1 or EL2:

- $EL_D$  is EL2 if all of the following apply:
  - EL2 is implemented.
  - The *Effective value* of [SCR\\_EL3.NS](#) is 1.
  - The value of {[MDCR\\_EL2.TDE](#), [HCR\\_EL2.TGE](#)} is not {0, 0}.
- Otherwise  $EL_D$  is EL1.

[Table D2-2 on page D2-1912](#), [Table D2-3 on page D2-1912](#), and [Table D2-4 on page D2-1912](#) show the routing of debug exceptions. In these tables:

<b>TDE</b>	Means the logical OR of <a href="#">MDCR_EL2.TDE</a> and <a href="#">HCR_EL2.TGE</a> .
<b>NS</b>	Means the <i>Effective value</i> of <a href="#">SCR_EL3.NS</a> .
<b>(EL<sub>x</sub>)</b>	Means $EL_D$ is EL <sub>x</sub> . However: <ul style="list-style-type: none"> <li>• All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Exception level.</li> <li>• Breakpoint Instruction exceptions taken from this Exception level are routed to this Exception level.</li> </ul>
<b>EL<sub>x</sub></b>	Means $EL_D$ is EL <sub>x</sub> .

**Table D2-2 Routing when both EL3 and EL2 are implemented**

NS	TDE	EL <sub>D</sub> when executing in:			
		EL0	EL1	EL2	EL3
0	x	EL1	EL1	(EL1)	(EL1)
1	0	EL1	EL1	(EL1)	(EL1)
1	1	EL2	EL2	EL2	(EL2)

**Table D2-3 Routing when EL3 is implemented and EL2 is not implemented**

EL <sub>D</sub> when executing in:		
EL0	EL1	EL3
EL1	EL1	(EL1)

**Table D2-4 Routing when EL3 is not implemented and EL2 is implemented**

TDE	EL <sub>D</sub> when executing in:		
	EL0	EL1	EL2
0	EL1	EL1	(EL1)
1	EL2	EL2	EL2

### D2.3.1 Pseudocode description of routing debug exceptions

[DebugTarget\(\)](#) returns the current debug target Exception level.

[DebugTargetFrom\(\)](#) returns the debug target Exception level for the specified Security state.

These functions are described in [Chapter J1 ARMv8 Pseudocode](#).

## D2.4 Enabling debug exceptions from the current Exception level and Security state

A debug exception can only be taken if all of the following are true:

- The OS lock is unlocked.
- `DoubleLockStatus() == FALSE`.
- The debug exception is enabled from the current Exception level.
- The debug exception is enabled from the current Security state.

Table D2-5 shows when debug exceptions are enabled from the current Exception level. In the table, `ELD` is the Exception level that Table D2-2 on page D2-1912 defines.

**Table D2-5 Whether debug exceptions are enabled from the current Exception level**

Current Exception level	Breakpoint Instruction exceptions	All other debug exceptions
Any Exception level that is higher than <code>EL<sub>D</sub></code> <sup>a</sup>	Enabled	Disabled
<code>EL<sub>D</sub></code>	Enabled	Disabled if either of the following is true: <ul style="list-style-type: none"> <li>• The Local (kernel) Debug Enable bit, <code>MDSCR_EL1.KDE</code>, is 0.</li> <li>• The Debug exception mask bit, <code>PSTATE.D</code>, is 1.</li> </ul> Otherwise enabled. This means that a debugger must explicitly enable these debug exceptions from <code>EL<sub>D</sub></code> by setting <code>MDSCR_EL1.KDE</code> to 1 and <code>PSTATE.D</code> to 0.
Any Exception level that is lower than <code>EL<sub>D</sub></code>	Enabled	Enabled

a. This includes `EL3`. `EL3` is always higher than `ELD`.

### ———— Note ————

`PSTATE.D` is set to 1 at reset and on exception entry.

Table D2-6 shows when debug exceptions are enabled from the current Security state.

**Table D2-6 Whether debug exceptions are enabled from the current Security state**

Current Security state	Breakpoint Instruction exceptions	All other debug exceptions
Non-secure	Enabled	Enabled
Secure	Enabled	Disabled if <code>MDCR_EL3.SDD</code> is 1. See <i>Disabling debug exceptions from Secure state</i> on page D2-1914. Otherwise enabled.

## D2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can set the *Secure Debug Disable* bit, [MDCR\\_EL3.SDD](#), to 1 to disable all debug exceptions taken from AArch64 Secure state other than Breakpoint Instruction exceptions.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

---

### Note

- If the boot software executed when reset is deasserted sets [MDCR\\_EL3.SDD](#) to 1, software operating at EL3 never has to switch the debug registers between Secure state and Non-secure state.
  - The PE cannot take a debug exception unless it is enabled from the current Exception level. See [Table D2-5 on page D2-1913](#).
  - If either the OS lock or the OS double-lock is locked, debug exceptions other than Breakpoint Instruction exceptions are disabled.
  - If EL3 and EL2 are not implemented, and the implementation is a Secure state only implementation, the PE behaves as if [MDCR\\_EL3.SDD](#) is 0.
- 

## D2.4.2 Pseudocode description of enabling debug exceptions

[AArch64.GenerateDebugExceptions\(\)](#) determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the current Exception level and Security state.

[AArch64.GenerateDebugExceptionsFrom\(\)](#) determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the specified Exception level and Security state.

These functions are described in [Chapter J1 ARMv8 Pseudocode](#).

## D2.5 The effect of powerdown on debug exceptions

*Debug OS Save and Restore sequences on page H6-5541* describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and `DoubleLockStatus() == FALSE`.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.

## D2.6 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

### Breakpoint Instruction exceptions

These are always enabled, regardless of the current Exception level and Security state. [Table D2-7](#) shows the routing of these. In the table, n/a means not applicable.

**Table D2-7 Routing of Breakpoint Instruction exceptions**

Current Security state	MDCR_EL2.TDE <sup>a</sup>	EL <sub>D</sub> when enabled from:			
		EL0	EL1	EL2	EL3
Secure	X	Secure EL1	Secure EL1	n/a	EL3
Non-secure	0	Non-secure EL1	Non-secure EL1	EL2	n/a
	1	EL2	EL2	EL2	n/a

a. If EL2 is not implemented, behavior is as if this is 0. Otherwise, if the value of [HCR\\_EL2.TGE](#) is 1, [MDCR\\_EL2.TDE](#) is treated as being 1 other than for a direct read of [MDCR\\_EL2](#).

### All other debug exceptions

[Table D2-8](#) shows the valid combinations of [MDCR\\_EL3.SDD](#), [MDCR\\_EL2.TDE](#), [MDSCR\\_EL1.KDE](#), and [PSTATE.D](#), and for each combination shows where these exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

**Table D2-8 Routing of Breakpoint, Watchpoint, Software Step, and Vector Catch exceptions**

Debug state	Lock <sup>a</sup>	Current Security state	SDD <sup>b</sup>	TDE <sup>c</sup>	KDE	D	EL <sub>D</sub> when enabled from:			
							EL0	EL1	EL2	EL3
Yes	X	X	X	X	X	X	-	-	-	-
No	TRUE	X	X	X	X	X	-	-	-	-
No	FALSE	Secure	1	X	X	X	-	-	n/a	-
No	FALSE	Secure	0	X	0	X	Secure EL1	-	n/a	-
No	FALSE	Secure	0	X	1	1	Secure EL1	-	n/a	-
No	FALSE	Secure	0	X	1	0	Secure EL1	Secure EL1	n/a	-
No	FALSE	Non-secure	X	0	0	X	Non-secure EL1	-	-	n/a
No	FALSE	Non-secure	X	0	1	1	Non-secure EL1	-	-	n/a
No	FALSE	Non-secure	X	0	1	0	Non-secure EL1	Non-secure EL1	-	n/a
No	FALSE	Non-secure	X	1	0	X	EL2	EL2	-	n/a
No	FALSE	Non-secure	X	1	1	1	EL2	EL2	-	n/a
No	FALSE	Non-secure	X	1	1	0	EL2	EL2	EL2	n/a

a. The value of [\(OSLSR\\_EL1.OSLK == '1' || DoubleLockStatus\(\)\)](#).

b. If EL3 is not implemented, behavior is as if this is 0.

- c. If [HCR\\_EL2.TGE](#) is 1, this bit is treated as being 1 other than for a direct read of [MDCR\\_EL2](#). If EL2 is not implemented, behavior is as if TDE is 0.

## D2.7 Pseudocode description of debug exceptions

`AArch64.DebugFault()` returns a `FaultRecord` object that indicates that a memory access has generated a debug exception:

The `AArch64.Abort()` function processes `FaultRecord` objects, as described in *Abort exceptions on page D3-2002*, and generates a debug exception.

`AArch64.Abort()` calls one of the following:

- `AArch64.BreakpointException()`.
- `AArch64.WatchpointException()`.
- `AArch64.VectorCatchException()`.
- `AArch64.SoftwareStepException()`.

These functions are defined in *Chapter J1 ARMv8 Pseudocode*.

## D2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

For software executing in an Exception level that is using AArch64, a Breakpoint Instruction exception results from the execution of an A64 BRK instruction. However, within the AArch64 EL1&0 translation regime, executing a T32 or A32 BKPT instruction at EL0 using AArch32 generates a Breakpoint Instruction exception.

For more information about the T32 and A32 BKPT instructions, see:

- [Breakpoint instruction in the A32 and T32 instruction sets on page G2-4467.](#)
- [BKPT instructions as the first instruction in an IT block on page G2-4468.](#)

The following subsections describe Breakpoint Instruction exceptions in an AArch64 translation regime:

- [About Breakpoint Instruction exceptions.](#)
- [Breakpoint instructions.](#)
- [Exception syndrome information and preferred return address on page D2-1920.](#)
- [Pseudocode description of Breakpoint Instruction exceptions on page D2-1920.](#)

### D2.8.1 About Breakpoint Instruction exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

*Breakpoint Instruction exceptions*, that this section describes, are software breakpoints. [Breakpoint exceptions on page D2-1921](#) describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the *debug target Exception level*,  $EL_D$ , is using AArch64 or AArch32.

---

#### Note

- The debug target Exception level,  $EL_D$ , is the Exception level that debug exceptions are targeting. [Routing debug exceptions on page D2-1911](#) describes how  $EL_D$  is derived.
  - Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See [Concurrent modification and execution of instructions on page B2-84](#).
- 

### D2.8.2 Breakpoint instructions

The breakpoint instruction in the A64 instruction set is BRK #<immediate>. It is unconditional.

For details of the instruction encoding, see [BRK on page C6-563](#).

The breakpoint instruction in the A32 and T32 instruction sets is BKPT #<immediate>.

For more information about the A32 and T32 breakpoint instruction, see [Breakpoint instruction in the A32 and T32 instruction sets on page G2-4467](#).

### D2.8.3 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address](#).

#### Exception syndrome information

On taking a Breakpoint Instruction exception, the PE records information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- [ESR\\_EL1](#).
- [ESR\\_EL2](#).
- [ESR\\_EL3](#).

———— **Note** ————

Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

[Table D2-9](#) shows the information that the PE records.

**Table D2-9 Information recorded in the [ESR\\_ELx](#)**

<b>ESR_ELx field</b>	<b>Information recorded in <a href="#">ESR_EL1</a>, <a href="#">ESR_EL2</a>, or <a href="#">ESR_EL3</a>.</b>	
<i>Exception Class</i> , EC	Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to: <ul style="list-style-type: none"><li>• 0x3C for an A64 BRK instruction.</li><li>• 0x38 for an A32 or T32 BKPT instruction.</li></ul>	
<i>Instruction Length</i> , IL	The PE sets this to: <ul style="list-style-type: none"><li>• 0 for a 16-bit T32 BKPT instruction.</li><li>• 1 for an A64 BRK instruction, or an A32 BKPT instruction.</li></ul>	
<i>Instruction Specific Syndrome</i> , ISS	<b>ISS[24:16]</b>	RES0.
	<b>ISS[15:0]</b>	The PE copies the instruction Comment field value into here, zero extended as necessary.

———— **Note** ————

- If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Breakpoint Instruction exception is routed to EL2, [ESR\\_EL2.EC](#) is set to the same value as if the exception was taken to EL1.
- For information about how debug exceptions can be routed to EL2, see [Routing debug exceptions on page D2-1911](#).

#### Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

### D2.8.4 Pseudocode description of Breakpoint Instruction exceptions

[AArch64.SoftwareBreakpoint\(\)](#) generates a Breakpoint Instruction exception that is taken to AArch64 state.

This function is defined in [Chapter J1 ARMv8 Pseudocode](#).

## D2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:

- [About Breakpoint exceptions](#).
- [Breakpoint types and linking of breakpoints on page D2-1922](#).
- [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1931](#).
- [Breakpoint instruction address comparisons on page D2-1932](#).
- [Breakpoint context comparisons on page D2-1934](#).
- [Breakpoint usage constraints on page D2-1935](#).
- [Exception syndrome information and preferred return address on page D2-1938](#).
- [Pseudocode description of Breakpoint exceptions taken from AArch64 state on page D2-1939](#).

### D2.9.1 About Breakpoint exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

*Breakpoint exceptions* are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in [Breakpoint Instruction exceptions on page D2-1919](#).

An implementation can include between 2-16 hardware breakpoints. [ID\\_AA64DFR0\\_EL1](#).BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, [DBGBCR<n>\\_EL1](#). This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, [DBGBVR<n>\\_EL1](#). This holds the value used for breakpoint matching, that is one of:
  - An instruction virtual address.
  - A Context ID.
  - A [VMID](#) value.
  - A concatenation of both a Context ID value and a [VMID](#) value.

These registers are numbered, so that:

- [DBGBCR1\\_EL1](#) and [DBGBVR1\\_EL1](#) are for breakpoint number one.
- [DBGBCR2\\_EL1](#) and [DBGBVR2\\_EL1](#) are for breakpoint number two.
- ...
- ...
- [DBGBCR<n>\\_EL1](#) and [DBGBVR<n>\\_EL1](#) are for breakpoint number n.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, `DBGBCR<n>_EL1.E`, is 1.
- The conditions specified in the `DBGBCR<n>_EL1` are met.
- The comparison with the value held in the `DBGBVR<n>_EL1` is successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its Condition code check.
- The instruction type.

If halting is allowed and `EDSCR.HDE` is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Breakpoint debug events generate Breakpoint exceptions.
- Disabled, Breakpoint debug events are ignored.

———— **Note** ————

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

*The debug exception enable controls on page D2-1910 describes the enable controls for Breakpoint debug events.*

## D2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match.
  - A Context ID match, with the value held in the `CONTEXTIDR_EL1`.
  - A `VMID` match, with the `VMID` value held in the `VTTBR_EL2`.
  - Both a Context ID match and a `VMID` match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match.

`ID_AA64DFR0_EL1.CTX_CMPs` shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an *Unlinked breakpoint*.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a *Linked breakpoint*.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match occurs. For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Linked Context ID Match breakpoint*.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* field for a breakpoint, `DBGBCR<n>_EL1.BT`, controls the breakpoint type and whether the breakpoint is enabled for linking. If `BT[0]` is 1, the breakpoint is enabled for linking.

Figure D2-1 shows all of the possible breakpoint types that stage 1 of an AArch64 translation regime supports, and their associated BT field values.

		Unlinked	Linked
Address breakpoints	Address Match	BT == 0b0000 Unlinked Address Match	BT == 0b0001 Linked Address Match
Context breakpoints	Context ID Match	BT == 0b0010 Unlinked Context ID Match	BT == 0b0011 Linked Context ID Match
	VMID Match	BT == 0b1000 Unlinked VMID Match	BT == 0b1001 Linked VMID Match
	VMID and context ID Match	BT == 0b1010 Unlinked VMID and Context ID Match	BT == 0b1011 Linked VMID and Context ID Match

**Figure D2-1 Breakpoint types and their associated BT field values**

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See [Specifying the halfword-aligned address that an Address breakpoint matches on on page D2-1933](#).

#### **Note**

Stage 1 of an AArch32 translation regimes supports two additional breakpoint types, Unlinked and Linked Address Mismatch breakpoints, `BT == 0b0100` and `BT == 0b0101`. For information about these, see [Chapter G2 AArch32 Self-hosted Debug](#). These types are reserved in stage 1 of an AArch64 translation regime. See [Reserved BT values on page D2-1935](#).

## Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGBCR<n>_EL1.LBN`, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  - `DBGBCR<n>_EL1.{SSC, HMC, PMC}` for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1931](#).
  - `DBGBCR<n>_EL1.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See [Other usage constraints for Address breakpoints on page D2-1938](#).
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

### **Note**

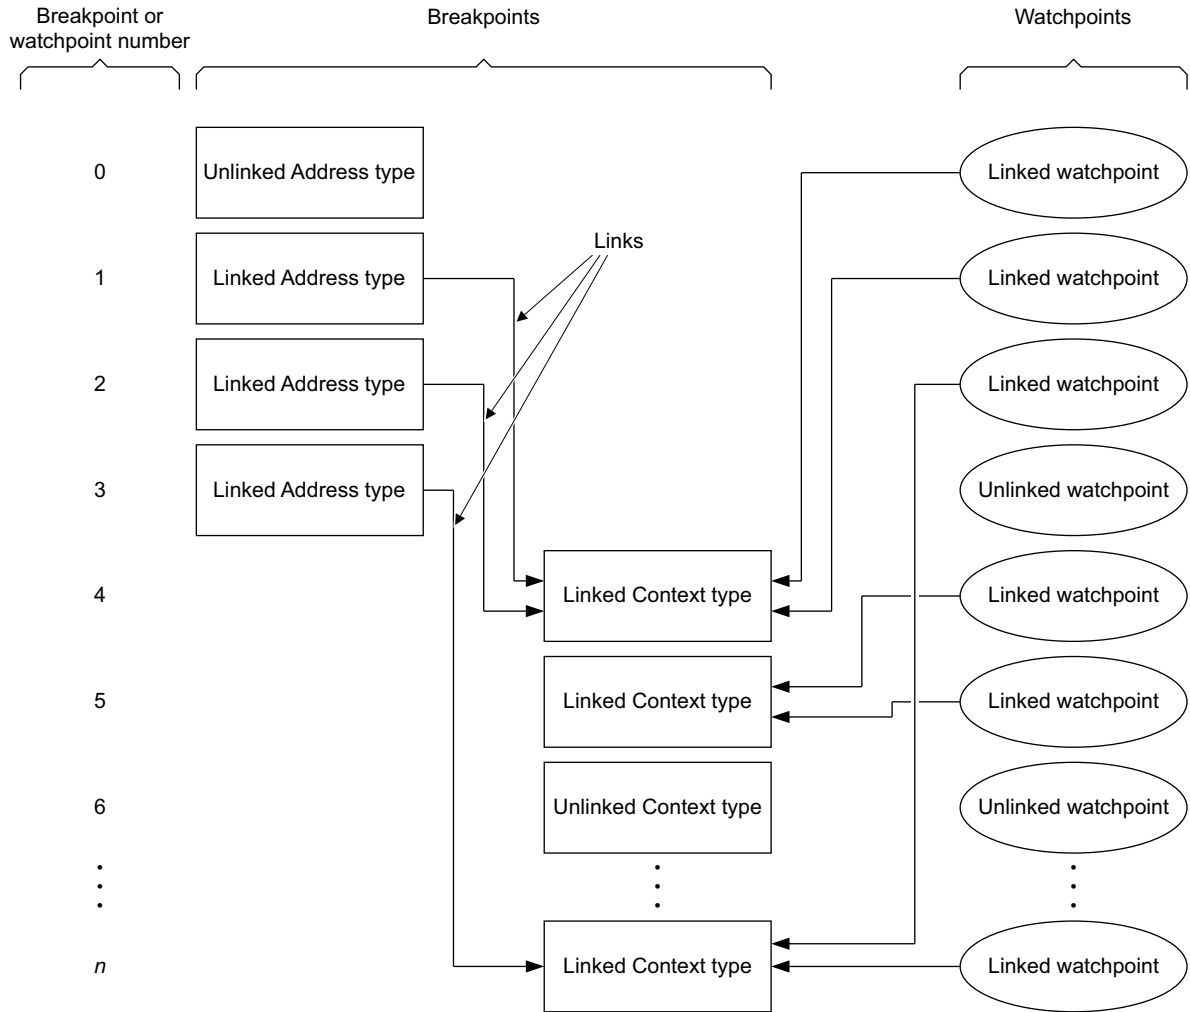

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. [Watchpoint exceptions on page D2-1940](#) describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

[Figure D2-2 on page D2-1925](#) shows an example of permitted breakpoint and watchpoint linking.

**Figure D2-2 The role of linking in Breakpoint and Watchpoint exception generation**

In [Figure D2-2](#), each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links, to are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

### Breakpoint types defined by DBGBCR<sub>n</sub>\_EL1.BT

The following list provides more detail about each breakpoint type:

#### 0b0000, Unlinked Address Match breakpoint

Generation of a Breakpoint exception depends on both:

- [DBGBCR<n>\\_EL1.{SSC, HMC, PMC}](#). These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1931](#).
- A successful address match, as described in [Breakpoint instruction address comparisons on page D2-1932](#).

[DBGBCR<n>\\_EL1.LBN](#) for this breakpoint is ignored.

#### 0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>\_EL1**. {SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1931](#).
- A successful address match defined by this breakpoint, as described in [Breakpoint instruction address comparisons on page D2-1932](#).
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

**DBGBCR<n>\_EL1.LBN** for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

#### 0b0010, Unlinked Context ID Match breakpoint

BT = 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>\_EL1**. {SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1931](#).
- A successful Context ID match, as described in [Breakpoint context comparisons on page D2-1934](#).

The value of **DBGBCR<n>\_EL1.ContextID** is compared with the current Context ID.

**CONTEXTIDR\_EL2** holds the current Context ID when all of:

- The implementation includes [ARMv8.1-VHE](#).
- The PE is in Non-secure state.
- EL2 using AArch64 and **HCR\_EL2.E2H** is set to 1.
- The PE is executing at EL0 and **HCR\_EL2.TGE** is 1, or the PE is executing at EL2.

Otherwise, **CONTEXTIDR\_EL1** holds the current Context ID.

**DBGBCR<n>\_EL1**. {LBN, BAS} for this breakpoint are ignored

#### 0b0011, Linked Context ID Match breakpoint

BT = 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons on page D2-1932](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-1934](#).
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page D2-1944](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-1934](#).

The value of **DBGBCR<n>\_EL1.ContextID** is compared with the current Context ID.

**CONTEXTIDR\_EL2** holds the current Context ID when all of:

- The implementation includes [ARMv8.1-VHE](#).
- The PE is in Non-secure state.
- EL2 using AArch64 and **HCR\_EL2.E2H** is set to 1.

- The PE is executing at EL0 and [HCR\\_EL2.TGE](#) is 1, or the PE is executing at EL2.

Otherwise, [CONTEXTIDR\\_EL1](#) holds the current Context ID.

[DBGBCR<n>\\_EL1](#).{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

#### 0b0100, Unlinked Address Mismatch breakpoint

BT = 0b0100 is a reserved value in stage 1 of an AArch64 translation regime. See [Reserved BT values on page D2-1935](#).

[0b0100, Unlinked Address Mismatch breakpoint on page G2-4476](#) describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

#### 0b0101, Linked Address Mismatch breakpoint

BT = 0b0101 is a reserved value in stage 1 of an AArch64 translation regime. See [Reserved BT values on page D2-1935](#).

[0b0101, Linked Address Mismatch breakpoint on page G2-4476](#) describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

#### 0b0110, Unlinked CONTEXTIDR\_EL1 Match

BT = 0b0110 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- [DBGBCR<n>\\_EL1](#).{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-1934](#).

The Context ID check is made against the value in [CONTEXTIDR\\_EL1](#). The value of [DBGBVR<n>\\_EL1.ContextID](#) is compared with the Context ID value held in [CONTEXTIDR\\_EL1](#).

[DBGBCR<n>\\_EL1](#).{LBN, BAS} for this breakpoint are ignored.

#### 0b0111, Linked CONTEXTIDR\_EL1 Match

BT = 0b0111 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons on page D2-1932](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-1934](#).
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page D2-1944](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-1934](#).

The Context ID check is made against the value in [CONTEXTIDR\\_EL1](#). The value of [DBGBVR<n>\\_EL1.ContextID](#) is compared with the Context ID value held in [CONTEXTIDR\\_EL1](#).

**DBGBCR<n>\_EL1**.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

#### 0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>\_EL1**.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See *Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1931*.
- A successful VMID match, as described in *Breakpoint context comparisons on page D2-1934*.

**DBGBCR<n>\_EL1**.{LBN, BAS} for this breakpoint are ignored.

#### 0b1001, Linked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See *Breakpoint instruction address comparisons on page D2-1932*.
  - A successful VMID match defined by this breakpoint, as described in *Breakpoint context comparisons on page D2-1934*.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons on page D2-1944*.
  - A successful VMID match defined by this breakpoint, as described in *Breakpoint context comparisons on page D2-1934*.

**DBGBCR<n>\_EL1**.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

#### 0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>\_EL1**.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1931*.
- A successful Context ID match, as described in *Breakpoint context comparisons on page D2-1934*.
- A successful VMID match.

The value of **DBGBVR<n>\_EL1.ContextID** is compared with the current Context ID.

**CONTEXTIDR\_EL2** holds the current Context ID when all of:

- The implementation includes **ARMv8.1-VHE**.
- The PE is in Non-secure state.
- EL2 using AArch64 and **HCR\_EL2.E2H** is set to 1.

- The PE is executing at EL0 and [HCR\\_EL2.TGE](#) is 1, or the PE is executing at EL2.

Otherwise, [CONTEXTIDR\\_EL1](#) holds the current Context ID.

[Breakpoint context comparisons on page D2-1934](#) describes the requirements for a successful Context ID match and a successful [VMID](#) match.

[DBGBCR<n>\\_EL1](#).{LBN, BAS} for this breakpoint are ignored.

#### 0b1011, Linked Context ID and VMID Match breakpoint

BT == 0b1011 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on all of the following:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons on page D2-1932](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-1934](#).
  - A successful [VMID](#) match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page D2-1944](#).
  - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-1934](#).
  - A successful [VMID](#) match defined by this breakpoint.

The value of [DBGBVR<n>\\_EL1.ContextID](#) is compared with the current Context ID.

[CONTEXTIDR\\_EL2](#) holds the current Context ID when all of:

- The implementation includes [ARMv8.1-VHE](#).
- The PE is in Non-secure state.
- EL2 using AArch64 and [HCR\\_EL2.E2H](#) is set to 1.
- The PE is executing at EL0 and [HCR\\_EL2.TGE](#) is 1, or the PE is executing at EL2.

Otherwise, [CONTEXTIDR\\_EL1](#) holds the current Context ID.

[Breakpoint context comparisons on page D2-1934](#) describes the requirements for a successful Context ID match and a successful [VMID](#) match by this breakpoint.

[DBGBCR<n>\\_EL1](#).{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

#### 0b1100, Unlinked CONTEXTIDR\_EL2 Match

BT == 0b1100 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- [DBGBCR<n>\\_EL1](#).{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful [CONTEXTIDR\\_EL2](#) match, as described in [Breakpoint context comparisons on page D2-1934](#).

The Context ID check is made against the value in [CONTEXTIDR\\_EL2](#). The value of [DBGBVR<n>\\_EL1](#) is compared with the Context ID value held in [CONTEXTIDR\\_EL2](#).

[DBGBCR<n>\\_EL1](#).{LBN, BAS} for this breakpoint are ignored.

#### 0b1101, Linked CONTEXTIDR\_EL2 Match

BT == 0b1101 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons](#) on page D2-1932.
  - A successful [CONTEXTIDR\\_EL2](#) match, as described in [Breakpoint context comparisons](#) on page D2-1934.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons](#) on page D2-1944.
  - A successful [CONTEXTIDR\\_EL2](#) match, as described in [Breakpoint context comparisons](#) on page D2-1934.

The Context ID check is made against the value in [CONTEXTIDR\\_EL2](#). The value of [DBGBVR<n>\\_EL1](#) is compared with the Context ID value held in [CONTEXTIDR\\_EL2](#). [DBGBCR<n>\\_EL1](#).{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

#### 0b1110, Unlinked Full Context ID Match

BT == 0b1110 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- [DBGBCR<n>\\_EL1](#).{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in [Breakpoint context comparisons](#) on page D2-1934.

The Context ID check is made against the values in both [CONTEXTIDR\\_EL1](#) and [CONTEXTIDR\\_EL2](#). The value of [DBGBVR<n>\\_EL1](#)[31:0] is compared with the Context ID value held in [CONTEXTIDR\\_EL1](#), and the value of [DBGBVR<n>\\_EL1](#)[63:32] is compared with the Context ID value held in [CONTEXTIDR\\_EL2](#). Both comparisons must match for the Context ID check.

[DBGBCR<n>\\_EL1](#).{LBN, BAS} for this breakpoint are ignored.

#### 0b1111, Linked Full Context ID Match

BT == 0b1111 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include [ARMv8.1-VHE](#).

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons](#) on page D2-1932.
  - A successful Context ID match, as described in [Breakpoint context comparisons](#) on page D2-1934.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page D2-1944](#).
  - A successful Context ID match, as described in [Breakpoint context comparisons on page D2-1934](#).

The Context ID check is made against the values in both `CONTEXTIDR_EL1` and `CONTEXTIDR_EL2`. The value of `DBGBVR<n>_EL1[31:0]` is compared with the Context ID value held in `CONTEXTIDR_EL1`, and the value of `DBGBVR<n>_EL1[63:32]` is compared with the Context ID value held in `CONTEXTIDR_EL2`. Both comparisons must match for the Context ID check.

`DBGBCR<n>_EL1`. {LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

---

**Note**

See [Reserved `DBGBCR<n>\_EL1.BT` values on page D2-1935](#) for the behavior of breakpoints programmed with reserved BT values.

---

### D2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

`DBGBCR<n>_EL1`. {SSC, HMC, PMC} defines the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

#### Security State Control, SSC

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

---

**Note**

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

---

#### Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint exceptions in.

[Table D2-10 on page D2-1932](#) shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Exception levels breakpoints generate Breakpoint exceptions in.

In the table:

- Y or -** Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row:
- Y** Can generate Breakpoint exceptions in that Exception level.
  - Cannot generate Breakpoint exceptions in that Exception level.
- Res** Means that the combination of HMC, SSC, and PMC is reserved. See [Reserved `DBGBCR<n>\_EL1`. {SSC, HMC, PMC} values on page D2-1936](#).

Table D2-10 Summary of breakpoint HMC, SSC, and PMC encodings

HMC	SSC	PMC	Security state the breakpoint is programmed to match in	EL3 <sup>a</sup>	EL2	EL1	EL0	Implementation	
								No EL3	No EL3 and no EL2
0	00	01	Both	-	-	Y	-	-	-
0	00	10		-	-	-	Y	-	-
0	00	11		-	-	Y	Y	-	-
0	01	01	Non-secure	-	-	Y	-	Res	Res
0	01	10		-	-	-	Y	Res	Res
0	01	11		-	-	Y	Y	Res	Res
0	10	01	Secure	-	-	Y	-	Res	Res
0	10	10		-	-	-	Y	Res	Res
0	10	11		-	-	Y	Y	Res	Res
1	00	01	Both	Y	Y	Y	-	-	Res
1	00	11		Y	Y	Y	Y	-	Res
1	01	01	Non-secure	-	Y	Y	-	Res	Res
1	01	11		-	Y	Y	Y	Res	Res
1	10	00	Secure	Y	-	-	-	Res	Res
1	10	01		Y	-	Y	-	Res	Res
1	10	11		Y	-	Y	Y	Res	Res
1	11	00	Non-secure	-	Y	-	-	-	Res if no EL2 <sup>b</sup>

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.

b. This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See [Reserved DBGBCR<n>\\_EL1.{SSC, HMC, PMC} values on page D2-1936](#).

## D2.9.4 Breakpoint instruction address comparisons

In this subsection, the term `maxAddressSize` represents the maximum supported virtual address size, which is **52 bits in an implementation that includes ARMv8.2-LVA and uses the 64KB translation granule and 48 bits otherwise**.

An address comparison is successful if bits [`maxAddressSize:2`] of the current instruction virtual address are equal to `DBGBVR<n>_EL1[maxAddressSize:2]`.

### ———— Note —————

`DBGBVR<n>_EL1` is a 64-bit register. The most significant bits of this register are sign-extension bits. `DBGBVR<n>_EL1[1:0]` are RES0 and are ignored.

If EL1 is using AArch64 and EL0 is using AArch32, A32 and T32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.

Specifying the halfword-aligned address that an Address breakpoint matches on

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger must program the *Byte Address Selection* field, `DBGBCR<n>_EL1.BAS`.

Table D2-11 Programmable BAS values

BAS	Match instruction at	Constraint for debuggers
0b0011	DBGBCR<n>_EL1	Use for T32 instructions.
0b1100	DBGBCR<n>_EL1 + 2	Use for T32 instructions.
0b1111	DBGBCR<n>_EL1	Use for A64 and A32 instructions.

If the implementation is an AArch64-only implementation, all instructions are word-aligned and `DBGBCR<n>_EL1.BAS` is RES1.

Figure D2-3 on page D2-1934 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with `DBGBCR<n>_EL1.BAS` programmed as either 0b0011 or 0b1111 generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

———— **Note** —————

To breakpoint on an A64 instruction, ARM recommends that the debugger programs `DBGBCR<n>_EL1.BAS` as 0b1111.

In the figure:

- Yes** Means that the breakpoint generates a Breakpoint exception.
- No** Means that the breakpoint does not generate a Breakpoint exception.
- UNP** Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See *Other usage constraints for Address breakpoints on page D2-1938*.

	Instruction set	Size	Location of instruction <sup>a</sup>								BAS[3:0]		
			-2	-1	0	+1	+2	+3	+4	+5	0b0011	0b1100	0b1111
Row 1	T32	16-bit									Yes	No	Yes
Row 2		16-bit									No	Yes	UNP
Row 3	T32	32-bit									UNP	No	UNP
Row 4		32-bit									Yes	UNP	Yes
Row 5		32-bit									No	Yes	UNP
Row 6	A32	32-bit									Yes	UNP	Yes
Row 7	A64	32-bit									Yes	UNP	Yes

- a. 0 means the word-aligned address held in the `DBGVCR<n>_EL1`[maxAddressSize:2]:00. The other locations are:
- 2 means  $((\text{DBGVCR}\langle n \rangle\_EL1[\text{maxAddressSize}:2]:00) - 2)$ .
  - 1 means  $((\text{DBGVCR}\langle n \rangle\_EL1[\text{maxAddressSize}:2]:00) - 1)$ .
  - ...
  - ...
  - +5 means  $((\text{DBGVCR}\langle n \rangle\_EL1[\text{maxAddressSize}:2]:00) + 5)$ .

The solid areas show the location of the instruction.

**Figure D2-3 Summary of BAS field meanings for Address Match breakpoints**

## D2.9.5 Breakpoint context comparisons

The breakpoint type defined by `DBGVCR<n>_EL1.BT` determines what context comparison is required, if any. [Table D2-12](#) shows the BT values that require a comparison, and the match required for the comparison to be successful.

**Table D2-12 Breakpoint context comparison tests**

<code>DBGVCR&lt;n&gt;_BT</code>	Test required for successful context comparison
0b001x	When ARMv8.1-VHE is not implemented, <code>CONTEXTIDR_EL1</code> value matches <code>DBGVCR&lt;n&gt;_EL1.ContextID</code> value
	When ARMv8.1-VHE is implemented, <code>CONTEXTIDR_EL2</code> matches <code>DBGVCR&lt;n&gt;_EL1.ContextID</code> value
0b011x	<code>CONTEXTIDR_EL1</code> value matches <code>DBGVCR&lt;n&gt;_EL1.ContextID</code> value
0b100x	<code>VTTBR_EL2.VMID</code> value matches <code>DBGVCR&lt;n&gt;_EL1.VMID</code> value
0b101x	When ARMv8.1-VHE is not implemented, <code>CONTEXTIDR_EL1</code> value matches <code>DBGVCR&lt;n&gt;_EL1.ContextID</code> value and <code>VTTBR_EL2.VMID</code> value matches <code>DBGVCR&lt;n&gt;_EL1.VMID</code> value
	When ARMv8.1-VHE is implemented, <code>CONTEXTIDR_EL2</code> matches <code>DBGVCR&lt;n&gt;_EL1.ContextID</code> value and <code>VTTBR_EL2.VMID</code> value matches <code>DBGVCR&lt;n&gt;_EL1.VMID</code> value
0b110x	<code>CONTEXTIDR_EL2</code> value matches <code>DBGVCR&lt;n&gt;_EL1.ContextID</code> value
0b111x	<code>CONTEXTIDR_EL1</code> value matches <code>DBGVCR&lt;n&gt;_EL1[63:32]</code> and <code>CONTEXTIDR_EL2</code> value matches <code>DBGVCR&lt;n&gt;_EL1[31:0]</code>

No context comparison is required for other valid `DBGVCR<n>_BT` values.

In ARMv8.0, context breakpoints do not generate Breakpoint exceptions when execution is in EL2 using either Execution state, or when execution is in EL3 using AArch64.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of `CONTEXTIDR_EL1` and any of:
  - The PE is executing at EL3 using AArch64.
  - The PE is executing at EL2.
  - [ARMv8.1-VHE](#) is implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and `HCR_EL2.{E2H, TGE} == {1, 1}`.
- The comparison uses the value of `CONTEXTIDR_EL2` and any of:
  - [ARMv8.1-VHE](#) is not implemented.
  - The PE is in Secure state.
  - EL2 is using AArch32.
- The comparison uses the current `VMID` value and any of:
  - EL2 is not implemented.
  - The PE is in Secure state.
  - The PE is executing at EL2.
  - [ARMv8.1-VHE](#) is implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and `HCR_EL2.{E2H, TGE} == {1, 1}`.

The following Context breakpoint types do not generate Breakpoint exceptions in Secure state:

- `VMID` Match breakpoints.
- `VMID` and Context ID Match breakpoints.

#### ————— Note —————

- For all Context breakpoints, `DBGBCR<n>_EL1.BAS` is RES1 and is ignored.
- For Linked Context breakpoints, `DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC}` are RES0 and are ignored.

## D2.9.6 Breakpoint usage constraints

See the following sections:

- [Reserved `DBGBCR<n>\_EL1.BT` values.](#)
- [Reserved `DBGBCR<n>\_EL1.{SSC, HMC, PMC}` values on page D2-1936.](#)
- [Reserved `DBGBCR<n>\_EL1.BAS` values on page D2-1937.](#)
- [Reserved `DBGBCR<n>\_EL1.LBN` values on page D2-1937.](#)
- [Other usage constraints for Address breakpoints on page D2-1938.](#)
- [Other usage constraints for Context breakpoints on page D2-1938.](#)

### Reserved `DBGBCR<n>_EL1.BT` values

[Table D2-13](#) shows when particular `DBGBCR<n>_EL1.BT` values are reserved.

**Table D2-13 Reserved BT values**

BT value	Breakpoint type	Reserved
0b001x	Context ID Match	For non context-aware breakpoints
0b010x	Address Mismatch	In stage 1 of an AArch64 translation regime, or if <code>EDSCR.HDE</code> is 1 and halting is allowed
0b011x	-	In ARMv8.0, always
	CONTEXTIDR_EL1 Match	For non context-aware breakpoints, or if <a href="#">ARMv8.1-VHE</a> is not implemented

**Table D2-13 Reserved BT values (continued)**

BT value	Breakpoint type	Reserved
0b100x	VMID Match	For non context-aware breakpoints, or if EL2 is not implemented
0b101x	Context ID and VMID Match	For non context-aware breakpoints, or if EL2 is not implemented, or if ARMv8.1-VHE is not implemented
0b11xx	-	In ARMv8.0, always
	CONTEXTIDR_EL2 Match	For non context-aware breakpoints, or if ARMv8.1-VHE is not implemented
0b111x	Full Context ID Match	For non context-aware breakpoints, or if ARMv8.1-VHE is not implemented

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<n>\_EL1.
- For a direct or external read of DBGBCR<n>\_EL1, if the reserved BT value:
  - Has no function for any execution conditions, the value read back is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

### Reserved DBGBCR<n>\_EL1.{SSC, HMC, PMC} values

Table D2-14 shows when particular combinations of DBGBCR<n>\_EL1.{SSC, HMC, PMC} are reserved in stage 1 of an AArch64 translation regime.

**Table D2-14 Reserved HMC, SSC, and PMC combinations**

HMC, SSC, and PMC combination	Reserved
All combinations with SSC set to 0b01 or 0b10	When EL3 is not implemented and EL2 is implemented
Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00	When both of EL2 and EL3 are not implemented
The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00	When EL2 is not implemented
Combinations not included in Table D2-10 on page D2-1932	Always

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.

- A direct or external read of `DBGBCR<n>_EL1`.{SSC, HMC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.
- If the reserved combination does not have a function for other execution conditions:
  - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct or external read of `DBGBCR<n>_EL1`.{SSC, HMC, PMC} returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.
- A direct or external read of `DBGBCR<n>_EL1`.{SSC, HMC, PMC} returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

### Reserved `DBGBCR<n>_EL1.BAS` values

In an AArch64-only implementation, `DBGBCR<n>_EL1.BAS` for all breakpoints is RES1.

Otherwise:

#### For all Context breakpoints

`DBGBCR<n>_EL1.BAS` is RES1 and is ignored.

#### For all Address breakpoints

[Table D2-11 on page D2-1933](#) gives the valid values of the `DBGBCR<n>_EL1.BAS` field.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BAS value that is not reserved, other than for a direct or external read of `DBGBCR<n>_EL1`.
- A direct or external read of `DBGBCR<n>_EL1.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

### Reserved `DBGBCR<n>_EL1.LBN` values

#### For all Context breakpoints

`DBGBCR<n>_EL1.LBN` reads UNKNOWN and its value is ignored.

#### For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any `DBGBCR<n>_EL1.LBN` value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of `DBGBCR<n>_EL1.LBN` return an UNKNOWN value and behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

#### For Unlinked Address breakpoints

[DBGBCR<n>\\_EL1](#).LBN reads UNKNOWN and its value is ignored.

#### Other usage constraints for Address breakpoints

##### For all Address breakpoints

- [DBGBVR<n>\\_EL1](#)[1:0] are RES0 and are ignored.
- If the implementation supports AArch32 state:
  - For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
  - If [DBGBCR<n>](#).BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address  $((\text{DBGBVR}\langle n \rangle[48:2]:00) + 2)$ . For T32 instructions, ARM recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

#### Other usage constraints for Context breakpoints

##### For all Context breakpoints

Any bits of [DBGBVR<n>\\_EL1](#) that are not used to specify Context ID or [VMID](#) are RES0 and are ignored.

##### For Linked Context breakpoints

If no Linked Address breakpoints or Linked watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

## D2.9.7 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address on page D2-1939](#).

### Exception syndrome information

On taking a Breakpoint exception, the PE records information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- [ESR\\_EL1](#).
- [ESR\\_EL2](#).

#### ———— Note ————

Breakpoint exceptions cannot be taken to EL3 using AArch64.

Table D2-15 shows the information that the PE records.

**Table D2-15 Information recorded in the ESR\_ELx**

ESR_ELx field	Information recorded in ESR_EL1 or ESR_EL2.	
<i>Exception Class</i> , EC	The PE sets this to: <ul style="list-style-type: none"> <li>0x30, if the exception was taken from a lower Exception level.</li> <li>0x31, if the exception was taken without a change of Exception level.</li> </ul>	
<i>Instruction Length</i> , IL	The PE sets this to 1.	
<i>Instruction Specific Syndrome</i> , ISS	<b>ISS[24:6]</b>	RES0.
	<b>ISS[5:0]</b>	<i>Instruction Fault Status Code</i> (IFSC). The PE sets this to the code for a debug exception, 0b100010.

### Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

## D2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch64 state

[AArch64.BreakpointValueMatch\(\)](#) tests the value in [DBGBVR<n>\\_EL1](#).

[AArch64.StateMatch\(\)](#) tests the values in [DBGBCR<n>\\_EL1](#). {SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

For a watchpoint, [AArch64.StateMatch\(\)](#) tests the values in [DBGWCR<n>\\_EL1](#). {SSC, HMC, PAC} and, if the watchpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

[AArch64.BreakpointMatch\(\)](#) tests a committed instruction against all breakpoints.

[AArch64.CheckBreakpoint\(\)](#) generates a Breakpoint exception if all of the following are true:

- [MDSCR\\_EL1](#).MDE is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level and Security state](#) on page D2-1913.
- All of the conditions required for Breakpoint exception generation are met. See [About Breakpoint exceptions](#) on page D2-1921.

### ———— Note ————

[AArch64.CheckBreakpoint\(\)](#) might halt the PE and cause it to enter Debug state. External debug uses Debug state.

[AArch64.BreakpointException\(\)](#) is called to generate a Breakpoint exception.

These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

## D2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:

- [About Watchpoint exceptions.](#)
- [Watchpoint types and linking of watchpoints on page D2-1942.](#)
- [Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-1943.](#)
- [Watchpoint data address comparisons on page D2-1944.](#)
- [Determining the memory location that caused a Watchpoint exception on page D2-1948.](#)
- [Watchpoint behavior on other instructions on page D2-1949.](#)
- [Watchpoint usage constraints on page D2-1950.](#)
- [Exception syndrome information and preferred return address on page D2-1952.](#)
- [Pseudocode description of Watchpoint exceptions taken from AArch64 state on page D2-1953.](#)

### D2.10.1 About Watchpoint exceptions

A *watchpoint* is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, [ID\\_AA64DFR0\\_EL1](#).WRPs shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, [DBGWCR<n>\\_EL1](#). This contains controls for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, [DBGWVR<n>\\_EL1](#). This holds the data virtual address used for watchpoint matching.

These registers are numbered, so that:

- [DBGWCR1\\_EL1](#) and [DBGWVR1\\_EL1](#) are for watchpoint number one.
- [DBGWCR2\\_EL1](#) and [DBGWVR2\\_EL1](#) are for watchpoint number two.
- ...
- ...
- [DBGWCR<n>\\_EL1](#) and [DBGWVR<n>\\_EL1](#) are for watchpoint number n.

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Linked Context breakpoint*, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.

A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, `DBGWCR<n>_EL1.BAS`, to select the bytes. See *Programming a watchpoint with eight bytes or fewer* on page D2-1946.
- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.
 A debugger uses the *MASK* field, `DBGWCR<n>_EL1.MASK`, to program a watchpoint with eight bytes to 2GB. See *Programming a watchpoint with eight or more bytes* on page D2-1947.

A debugger must use either the *BAS* field or the *MASK* field. If it uses both, whether the watchpoint generates Watchpoint debug events is CONSTRAINED UNPREDICTABLE. See *Programming dependencies of the BAS and MASK fields* on page D2-1951.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, `DBGWCR<n>_EL1.E`, is 1.
- The conditions specified in the `DBGWCR<n>_EL1` are met.
- The comparison with the address held in the `DBGWVR<n>_EL1` is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint also are successful. See *Figure D2-2* on page D2-1925. See also *Breakpoint context comparisons* on page D2-1934.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.

If halting is allowed and `EDSCR.HDE` is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

#### ———— **Note** ————

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

*The debug exception enable controls* on page D2-1910 describes the enable controls for Watchpoint debug events.

## D2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the **VMID** matches.

The *Watchpoint Type* field for a watchpoint, **DBGWCR<n>\_EL1.WT**, controls whether the watchpoint is enabled for linking. If **DBGWCR<n>\_EL1.WT** is 1, the watchpoint is enabled for linking.

### Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, **DBGWCR<n>\_EL1.LBN**, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  - **DBGWCR<n>\_EL1.WT**.{SSC, HMC, PAC} for the Linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See [Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-1943](#).
  - **DBGBCR<n>\_EL1**.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See [Watchpoint usage constraints on page D2-1950](#).
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

#### **Note**

Multiple Address breakpoints can also link to a single Linked Context breakpoint. [Breakpoint exceptions on page D2-1921](#) describes breakpoints.

Figure D2-2 on page D2-1925 shows an example of permitted watchpoint linking.

### D2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2 in Non-secure state.

[DBGWCR<n>\\_EL1](#), {SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

#### Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

##### Note

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

#### Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Exception levels the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level at which the access was made.

##### Note

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at EL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on EL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A64 Load unprivileged and Store unprivileged instructions are LDTR and STTR.

[Table D2-16 on page D2-1944](#) shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

<b>Y or -</b>	Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
<b>Y</b>	Can generate Watchpoint exceptions in that Exception level.
<b>-</b>	Cannot generate Watchpoint exceptions in that Exception level.
<b>Res</b>	Means that the combination of HMC, SSC, and PAC is reserved. See <a href="#">Reserved DBGWCR&lt;n&gt;_EL1</a> , {SSC, HMC, PAC} values on page D2-1950.

Table D2-16 Summary of watchpoint HMC, SSC, and PAC encodings

HMC	SSC	PAC	Security state the watchpoint is programmed to match in	EL3 <sup>a</sup>	EL2	EL1	EL0	Implementation	
								No EL3	No EL3 and no EL2
0	00	01	Both	-	-	Y	-	-	-
0	00	10		-	-	-	Y	-	-
0	00	11		-	-	Y	Y	-	-
0	01	01	Non-secure	-	-	Y	-	Res	Res
0	01	10		-	-	-	Y	Res	Res
0	01	11		-	-	Y	Y	Res	Res
0	10	01	Secure	-	-	Y	-	Res	Res
0	10	10		-	-	-	Y	Res	Res
0	10	11		-	-	Y	Y	Res	Res
1	00	01	Both	Y	Y	Y	-	-	Res
1	00	11		Y	Y	Y	Y	-	Res
1	01	01	Non-secure	-	Y	Y	-	Res	Res
1	01	11		-	Y	Y	Y	Res	Res
1	10	00	Secure	Y	-	-	-	Res	Res
1	10	01		Y	-	Y	-	Res	Res
1	10	11		Y	-	Y	Y	Res	Res
1	11	00	Non-secure	-	Y	-	-	-	Res if no EL2 <sup>b</sup>

- a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Watchpoint exceptions at EL3 using AArch64.
- b. This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See [Reserved DBGWCR<n>\\_EL1.{SSC, HMC, PAC} values on page D2-1950](#).

#### D2.10.4 Watchpoint data address comparisons

In this subsection, the term `maxAddressSize` represents the maximum supported virtual address size, which is **52 bits in an implementation that includes ARMv8.2-LVA and uses the 64KB translation granule and 48 bits otherwise**.

An address comparison is successful if bits [maxAddressSize:2] of the current data virtual address are equal to `DBGWVR<n>_EL1`[maxAddressSize:2], taking into account all of the following:

- The size of the access. See *Size of the data access*.  
If EL1 is using AArch64 and EL0 is using AArch32, AArch32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, data addresses are zero-extended before comparison with the watchpoint.
- The bytes selected by `DBGWVR<n>_EL1.BAS`. See *Programming a watchpoint with eight bytes or fewer* on page D2-1946.
- Any address ranges indicated by `DBGWVR<n>_EL1.MASK`. See *Programming a watchpoint with eight or more bytes* on page D2-1947.

---

**Note**

- `DBGWVR<n>_EL1` is a 64-bit register. The most significant bits of this register are sign-extension bits.
  - `DBGWVR<n>_EL1`[1:0] are RES0 and are ignored
- 

### Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. See [Example D2-1](#).

#### Example D2-1

- 
1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address 0x1009 is accessed.
  2. The PE accesses the unaligned doubleword starting at address 0x1003.

In this scenario, the watchpoint must generate a Watchpoint exception.

---

The size of data accesses initiated by DC ZVA instructions is the DC ZVA block size that `DCZID_EL0.BS` defines.

The size of data accesses initiated by DC IVAC instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that `CTR_EL0.DminLine` defines.
  - 2KB.
- A power-of-two.

For both of these instructions:

- The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.
- The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, *Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction* on page D2-1950.

## Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, `DBGWCR<n>_EL1.BAS`, selects which bytes in the doubleword starting at the address contained in the `DBGWVR<n>_EL1` the watchpoint generates Watchpoint exceptions for.

If the address programmed into the `DBGWVR<n>_EL1` is:

- Doubleword-aligned:
  - All eight bits of `DBGWCR<n>_EL1.BAS` are used, and the descriptions given in Table D2-17 apply.
- Word-aligned but not doubleword-aligned:
  - Only `DBGWCR<n>_EL1.BAS[3:0]` are used, and the descriptions given in Table D2-18 apply. In this case, `DBGWCR<n>_EL1.BAS[7:4]` are RES0.

**Table D2-17 Supported BAS values when the `DBGWVRn_EL1` address alignment is doubleword**

BAS value	Description
0b00000000	Watchpoint never generates a Watchpoint exception.
<code>BAS[0] == 1</code>	Generates a Watchpoint exception if the byte at address <code>DBGWVR&lt;n&gt;_EL1[maxAddressSize<sup>a</sup>:3]:000</code> is accessed.
<code>BAS[1] == 1</code>	Generates a Watchpoint exception if the byte at address <code>DBGWVR&lt;n&gt;_EL1[maxAddressSize<sup>a</sup>:3]:001</code> is accessed.
<code>BAS[2] == 1</code>	Generates a Watchpoint exception if the byte at address <code>DBGWVR&lt;n&gt;_EL1[maxAddressSize<sup>a</sup>:3]:010</code> is accessed.
<code>BAS[3] == 1</code>	Generates a Watchpoint exception if the byte at address <code>DBGWVR&lt;n&gt;_EL1[maxAddressSize<sup>a</sup>:3]:011</code> is accessed.
<code>BAS[4] == 1</code>	Generates a Watchpoint exception if the byte at address <code>DBGWVR&lt;n&gt;_EL1[maxAddressSize<sup>a</sup>:3]:100</code> is accessed.
<code>BAS[5] == 1</code>	Generates a Watchpoint exception if the byte at address <code>DBGWVR&lt;n&gt;_EL1[maxAddressSize<sup>a</sup>:3]:101</code> is accessed.
<code>BAS[6] == 1</code>	Generates a Watchpoint exception if the byte at address <code>DBGWVR&lt;n&gt;_EL1[maxAddressSize<sup>a</sup>:3]:110</code> is accessed.
<code>BAS[7] == 1</code>	Generates a Watchpoint exception if the byte at address <code>DBGWVR&lt;n&gt;_EL1[maxAddressSize<sup>a</sup>:3]:111</code> is accessed.

a. The value of `maxAddressSize` is 48 unless a 52 bit address size is implemented, when the value of `maxAddressSize` is 52.

**Table D2-18 Supported BAS values when the `DBGWVRn_EL1` address alignment is word**

BAS value <sup>a</sup>	Description
0b00000000	Watchpoint never generates a Watchpoint exception
<code>BAS[0] == 1</code>	Generates a Watchpoint exception if byte at address <code>DBGWVR&lt;n&gt;_EL1[maxAddressSize<sup>b</sup>:2]:00</code> is accessed.

**Table D2-18 Supported BAS values when the DBGWVRn\_EL1 address alignment is word**

BAS value <sup>a</sup>	Description
BAS[1] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;_EL1</a> [maxAddressSize <sup>b</sup> :2]:01 is accessed.
BAS[2] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;_EL1</a> [maxAddressSize <sup>b</sup> :2]:10 is accessed.
BAS[3] == 1	Generates a Watchpoint exception if byte at address <a href="#">DBGWVR&lt;n&gt;_EL1</a> [maxAddressSize <sup>b</sup> :2]:11 is accessed.

a. [DBGWCR<n>\\_EL1](#).BAS[7:4] are RES0.

b. The value of maxAddressSize is 48 **unless a 52 bit address size is implemented, when the value of maxAddressSize is 52.**

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see [Other usage constraints on page D2-1952](#).

When programming the BAS field with anything other than 0b11111111, a debugger must program [DBGWCR<n>\\_EL1](#).MASK to be 0b000000. See [Programming dependencies of the BAS and MASK fields on page D2-1951](#).

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the [DBGWVR<n>\\_EL1](#)[maxAddressSize:3]. See [Example D2-1 on page D2-1945](#).

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - [DBGWVR<n>\\_EL1](#) with 0x1000.
  - [DBGWCR<n>\\_EL1](#).BAS to be 0b00001000.
- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  - [DBGWVR<n>\\_EL1](#) with 0x2000.
  - [DBGWCR<n>\\_EL1](#).BAS to be 0b00111000.
- If the address programmed into the [DBGWVR<n>\\_EL1](#) is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program [DBGWCR<n>\\_EL1](#).BAS to be 0b00001111.
  - To generate a Watchpoint exception when any byte in the word starting at address [DBGWVR<n>\\_EL1](#)[31:3]:100 is accessed, program [DBGWCR<n>\\_EL1](#).BAS to be 0b11110000.

#### Note

ARM deprecates programming a [DBGWVR<n>\\_EL1](#) with an address that is not doubleword-aligned.

## Programming a watchpoint with eight or more bytes

A debugger can use the MASK field, [DBGWCR<n>\\_EL1](#).MASK, to program a single watchpoint with a data address range. The range must meet all of the following criteria:

- It is a size that is:
  - A power-of-two.

- A minimum of eight bytes.
- A maximum of 2GB.
- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

<b>MASK</b>	0b00000	No bits are masked.
	0b00001	Reserved.
	0b00010	Reserved.
	0b00011	Three least significant bits are masked.
	0b00100	Four least significant bits are masked.
	0b00101	Five least significant bits are masked.
	...	...
	0b11111	31 least significant bits are masked.

If  $n$  least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address [DBGWVR<n>\\_EL1](#)[maxAddressSize: $n$ ]:000...
- Address [DBGWVR<n>\\_EL1](#)[maxAddressSize: $n$ ]:111...
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between [DBGWVR<n>\\_EL1](#)[maxAddressSize:4]:0000 and [DBGWVR<n>\\_EL1](#)[maxAddressSize:4]:1111, including these addresses.

#### ———— **Note** ————

- The 17 most significant bits cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see [Reserved DBGWCR<n>\\_EL1.MASK values on page D2-1952](#).

When masking address bits, a debugger must both:

- Program [DBGWCR<n>\\_EL1.BAS](#) to be 0b11111111. See [Programming dependencies of the BAS and MASK fields on page D2-1951](#).
- In the [DBGWVR<n>\\_EL1](#), set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see [Other usage constraints on page D2-1952](#).

### D2.10.5 Determining the memory location that caused a Watchpoint exception

On taking a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- [FAR\\_EL1](#), if the exception is taken to EL1.
- [FAR\\_EL2](#), if the exception is taken to EL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the [EDWAR](#).

For more information, see the subsections that follow. These are:

- [Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions on page D2-1949](#)
- [Address recorded for Watchpoint exceptions generated by Data Cache instructions on page D2-1949](#)

## Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions

The address recorded must be both:

- From the inclusive range between:
    - The lowest address accessed by the memory access that triggered the watchpoint.
    - The highest *watchpointed address* accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.
  - Within a naturally-aligned block of memory that is all of the following:
    - A power-of-two size.
    - No larger than the DC ZVA block size.
    - Contains a watchpointed address accessed by the memory access.
- The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

### Example D2-2 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:

- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
- 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.

## Address recorded for Watchpoint exceptions generated by Data Cache instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

## D2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Prefetch memory instructions.
- All data cache maintenance instructions except DC IVAC.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an IMPLEMENTATION DEFINED subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are IMPLEMENTATION DEFINED.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

### ———— Note ————

The DC ZVA instruction is not a data cache maintenance instruction.

See also the following subsections:

- [Watchpoint behavior on accesses by Store-Exclusive instructions on page D2-1950.](#)
- [Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction on page D2-1950.](#)

## Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

## Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction

DC IVAC and DC ZVA operations are treated as data stores. This means that for a watchpoint to match on an access caused by one of these instructions, the debugger must program `DBGWCR<n>_EL1.LSC` to be one of the following:

- 10** Match on data stores.
- 11** Match on data stores and data loads.

### ———— Note ————

For the size of data accesses performed by the DC IVAC instruction and the DC ZVA instruction, see [Watchpoint data address comparisons on page D2-1944](#). The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

## D2.10.7 Watchpoint usage constraints

See the following:

- [Reserved DBGWCR<n>\\_EL1.{SSC, HMC, PAC} values.](#)
- [Reserved DBGWCR<n>\\_EL1.LBN values on page D2-1951.](#)
- [Programming dependencies of the BAS and MASK fields on page D2-1951.](#)
- [Reserved DBGWCR<n>\\_EL1.BAS values on page D2-1951.](#)
- [Reserved DBGWCR<n>\\_EL1.MASK values on page D2-1952.](#)
- [Other usage constraints on page D2-1952.](#)

## Reserved DBGWCR<n>\_EL1.{SSC, HMC, PAC} values

[Table D2-19](#) shows when particular combinations of `DBGWCR<n>_EL1.{SSC, HMC, PAC}` are reserved.

**Table D2-19 Reserved SSC, HMC, and PAC combinations**

HMC, SSC, and PMC combination	Reserved
All combinations with SSC set to 0b01 or 0b10.	When EL3 is not implemented and EL2 is implemented.
All combinations where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00.	When both of EL2 and EL3 are not implemented
The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00.	When EL2 is not implemented
Combinations not included in <a href="#">Table D2-16 on page D2-1944</a> .	Always

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct or external read of `DBGWCR<n>_EL1`.

- For a direct or external read of `DBGWCR<n>_EL1`, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

## Reserved `DBGWCR<n>_EL1.LBN` values

### For Linked Watchpoints

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any `DBGWCR<n>_EL1.LBN` value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of `DBGWCR<n>_EL1.LBN` return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

**For Unlinked Watchpoints** For Unlinked watchpoints, `DBGWCR<n>_EL1.LBN` reads UNKNOWN and its value is ignored.

## Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the `DBGWVR<n>_EL1` the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be `0b11111111`, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be `0b000000`, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is non-zero and a BAS field that is not set to `0b11111111`, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

## Reserved `DBGWCR<n>_EL1.BAS` values

The BAS field must be programmed with a value `Zeros(8-n-m):Ones(n):Zeros(m)`, where:

- $n$  is a non-zero positive integer less-than-or-equal-to 8.
- $m$  is a positive integer less-than 8.
- $n+m$  is less-than-or-equal-to 8.

All other values are reserved.

### ————— Note —————

If  $x$  is zero, then `Zeros(x)` is an empty bitstring.

If `DBGWVR<n>_EL1[2]` is 1, `DBGWCR<n>_EL1.BAS[7:4]` are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the `DBGWVR<n>_EL1`.
- A direct or external read of `DBGWCR<n>_EL1.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

### Reserved `DBGWCR<n>_EL1.MASK` values

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with an UNKNOWN value that is not reserved, that might be `0b00000`, other than for a direct or external read of `DBGWCR<n>_EL1`.
- A direct or external read of `DBGWCR<n>_EL1.MASK` returns an UNKNOWN value.

### Other usage constraints

For all watchpoints:

- `DBGWVR<n>_EL1[1:0]` are RES0 and are ignored.
- If `DBGWCR<n>_EL1.MASK` is nonzero, and any masked bits of `DBGWVR<n>_EL1` are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if `DBGWCR<n>_EL1.LSC` is `0b00`.

## D2.10.8 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address on page D2-1953](#).

### Exception syndrome information

On taking a Watchpoint exception, the PE records all of the following:

- Information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to.
- An address that the debugger can use to determine the memory location that caused the exception. The PE records this in a *Fault Address Register* (FAR).

The ESR and FAR used is either:

- `ESR_EL1` and `FAR_EL1`, if the exception is taken to EL1.
- `ESR_EL2` and `FAR_EL2`, if the exception is taken to EL2.

———— **Note** —————

Watchpoint exceptions cannot be taken to EL3 using AArch64.

Table D2-20 shows the recorded information.

**Table D2-20 Information recorded in the ESR\_ELx**

ESR_ELx field	Information recorded in ESR_EL1 or ESR_EL2	
Exception Class, EC	This is set to: <ul style="list-style-type: none"> <li>0x34, if the exception was taken from a lower Exception level.</li> <li>0x35, if the exception was taken without a change of Exception level.</li> </ul>	
Instruction Length, IL	This is set to 1.	
Instruction Specific Syndrome, ISS	ISS[24]	<i>Instruction Syndrome Valid</i> (ISV). This is 0, because Watchpoint exceptions are not stage 2 aborts.
	ISS[23:9]	RES0.
	ISS[8]	<i>Cache Maintenance</i> (CM). This indicates whether a cache maintenance instruction generated the exception: <ul style="list-style-type: none"> <li>0 Not generated by a cache maintenance instruction.</li> <li>1 Generated by a cache maintenance instruction.</li> </ul> If a DC ZVA instruction generated the exception, CM is 0.
	ISS[7]	RES0.
	ISS[6]	<i>Write-not-Read</i> (WnR). This indicates whether the access was by a read instruction or a write instruction: <ul style="list-style-type: none"> <li>0 Read instruction.</li> <li>1 Write instruction.</li> </ul>
	ISS[5:0]	<i>Data Fault Status Code</i> (DFSC). The PE sets this to the code for a debug exception, 0b100010.

### Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

## D2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch64 state

[AArch64.WatchpointByteMatch\(\)](#) tests an individual byte accessed by an operation.

[AArch64.StateMatch\(\)](#) tests the values in [DBGWCR<n>\\_EL1](#), {HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

[AArch64.WatchpointMatch\(\)](#) tests the value in [DBGWVR<n>\\_EL1](#).

[AArch64.CheckWatchpoint\(\)](#) generates a [FaultRecord](#) that [AArch64.Abort\(\)](#) raises a Watchpoint exception for if all of the following are true:

- [MDSCR\\_EL1.MDE](#) is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level and Security state](#) on page D2-1913.
- All of the conditions required for Watchpoint exception generation are met. See [About Watchpoint exceptions](#) on page D2-1940.

### ———— Note ————

[AArch64.CheckWatchpoint\(\)](#) might halt the PE and cause it to enter Debug state. External debug uses Debug state.

[AArch64.WatchpointException\(\)](#) is called to generate a Watchpoint exception.

These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

## D2.11 Vector Catch exceptions

Vector Catch exceptions are not generated in AArch64 translation regimes.

---

### **Note**

---

This means that they are never taken to EL1 using AArch64 and are only supported if at least EL1 using AArch32 is supported.

---

A debugger that is executing in EL2 using AArch64 can route Vector Catch exceptions to EL2 using AArch64. See [Routing debug exceptions on page D2-1911](#).

`AArch64.VectorCatchException()` is called to generate a Vector Catch exception.

[Vector Catch exceptions on page G2-4510](#) describes Vector Catch exceptions.

## D2.12 Software Step exceptions

The following subsections describe Software Step exceptions:

- [About Software Step exceptions.](#)
- [Rules for setting MDSCR\\_EL1.SS to 1.](#)
- [The software step state machine on page D2-1957.](#)
- [Entering the active-not-pending state on page D2-1958.](#)
- [Behavior in the active-not-pending state on page D2-1962.](#)
- [Entering the active-pending state on page D2-1964.](#)
- [Behavior in the active-pending state on page D2-1964.](#)
- [Stepping T32 IT instructions on page D2-1965.](#)
- [Exception syndrome information and preferred return address on page D2-1965.](#)
- [Additional considerations on page D2-1967.](#)
- [Pseudocode description of Software Step exceptions on page D2-1969.](#)

### D2.12.1 About Software Step exceptions

Software step is an ARMv8-A resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
  - a. Enables software step by setting MDSCR\_EL1.SS to 1. See [The debug exception enable controls on page D2-1910.](#)
  - b. Executes an exception return instruction, ERET, to branch to the instruction to be single-stepped in the software being debugged.
2. The PE then:
  - a. Executes the instruction to be single-stepped.
  - b. Takes a Software Step exception on the next instruction, returning control to the debugger.

However, another exception might be generated while the instruction is being stepped. This exception is either:

- A synchronous exception that is generated by the instruction being stepped.
- An asynchronous exception that is taken before or after the instruction being stepped.

The PE can only take a Software Step exception if debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level and Security state on page D2-1913.](#)

A state machine describes the behavior of software step, shown in [The software step state machine on page D2-1957.](#)

Throughout this [Software Step exceptions](#) section, including in all subsections, EL<sub>D</sub> means the Exception level that Software Step exceptions are targeting. [Routing debug exceptions on page D2-1911](#) defines EL<sub>D</sub> as the *debug target Exception level*.

### D2.12.2 Rules for setting MDSCR\_EL1.SS to 1

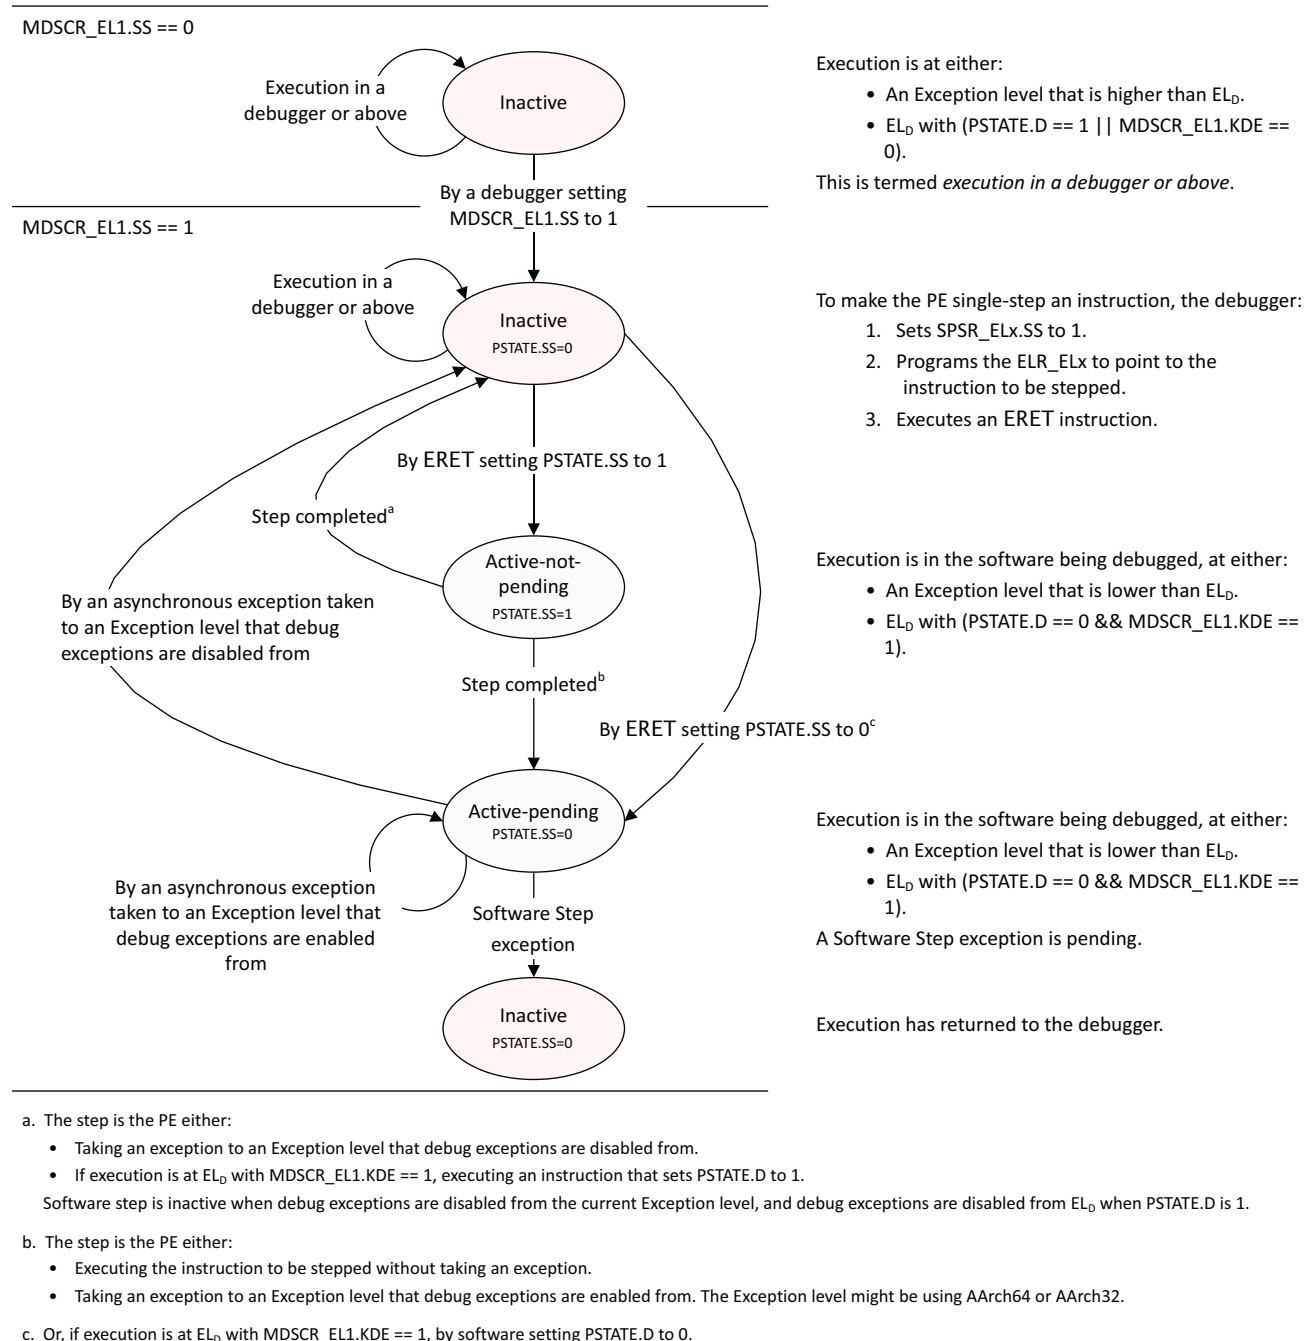

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets MDSCR\_EL1.SS to 1.

The Exception level that hosts the debugger software must be using AArch64.

### D2.12.3 The software step state machine

In Figure D2-4:

- The OS Lock is unlocked and DoubleLockStatus() == FALSE.
- The PE is not in Secure state with MDCR\_EL3.SDD set to 1. That is, the PE is in Non-secure state, or is in Secure state with MDCR\_EL3.SDD set to 0, or the implementation does not include EL3.

**Figure D2-4 Software step state machine**

For a description of when debug exceptions are enabled or disabled from an Exception level, see [Enabling debug exceptions from the current Exception level and Security state on page D2-1913](#).

For more information about how a step is completed, see [Behavior in the active-not-pending state on page D2-1962](#).

The software step states are:

**Inactive** Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:

- [MDSCR\\_EL1.SS](#) is 0.
- $EL_D$  is using AArch32.
- Debug exceptions are disabled from the current Exception level or Security state.

#### Active-not-pending

None of the conditions mentioned in [Inactive](#) are true, therefore software step is active.  
The current instruction is the instruction to be stepped.

#### Active-pending

None of the conditions mentioned in [Inactive](#) are true, therefore software step is active.  
A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not pending state or the active-pending state depends on [PSTATE.SS](#). [Table D2-21](#) shows this.

**Table D2-21 State machine states**

$EL_D$ using:	Debug exception enable status in the current Exception level and Security state	<a href="#">MDSCR_EL1.SS</a>	<a href="#">PSTATE.SS</a>	State machine state
AArch32	X	X	X	Inactive
AArch64	Disabled	X	X	Inactive
AArch64	Enabled	0	X	Inactive
AArch64	Enabled	1	1	Active-not-pending
AArch64	Enabled	1	0	Active-pending

### D2.12.4 Entering the active-not-pending state

Software step can only enter the active-not-pending state from the inactive state.

Software step:

- Enters the active-not-pending state when an ERET instruction writes 1 to [PSTATE.SS](#), by copying from [SPSR\\_ELx.SS](#) when it restores [PSTATE](#).
- Might enter the active-not-pending state on exiting Debug state when [DSPSR\\_EL0.SS](#) or [DSPSR.SS](#) is 1. See [Exiting Debug state on page H2-5471](#).

An ERET instruction only copies 1 from [SPSR\\_ELx.SS](#) to [PSTATE.SS](#) if all of the following are true:

- [MDSCR\\_EL1.SS](#) is 1.
- $EL_D$  is using AArch64.
- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the ERET instruction targets.

Otherwise, ERET instructions set [PSTATE.SS](#) to 0, regardless of the value of [SPSR\\_ELx.SS](#).

[Table D2-22 on page D2-1959](#) shows this. In the table:

**Lock** Means the value of ([OSLSR\\_EL1.OSLK](#) == '1' || DoubleLockStatus()).

**NS** Is [SCR\\_EL3.NS](#).

**SDD** Is [MDCR\\_EL3.SDD](#). See [Disabling debug exceptions from Secure state on page D2-1914](#).

**TDE** Is `MDCR_EL2.TDE`. See *Routing debug exceptions* on page D2-1911.

**Table D2-22 Value an ERET writes to `PSTATE.SS`**

<code>MDSCR_EL1.SS</code>	Lock	NS	SDD	TDE	EL1 is using	EL2 is using	Value an ERET writes to <code>PSTATE.SS</code>
0	X	X	X	X	X	X	0
1	TRUE	X	X	X	X	X	0
	FALSE	0	1	X	X	n/a	0
			0	X	AArch32	n/a	0
			1	0	AArch64	n/a	See <a href="#">Table D2-23 on page D2-1960</a>
					AArch32	X	0
					AArch64	AArch64	See <a href="#">Table D2-23 on page D2-1960</a>
					AArch32	AArch32	0
					X	AArch64	See <a href="#">Table D2-24 on page D2-1961</a>

For:

- `SCR_EL3.NS` == 0 or `MDCR_EL2.TDE` == 0, and EL1 using AArch64, so that `EL_D` is EL1 using AArch64, [Table D2-23 on page D2-1960](#) shows the value an ERET writes to `PSTATE.SS`.
- `SCR_EL3.NS` == 1 and `MDCR_EL2.TDE` == 1 and EL2 using AArch64, so that `EL_D` is EL2 using AArch64, [Table D2-24 on page D2-1961](#) shows the value an ERET writes to `PSTATE.SS`.

In both tables:

**From EL** Means the Exception level at which the PE executes the ERET instruction.

**Target EL** Is the target Exception level of the ERET.

**Note**

If the ERET is an illegal exception return, the target Exception level of the ERET is the current Exception level. See *Illegal return events from AArch64 state* on page D1-1816.

**KDE** Is `MDSCR_EL1.KDE`. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1913.

Table D2-23 Value an ERET writes to **PSTATE.SS** if **EL<sub>D</sub>** is **EL1** using **AArch64**

From EL	Target EL	KDE	<b>PSTATE.D</b>	<b>SPSR_ELx.D</b>	Software step enable status at:		Value an ERET writes to <b>PSTATE.SS</b>
					From EL	Target EL	
EL3	EL3	X	X	X	Disabled	Disabled	0
	EL2	X	X	X	Disabled	Disabled	0
	EL1	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	<b>SPSR_EL3.SS</b>
	EL0	X	X	X	Disabled	Enabled	<b>SPSR_EL3.SS</b>
EL2	EL2	X	X	X	Disabled	Disabled	0
	EL1	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	<b>SPSR_EL2.SS</b>
	EL0	X	X	X	Disabled	Enabled	<b>SPSR_EL2.SS</b>
EL1	EL1	0	X	X	Disabled	Disabled	0
		1	0	X	Enabled <sup>a</sup>	_ <sup>b</sup>	0
			1	1	Disabled	Disabled	0
				0	Disabled	Enabled	<b>SPSR_EL1.SS</b>
	EL0	0	X	X	Disabled	Enabled	<b>SPSR_EL1.SS</b>
		1	0	X	Enabled <sup>a</sup>	Enabled	0
			1	X	Disabled	Enabled	<b>SPSR_EL1.SS</b>

a. Because **MDSCR\_EL1.SS** == 1, it means that the ERET is itself being stepped.

b. Depends on **SPSR\_EL1.D**.

Table D2-24 Value an ERET writes to **PSTATE.SS** if **EL<sub>D</sub>** is **EL2** using **AArch64**

From EL	Target EL	KDE	<b>PSTATE.D</b>	<b>SPSR_ELx.D</b>	Software step enable status at:		Value an ERET writes to <b>PSTATE.SS</b>
					From EL	Target EL	
EL3	EL3	X	X	X	Disabled	Disabled	0
	EL2	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	<b>SPSR_EL3.SS</b>
	EL1	X	X	X	Disabled	Enabled	<b>SPSR_EL3.SS</b>
	EL0	X	X	X	Disabled	Enabled	<b>SPSR_EL3.SS</b>
EL2	EL2	0	X	X	Disabled	Disabled	0
		1	0	X	Enabled <sup>a</sup>	_b	0
			1	1	Disabled	Disabled	0
				0	Disabled	Enabled	<b>SPSR_EL2.SS</b>
	EL1	0	X	X	Disabled	Enabled	<b>SPSR_EL2.SS</b>
		1	0	X	Enabled <sup>a</sup>	Enabled	0
			1	X	Disabled	Enabled	<b>SPSR_EL2.SS</b>
	EL0	0	X	X	Disabled	Enabled	<b>SPSR_EL2.SS</b>
		1	0	X	Enabled <sup>a</sup>	Enabled	0
			1	X	Disabled	Enabled	<b>SPSR_EL2.SS</b>
EL1	EL1	X	X	X	Enabled <sup>a</sup>	Enabled	0
	EL0	X	X	X	Enabled <sup>a</sup>	Enabled	0

a. Because **MDSCR\_EL1.SS** == 1, it means that the ERET is itself being stepped.

b. Depends on **SPSR\_EL2.D**.

———— **Note** ————

No AArch32 instruction can set **PSTATE.SS** to 1.

## D2.12.5 Behavior in the active-not-pending state

In this state, the PE does one of the following:

- Executes the instruction to be stepped and either:
  - Completes it without taking a synchronous exception.
  - Takes a synchronous exception if the instruction generates one.
- Takes an asynchronous exception without executing any instructions.
- Enters Debug state because of a *Halting debug event*.

If the PE executes the instruction without taking any exceptions, then the PE sets `PSTATE.SS` to 0, meaning that after the instruction has been executed:

- If the instruction has disabled debug by setting `PSTATE.D` to 1 then software step advances to the inactive state.
- If the instruction disables software step by a direct write to a System register, for example a write to `MDSCR_EL1.KDE` or `MDSCR_EL1.SS`, then software step might advance to the inactive state. These writes require explicit synchronization to guarantee their effect. See *Synchronization and the software step state machine* on page D2-1968.
- Otherwise, software step advances to the active-pending state. See *Behavior in the active-pending state* on page D2-1964.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

- *If the PE takes an exception to an Exception level that is using AArch64.*
- *If the PE takes an exception to an Exception level that is using AArch32* on page D2-1963.

If the PE enters Debug state because of a Halting debug event, behavior is as described in *Entering Debug state and Software Step* on page H2-5444.

### If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

- Sets `SPSR_ELx.SS` to 0 or 1, depending on the exception. See Table D2-25.
- Sets `PSTATE.SS` to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:
  - Enabled** Software step enters the active-pending state.
  - Disabled** Software step enters the inactive state.
 In either case, on taking the exception, a step is complete.
- Sets `PSTATE.D` to 1.

**Table D2-25 Categorization of exceptions, for setting `SPSR_ELx.SS` to 0 or 1**

Exception description	Exceptions	<code>SPSR_ELx.SS</code>
Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped.	Supervisor Call (SVC) exceptions. Hypervisor Call (HVC) exceptions. Secure Monitor Call (SMC) exceptions.	0
Exceptions whose preferred return address is the address of the instruction to be stepped.	All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped.	1

---

**Note**

---

If an SMC instruction executed at Non-secure EL1 is trapped to EL2 because [HCR\\_EL2.TSC](#) is 1, the exception is a Trap exception, not a Secure Monitor Call exception, and so [SPSR\\_ELx.SS](#) is set to 1, not 0.

---

**If the PE takes an exception to an Exception level that is using AArch32**

This can only happen when all of the following is true:

- EL2 is implemented and is using AArch64, the PE is executing in Non-secure state, and [MDCR\\_EL2.TDE](#) is 1. Because [MDCR\\_EL2.TDE](#) is 1,  $EL_D$  is EL2.
- The exception is taken to Non-secure EL1 using AArch32.

As part of exception entry, the PE sets [PSTATE.SS](#) to 0. This causes software step to enter the active-pending state.

---

**Note**

---

- Software step always enters the active-pending state because the exception is taken to an Exception level that debug exceptions are enabled from, EL1. Debug exceptions are enabled from EL1 because  $EL_D$  is EL2, and debug exceptions are always enabled from Exception levels that are lower than  $EL_D$ .
  - AArch32 SPSRs have no SS bit. Where an [SPSR\\_ELx](#) register architecturally maps to an AArch32 [SPSR\\_<mode>](#) register, [SPSR\\_ELx.SS](#) maps to [SPSR\\_<mode>\[21\]](#).  
[SPSR\\_<mode>\[21\]](#) is always RES0. The PE always sets [SPSR\\_<mode>\[21\]](#) to 0 on taking an exception to an Exception level that is using AArch32.
- 

**Summary of behavior in the active-not-pending state**

[Table D2-26](#) summarizes behavior in the active-not-pending state.

**Table D2-26 Summary of behavior in the active-not-pending state**

Event	Value written to <a href="#">PSTATE.SS</a>	Target Exception level is using:	Details <sup>a</sup>	Value written to <a href="#">SPSR_ELx.SS</a>	Next state
No exception	0	n/a	Disables Software step	n/a	Inactive
			Otherwise	n/a	Active-pending
Exception	0	AArch64	Supervisor Call (SVC) Hypervisor Call (HVC) Secure Monitor Call (SMC)	0	Active-pending or inactive <sup>b</sup>
			Other	1	
		AArch32	All	0 <sup>c</sup>	Active-pending

a. For the *No exception* rows, this column shows the effect of the event.

For the *Exception* rows, this column shows the exception taken.

b. Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See [Figure D2-4 on page D2-1957](#).

c. [SPSR\\_<mode>\[21\]](#) is RES0.

## D2.12.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

- [MDSCR\\_EL1.SS](#) is 1.
- Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

### While software step is in the active-not-pending state

The PE either:

- Executing the instruction to be stepped without taking any exceptions.
- Taking an exception.

### While software step is in the active-pending state

The PE takes an asynchronous exception.

### While software step is in the inactive state

The PE executes either:

- An ERET instruction when [SPSR\\_ELx.SS](#) is 0.
- An instruction that enables debug by setting [PSTATE.D](#) to 0.

### ———— Note ————

If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to Non-secure EL1 when [MDSCR\\_EL2.TDE](#) is 1. Otherwise, debug exceptions are masked by [PSTATE.D](#), therefore they would be disabled from the target Exception level of the exception.

In addition, software step might enter the active-pending state either:

- After a direct write to a System register, for example a write to [MDSCR\\_EL1.KDE](#) or [MDSCR\\_EL1.SS](#). These writes require explicit synchronization to guarantee their effect. See *Synchronization and the software step state machine* on page D2-1968.
- On exiting Debug state when [DSPSR\\_EL0.SS](#) or [DSPSR.SS](#) is 0. See *Exiting Debug state* on page H2-5471.

## D2.12.7 Behavior in the active-pending state

When the PE is in the active-pending state, a Software Step exception is taken before the PE executes an instruction.

The Software Step exception has higher priority than all other types of synchronous exception. However, the prioritization of this exception with respect to any unmasked pending asynchronous exception is not defined by the architecture.

For more information, see the following:

- *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827.
- *Prioritization and recognition of interrupts* on page D1-1841.
- *Architectural requirements for taking asynchronous exceptions* on page G1-4346.

## D2.12.8 Stepping T32 IT instructions

The ARMv8-A architecture permits a combination of an IT instruction and another 16-bit T32 instruction to comprise one 32-bit instruction.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers this combination to be one instruction.
- The PE considers this combination to be two instructions.

In an implementation that supports the ITD control, that can disable some uses of the IT instruction, it is then IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD field. For example:

- The PE might consider this combination to be one instruction, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be two instructions, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be one instruction when the applicable ITD field is 1, and two instructions when it is 0.

The applicable ITD field is one of:

- [SCTLR\\_EL1.ITD](#) if execution is at EL0 using AArch32 when EL1 is using AArch64.
- [SCTLR.ITD](#) if execution is at Non-secure EL0 or EL1 using AArch32.
- [HSCTLR.ITD](#) if execution is at Non-secure EL2 using AArch32.

## D2.12.9 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address on page D2-1967](#).

### Exception syndrome information

On taking a Software Step exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- [ESR\\_EL1](#).
- [ESR\\_EL2](#).

#### ————— **Note** —————

Software Step exceptions cannot be taken to EL3.

[Table D2-27 on page D2-1966](#) shows the information that the PE records.

**Table D2-27 Information recorded in the [ESR\\_ELx](#)**

<b>ESR_ELx field</b>	<b>Information recorded in <a href="#">ESR_EL1</a> or <a href="#">ESR_EL2</a></b>	
<i>Exception Class</i> , EC	The PE sets this to: <ul style="list-style-type: none"> <li>• 0x32, if the exception was taken from a lower Exception level.</li> <li>• 0x33, if the exception was taken from the current Exception level.</li> </ul>	
<i>Instruction Length</i> , IL	The PE sets this to 1.	
<i>Instruction Specific Syndrome</i> , ISS	<b>ISS[24]</b>	<i>Instruction Syndrome Valid</i> (ISV). This indicates whether the EX bit, ISS[6], is valid. The PE sets this to: <ul style="list-style-type: none"> <li><b>0</b> Not valid.</li> <li><b>1</b> Valid.</li> </ul>
	<b>ISS[23:7]</b>	RES0.
	<b>ISS[6]</b>	<i>Exclusive operation</i> (EX). The PE sets this to indicate whether the instruction stepped was a Load-Exclusive instruction: <ul style="list-style-type: none"> <li><b>0</b> The stepped instruction was not a Load-Exclusive instruction.</li> <li><b>1</b> The stepped instruction was a Load-Exclusive instruction.</li> </ul> A debugger can use this information when stepping code that uses Exclusives monitors. See <a href="#">Stepping code that uses Exclusives monitors on page D2-1968</a>
	<b>ISS[5:0]</b>	<i>Instruction Fault Status Code</i> (IFSC). The PE sets this to the code for a debug exception, 0b100010.

When an instruction has been stepped, the PE sets:

- The value of ISS.ISV to 1, to indicate that the EX bit is valid.
- The value of EX to indicate whether the instruction stepped was a Load-Exclusive instruction, using the ISS.EX values shown in [Table D2-27](#).

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, the PE sets both [ESR\\_ELx](#).{ISV, EX} to 0.

———— **Note** ————

An implementation that always sets ISV to 0 and never sets EX is not compliant.

[ESR\\_ELx](#).ISV is UNKNOWN if, in the active-not-pending state, either:

- The instruction stepped was an ERET or an ISB. In these cases, [ESR\\_ELx](#).EX is set to 0.
- [MDCR\\_EL2](#).TDE was set to 1 and either:
  - The instruction to be stepped generated a synchronous exception that was taken to Non-secure EL1. In this case, the instruction to be stepped never completed.
  - The PE took an asynchronous exception to Non-secure EL1 before it could execute the instruction to be stepped. In this case, the instruction to be stepped was never executed.

In both of these cases, [ESR\\_ELx](#).EX is set to the correct value for the instruction.

Table D2-28 shows the permitted scenarios.

**Table D2-28 Values that the PE can record in `ESR_ELx.{ISV, EX}`**

Description	<code>ESR_ELx.ISV</code>	<code>ESR_ELx.EX</code>
Syndrome data is not available because no instruction was stepped.	0	0
Syndrome data is available because an instruction was stepped. The instruction stepped was an instruction other than a Load-Exclusive instruction.	1	0
Syndrome data is available because an instruction was stepped. The instruction stepped was a Load-Exclusive instruction.	1	1
The instruction stepped was an ERET or an ISB.	UNKNOWN	0
The instruction to be stepped generated a synchronous exception that was taken to Non-secure EL1.	UNKNOWN	Set to the correct value for the instruction.
The PE took an asynchronous exception before it could execute the instruction to be stepped.	UNKNOWN	Set to the correct value for the instruction.

`ESR_ELx.EX` is UNKNOWN if the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code test.

#### ———— **Note** ————

A Load-Exclusive instruction is any one of the following:

- In the A64 instruction set, any instruction that has a mnemonic starting with either LDX or LDAX.
- In the A32 and T32 instruction sets, any instruction that has a mnemonic starting with either LDREX or LDAEX.

### Preferred return address

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

## D2.12.10 Additional considerations

This section contains the following:

- *[Behavior when an ERET instruction is an illegal exception return.](#)*
- *[Behavior when the instruction stepped writes a misaligned PC value](#) on page D2-1968.*
- *[Stepping code that uses Exclusives monitors](#) on page D2-1968.*
- *[Synchronization and the software step state machine](#) on page D2-1968.*

### Behavior when an ERET instruction is an illegal exception return

If the conditions for entering the active-not-pending state in [Entering the active-not-pending state](#) on page D2-1958 are met, but the PE executes an ERET instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the ERET, software step can advance from the inactive state to one of the active states. Consider the following case:

1. `MDSCR_EL1.SS` is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and `MDCR_EL2.TDE` is 0, `MDSCR_EL1.KDE` is 1, and `PSTATE.D` is 1.  
`PSTATE.D == 1` is the reason why software step is inactive, because `PSTATE.D == 1` means that debug exceptions are disabled from the current Exception level.
2. The PE executes an ERET instruction.

3. The intended target of the ERET is EL2. This means that the ERET is an illegal exception return because the intended target is higher than the Exception level the ERET it is executed at. In this case, the ERET must target EL1 instead of EL2.  
If `SPSR_EL1.D` is 0, then on the ERET `PSTATE.D` becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether `SPSR_ELx.SS` is 1 or 0:

- If `SPSR_ELx.SS` is 1, software step advances to the active-not-pending state.  
In this case, an Illegal Execution state exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution state exception instead of executing the instruction to be stepped.
- If `SPSR_ELx.SS` is 0, software step advances to the active-pending state.  
In this case, a Software Step exception and an Illegal Execution state exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets `SPSR_ELx.IL` to 1.

---

**Note**

*Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* shows the relative priorities of synchronous exceptions.

---

## Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a PC alignment fault exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

- |                |   |
|----------------|---|
| <b>AArch64</b> | A PC alignment fault exception is generated.  |
| <b>AArch32</b> | The return from the Software Step exception forces the PC to the correct alignment, and no PC alignment fault exception is generated. |

Debugger software must therefore take care when using software step to single-step an indirect branch instruction executed in AArch32 state, that it does not hide a PC alignment fault exception.

## Stepping code that uses Exclusives monitors

The ARMv8-A architecture provides no mechanism for preserving the state of the Exclusives monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive instruction.

Debugger software can use this to detect the state of the Exclusives monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all Exclusives monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see *Exception syndrome information and preferred return address on page D2-1965*.

## Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a System register.
- A direct write to a Special-purpose register.
- A write to an external debug register that affects the routing of debug exceptions.

Because the software step state machine indirectly reads these registers, it is not guaranteed to observe any new values until after a *Context synchronization event* has occurred.

In the time between a write to one of these registers and the next *Context synchronization event*, it is CONSTRAINED UNPREDICTABLE whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a *Context synchronization event*, the state machine must use the state of the PE after the write.

### Example D2-3

1. Software changes `MDSCR_EL1.SS` from 0 to 1 when debug exceptions are enabled.
2. The PE executes some instructions.
3. A *Context synchronization event* occurs.

During step 2, it is CONSTRAINED UNPREDICTABLE whether software step remains in the inactive state, as if `MDSCR_EL1.SS` is 0, or enters the active-pending state because `MDSCR_EL1.SS` is 1. If it is in the:

- Inactive state, then after the *Context synchronization event*, it must enter the active-pending state.
- Active-pending state, the PE might take a Software Step exception before the *Context synchronization event*.

---

#### **Note**

A direct write to a Special-purpose register does not require explicit synchronization.

---

## D2.12.11 Pseudocode description of Software Step exceptions

`SSAdvance()` advances software step from the active-not-pending state to the active-pending state, by setting `PSTATE.SS` to 0. It is called on completing execution of each instruction.

`CheckSoftwareStep()` checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.

`DebugExceptionReturnSS()` returns the value to write to `PSTATE.SS` on an exception return or an exit from Debug state. See *Entering the active-not-pending state* on page D2-1958.

These functions are defined in *Chapter J1 ARMv8 Pseudocode*.

## D2.13 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a *Context synchronization event* has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a *Context synchronization event* has occurred.

For any instructions executed between the time when the change is made and the time when the next *Context synchronization event* occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

### Example D2-4

- 
1. Software changes `MDSCR_ELI.MDE` from 0 to 1.
  2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
  3. A *Context synchronization event* occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

---

### Example D2-5

- 
1. Software unlocks the OS lock.
  2. The PE executes some instructions.
  3. A *Context synchronization event* occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

---

#### Note

- Some register updates are self-synchronizing. Others require an explicit *Context synchronization event*. For more information, see:
    - *Accessing PSTATE fields* on page D1-1792.
    - *Synchronization requirements for AArch64 System registers* on page D7-2191.
    - *Synchronization of changes to the external debug registers* on page H8-5554.
-

# Chapter D3

## The AArch64 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- *About the memory system architecture on page D3-1972.*
- *Address space on page D3-1973.*
- *Mixed-endian support on page D3-1974.*
- *Cache support on page D3-1975.*
- *External aborts on page D3-1997.*
- *Memory barrier instructions on page D3-1999.*
- *Pseudocode description of general memory system instructions on page D3-2000.*

## D3.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see [Memory hierarchy on page B2-98](#).

### D3.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a *Virtual Memory System Architecture* (VMSA). [Chapter D4 The AArch64 Virtual Memory System Architecture](#) describes the AArch64 view of the VMSA.

### D3.1.2 Memory attributes

[Memory types and attributes on page B2-107](#) describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

[Table D3-1](#) shows the memory attributes that are visible at the system level.

**Table D3-1 Memory attribute summary**

Memory type	Shareability	Cacheability
Device <sup>a</sup>	Outer Shareable	Non-cacheable.
Normal	One of: <ul style="list-style-type: none"> <li>Non-shareable.</li> <li>Inner Shareable.</li> <li>Outer Shareable.</li> </ul>	One of <sup>b</sup> : <ul style="list-style-type: none"> <li>Non-cacheable.</li> <li>Write-Through Cacheable.</li> <li>Write-Back Cacheable.</li> </ul>

a. Takes additional attributes, see [Device memory on page B2-111](#).

b. See also [Cacheability, cache allocation hints, and cache transient hints on page D3-1977](#).

For more information on cacheability and shareability see [Shareable Normal memory on page B2-108](#), [Non-shareable Normal memory on page B2-109](#), and [Caches and memory hierarchy on page B2-97](#).

## D3.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *physical address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see [Address size configuration on page D4-2014](#).

### D3.2.1 Instruction address space overflow

When a PE performs a *Simple sequential execution* of instructions, it calculates:

$$(\text{address\_of\_current\_instruction}) + (\text{size\_of\_executed\_instruction})$$

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an instruction overflows 0xFFFF FFFF FFFF, the program counter becomes UNKNOWN.

---

**Note**

---

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

---

Where an instruction accesses a sequential set of bytes that crosses the 0xFFFF\_FFFF\_FFFF boundary when tagged addresses are not used, or the 0xxxFF\_FFFF\_FFFF boundary when tagged addresses are used, then the virtual address accessed for the bytes above this boundary is UNKNOWN. When tagged addresses are used, the value of the tag associated with the address also becomes UNKNOWN.

## D3.3 Mixed-endian support

A control bit, [SCTLR\\_EL1.E0E](#) is provided to allow the endianness of explicit data accesses made while executing at EL0 to be controlled independently of those made while executing at EL1. [Table D3-2](#) shows the endianness of explicit data accesses and translation table walks.

**Table D3-2 Endianness support**

Exception level	Explicit data accesses	Stage 1 translation table walks	Stage 2 translation table walks
EL0	<a href="#">SCTLR_EL1.E0E</a>	<a href="#">SCTLR_EL1.EE</a>	<a href="#">SCTLR_EL2.EE</a>
EL1	<a href="#">SCTLR_EL1.EE</a>	<a href="#">SCTLR_EL1.EE</a>	<a href="#">SCTLR_EL2.EE</a>
EL2	<a href="#">SCTLR_EL2.EE</a>	<a href="#">SCTLR_EL2.EE</a>	N/A
EL3	<a href="#">SCTLR_EL3.EE</a>	<a href="#">SCTLR_EL3.EE</a>	N/A

### Note

[SCTLR\\_EL1.E0E](#) has no effect on the endianness of the [LDTR](#), [LDTRH](#), [LDTRSH](#), and [LDTRSW](#) instructions, or on the endianness of the [STTR](#) and [STTRH](#) instructions, when these are executed at EL1.

AArch64 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - [SCTLR\\_ELx.EE](#) is RW and [SCTLR\\_EL1.E0E](#) is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - [SCTLR\\_ELx](#) is RES0 and [SCTLR\\_EL1.E0E](#) is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - [SCTLR\\_ELx](#) is RES1 and [SCTLR\\_EL1.E0E](#) is RW.
- All Exception levels support only little-endianness:
  - [SCTLR\\_ELx](#) is RES0 and [SCTLR\\_EL1.E0E](#) is RES0.
- All Exception levels support only big-endianness:
  - [SCTLR\\_ELx](#) is RES1 and [SCTLR\\_EL1.E0E](#) is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by [PSTATE.E](#). For exception returns to AArch32 state, [PSTATE.E](#) is copied from [SPSR\\_ELx.E](#). If the target Exception level supports only little-endian accesses, [SPSR\\_ELx.E](#) is RES0. If the target Exception level supports only big-endian accesses, [SPSR\\_ELx.E](#) is RES1. [PSTATE.E](#) is ignored in AArch64 state.

The [BigEndian\(\)](#) function determines whether the current Exception level and Execution state are using big-endian data. This function is defined in [Chapter J1 ARMv8 Pseudocode](#).

For more information about endianness in the ARM architecture see [Endian support on page B2-104](#).

## D3.4 Cache support

This section describes the ARMv8 cache identification and control mechanisms, and the A64 cache maintenance instructions, in the following sections:

- [General behavior of the caches.](#)
- [Cache identification on page D3-1976.](#)
- [Cacheability, cache allocation hints, and cache transient hints on page D3-1977.](#)
- [Enabling and disabling the caching of memory accesses on page D3-1978.](#)
- [Behavior of caches at reset on page D3-1980](#)
- [Non-cacheable accesses and instruction caches on page D3-1981.](#)
- [About cache maintenance in AArch64 state on page D3-1981.](#)
- [A64 Cache maintenance instructions on page D3-1985](#)
- [Data cache zero instruction on page D3-1994.](#)
- [Cache lockdown on page D3-1995.](#)
- [System level caches on page D3-1996.](#)
- [Branch prediction on page D3-1996.](#)

See also [Caches in a VMSAv8-64 implementation on page D4-2133.](#)

### D3.4.1 General behavior of the caches

When a memory location has a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

---

#### **Note**

---

For more information, see [The interaction of cache lockdown with cache maintenance instructions on page D3-1995.](#)

---

- Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.

- It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.
- It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
  - The translation regime at the current Exception level.
  - The translation regime at any higher Exception level.
- For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all masters in its shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the [CTR\\_EL0](#) identifies the Cache Write-back Granule.
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer if it was previously visible to that observer.

———— **Note** ————

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the [SCTLR\\_EL1](#).{I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

## D3.4.2 Cache identification

The ARMv8 cache identification registers describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes the cache maintenance instructions that:

- Affect the entire cache, for example [IC IALLU](#).
- Operate by VA, for example [IC IVAU](#).
- Operate by set/way, for example [DC ISW](#).

The cache identification registers are:

- The Cache Type Register, [CTR\\_EL0](#), that defines:
  - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  - The cache indexing and tagging policy of the Level 1 instruction cache.

———— **Note** ————

It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see [System level caches on page D3-1996](#).

- A single Cache Level ID Register, [CLIDR\\_EL1](#), that defines:
  - The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
  - The *Level of Coherence* (LoC) for the caches. See [Terms used in describing the cache maintenance instructions on page D3-1981](#) for the definition of LoC.

- The *Level of Unification Uniprocessor* (LoUU) for the caches. See [Terms used in describing the cache maintenance instructions on page D3-1981](#) for the definition of LoUU.
- An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.
- A single Cache Size Selection Register, [CSSELR\\_EL1](#), that selects the cache level and cache type of the current Cache Size Identification Register.
- For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, [CCSIDR\\_EL1](#), that defines:
  - Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  - The number of sets, associativity and line length of the cache. See [Terms used in describing the cache maintenance instructions on page D3-1981](#) for a definition of these terms.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.
3. For each cache identified at stage 2:
  - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
    - An instruction cache.
    - A data or unified cache.
  - Read the Cache Size ID Register to find details of the cache.

### D3.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in [Memory types and attributes on page B2-107](#), the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

In ARMv8, Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a *cache transient hint* is supported, see [Transient cacheability hint on page D3-1978](#).

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hit is supported the following cache allocation hints can be assigned:

**For read accesses:** Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

**For write accesses:** Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

---

**Note**

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.
- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.
- For VMSAv8-64 translation table walks, the [TCR\\_ELx](#).{IRGNn, ORGNn} fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

### Transient cacheability hint

In ARMv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

---

**Note**

The architecture does not specify what is meant by a *relatively short period*.

The description of the AArch64 [MAIR\\_EL1](#), [MAIR\\_EL2](#), and [MAIR\\_EL3](#) registers, and the AArch32 [MAIR0](#), [MAIR1](#), [HMAIR0](#), and [HMAIR1](#) registers, includes the assignment of the Transient hint in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

## D3.4.4 Enabling and disabling the caching of memory accesses

In ARMv8, Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

---

**Note**

These Cacheability controls replace the cache enable controls provided in previous versions of the ARM architecture.

The Cacheability control fields and their effects are as follows:

#### For the EL1&0 translation regime

- When the value of [SCTLR\\_EL1.C](#) is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL1&0 stage 1 translation tables are Non-cacheable.
- When the value of [SCTLR\\_EL1.I](#) is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of [HCR\\_EL2.CD](#) is 1:
  - All stage 2 translations for data accesses to Normal memory are Non-cacheable.

- All accesses to the EL1&0 stage 2 translation tables are Non-cacheable.
- When the value of [HCR\\_EL2.ID](#) is 1:
  - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of [HCR\\_EL2.DC](#) is 1, all Non-secure stage 1 translations and all accesses to the Non-secure EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of [SCTLR\\_EL1.{I, C}](#). This applies to translations for both data and instruction accesses.

---

**Note**

- In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D4-2097](#).
- The [SCTLR\\_EL1.{C, I}](#) and [HCR\\_EL2.DC](#) fields have no effect on the EL2, EL2&0, and EL3 translation regimes.
- The [HCR\\_EL2.{ID, CD}](#) fields affect only stage 2 of the Non-secure EL1&0 translation regime.
- In Non-secure state, when EL2 is using AArch64 and EL1 is using AArch32, the [HCR\\_EL2.{ID, CD, DC}](#) controls apply as described here, but the EL1 controls are [SCTLR.{C, I}](#).

---

**For the EL2 translation regime**

- When the value of [SCTLR\\_EL2.C](#) is 0:
  - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
  - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of [SCTLR\\_EL2.I](#) is 0:
  - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

---

**Note**

The [SCTLR\\_EL2.{I, C}](#) fields have no effect on the EL1&0 and EL3 translation regimes.

---

**For the EL2&0 translation regime**

When the value of [SCTLR\\_EL2.C](#) is 1:

- All stage 2 translations for data accesses to Normal memory from EL2, and from EL0 when those accesses are using the EL2&0 translation regime, are Non-cacheable.
- All accesses to the EL2&0 translation tables are Non-cacheable.

**For the EL3 translation regime**

- When the value of [SCTLR\\_EL3.C](#) is 0:
  - All data accesses to Normal memory using the EL3 translation regime are Non-cacheable.
  - All accesses to the EL3 translation tables are Non-cacheable.
- When the value of [SCTLR\\_EL3.I](#) is 0:
  - All instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

---

**Note**

The [SCTLR\\_EL3.{I, C}](#) fields have no effect on the EL1&0, EL2, and EL2&0 translation regimes.

---

In addition:

- For translation regimes other than the Non-secure EL1&0 translation regime, if the value of `SCTLR_ELx.M` is 0, indicating that stage 1 translations are disabled for that translation regime, then:
  - If the value of `SCTLR_ELx.I` is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
  - If the value of `SCTLR_ELx.I` is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.
- For the Non-secure EL1&0 translation regime, if the value of `SCTLR_EL1.M` is 0, indicating that stage 1 translations are disabled for that translation regime, and the value of `HCR_EL2.DC` is 0:
  - If the value of `SCTLR_EL1.I` is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
  - If the value of `SCTLR_EL1.I` is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

The effect of `SCTLR_ELx.C`, `HCR_EL2.DC` and `HCR_EL2.CD` is reflected in the result of the address translation instructions in the PAR when these bits have an effect on the stages of translation being reported in the PAR.

———— **Note** ————

- In conjunction with the requirements in *Non-cacheable accesses and instruction caches on page D3-1981*, the requirements in this section mean the architecturally required effect of `SCTLR_ELx.I` is limited to its effect on caching instruction accesses in unified caches.
- This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in *Mismatched memory attributes on page B2-118* must be followed to manage the corresponding loss of coherency.

### D3.4.5 Behavior of caches at reset

In ARMv8:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.
- The Cacheability control fields described in *Enabling and disabling the caching of memory accesses on page D3-1978* reset to values that force all memory locations to be treated as Non-cacheable.

———— **Note** ————

This applies only to the controls that apply to the Translation regime that is used by the Exception level and Security state entered on reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
  - Provide a mechanism to ensure the correct initialization of the caches.
  - Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

See also [TLB behavior at reset on page D4-2117](#).

### D3.4.6 Non-cacheable accesses and instruction caches

In AArch64 state, instruction accesses to Non-cacheable Normal memory can be held in instruction caches.

Correspondingly, the sequence for ensuring that modifications to instructions are available for execution must include invalidation of the modified locations from the instruction cache, even if the instructions are held in Normal Non-cacheable memory. This includes cases where System register Cacheability control fields force instruction accesses to memory to be Non-cacheable.

Therefore when using self-modified code in non-cacheable space in a uniprocessor system, the following sequence is required:

```
; Enter this code with <Wt> containing the new 32-bit instruction
; to be held at a location pointed to by <Xn> in Normal Non-cacheable memory.
STR <Wt>, [Xn]
DSB ISH; Ensure visibility of the data stored
IC IVAU, [Xn] ; Invalidate instruction cache by VA to PoU
DSB ISH; Ensure completion of the invalidations
ISB ;
```

In a multiprocessor system, the **IC IVAU** is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence, but additional software steps might be required to synchronize the threads with other PEs. This might be necessary so that the PEs executing the modified instructions can execute an ISB after completing the invalidation, and to avoid issues associated with concurrent modification and execution of instruction sequences.

Larger blocks of instructions can be modified using the **IC IALLU** instruction for a uniprocessor system, or a **IC IALLUIS** for a multiprocessor system.

#### ———— Note ————

This section applies even when the Cacheability control fields force instruction accesses to memory in AArch64 state to be Non-cacheable, as described in [Enabling and disabling the caching of memory accesses on page D3-1978](#).

### D3.4.7 About cache maintenance in AArch64 state

The following sections give general information about cache maintenance:

- [Terms used in describing the cache maintenance instructions.](#)
- [The ARMv8 abstraction of the cache hierarchy on page D3-1984.](#)

The following sections describe the A64 cache maintenance instructions:

- [The instruction cache maintenance instruction \(IC\) on page D3-1986.](#)
- [The data cache maintenance instruction \(DC\) on page D3-1987.](#)

#### ———— Note ————

Some descriptions of the cache maintenance instructions refer to the cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the **SCTLR\_EL1**.{I, C} controls.

### Terms used in describing the cache maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instruction scope can be defined:

- By the virtual address of the memory location to be maintained, referred to as operating *by VA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- [Terminology for cache maintenance instructions operating by set/way.](#)
- [Terminology for Clean, Invalidate, and Clean and Invalidate instructions.](#)

---

**Note**

There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see [The effects of disabling a stage of address translation on page D4-2053](#).

---

### **Terminology for cache maintenance instructions operating by set/way**

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

<b>Level</b>	<p>The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the <a href="#">CLIDR_EL1</a>.</p> <p>In the ARM architecture, the lower numbered cache levels are those closest to the PE. See <a href="#">Memory hierarchy on page B2-98</a>.</p>
<b>Set</b>	<p>Each level of a cache is split up into a number of <i>sets</i>. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.</p> <p>In the ARM architecture, sets are numbered from 0.</p>
<b>Way</b>	<p>The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The <i>way</i> number specifies one of these locations.</p> <p>In the ARM architecture, ways are numbered from 0.</p>

---

**Note**

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

---

### **Terminology for Clean, Invalidate, and Clean and Invalidate instructions**

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.
2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

<b>Clean</b>	<p>A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.</p> <p>The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.</p>
--------------	---

**Invalidate** A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

---

**Note**

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

---

### Clean and Invalidate

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- For instructions operating by VA, two conceptual points are defined:

#### Point of Coherency (PoC)

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

---

**Note**

The presence of system caches can affect the determination of the point of coherency as described in [System level caches on page D3-1996](#).

---

#### Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the [CLIDR\\_EL1](#) relate to these conceptual points:

#### LoC, Level of Coherence

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

#### **LoUU, Level of Unification, uniprocessor**

This field defines the last level of data cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is 0x0, this means that no levels of data cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

#### **LoUIS, Level of Unification, Inner Shareable**

In any implementation:

- This field defines the last level of data or unified cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is 0x0, this means that no levels of data or unified cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see [CLIDR\\_EL1, Cache Level ID Register](#) on page D7-2223.

- For instructions operating by VA, an additional conceptual point is defined in ARMv8.2:

#### **Point of Persistence (PoP)**

The point in a memory system, should it exist, at or beyond the Point of Coherency, where a write to memory is maintained when system power is removed, and reliably recovered when power is restored to the affected locations in memory.

Where the Point of Persistence is not supported, a data cache clean to the Point of Persistence behaves as a data cache clean to the Point of Coherency. For more information, see DC CVAP.

Support for the Point of Persistence does not change the definition or behavior of the CLIDR\_EL1 System register.

### **The ARMv8 abstraction of the cache hierarchy**

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- [Cache maintenance instructions that operate by VA.](#)
- [Cache maintenance instructions that operate by set/way](#) on page D3-1985.

#### **Cache maintenance instructions that operate by VA**

The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being one of:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.
- **Performed to the Point of Persistence.**

See [Terms used in describing the cache maintenance instructions](#) on page D3-1981 for definitions of Point of Coherency, Point of Unification, and **Point of Persistence**, and more information about possible meanings of VA.

[A64 Cache maintenance instructions](#) on page D3-1985 lists the VA-based maintenance instructions.

The CTR\_EL0 holds minimum line length values for:

- The instruction caches.

- The data and unified caches.

These values support efficient invalidation of a range of VAs, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the `CTR_EL0` defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

#### Cache maintenance instructions that operate by set/way

[A64 Cache maintenance instructions](#) lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

### D3.4.8 A64 Cache maintenance instructions

The A64 cache maintenance instructions are part of the A64 system instruction class in the register encoding space. For encoding details and other general information on these system instructions, see [System instructions on page C3-158](#), [SYS on page C6-950](#) and [Cache maintenance instructions, and data cache zero on page C5-318](#).

In general, the instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. **The exception to this is the data cache clean operation to the Point of Persistence, introduced in ARMv8.2, which is supported in AArch64 state only.** [Table D3-3](#) shows these system instructions. Instructions that take an argument include Xt in the instruction description.

#### ———— Note —————

In [Table D3-3](#) the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.

**Table D3-3 System instructions for cache maintenance**

System instructions	Instruction	Notes
Instruction cache maintenance instructions, see <a href="#">System instructions on page C3-158</a>		
<a href="#">IC IALLUIS</a>	Invalidate all to Point of Unification, Inner Shareable	EL1 or higher access.
<a href="#">IC IALLU</a>	Invalidate all to Point of Unification	EL1 or higher access.
<a href="#">IC IVAU</a> , Xt	Invalidate by virtual address to Point of Unification	When <code>SCTLR_EL1.UCI == 1</code> , EL0 access. Otherwise, EL1 or higher access.
Data cache maintenance instructions, see <a href="#">System instructions on page C3-158</a>		
<a href="#">DC IVAC</a> , Xt	Invalidate by virtual address to Point of Coherency	EL1 or higher access.
<a href="#">DC ISW</a> , Xt	Invalidate by set/way	EL1 or higher access.
<a href="#">DC CVAC</a> , Xt	Clean by virtual address to Point of Coherency	When <code>SCTLR_EL1.UCI == 1</code> , EL0 access. Otherwise EL1 or higher access.
<a href="#">DC CVAP</a> , Xt	Clean by virtual address to Point of Persistence	When <code>SCTLR_EL1.UCI == 1</code> , EL0 access. Otherwise EL1 or higher access.
<a href="#">DC CSW</a> , Xt	Clean by set/way	EL1 or higher access.

**Table D3-3 System instructions for cache maintenance (continued)**

System instructions	Instruction	Notes
<a href="#">DC CVAU</a> , Xt	Clean by virtual address to Point of Unification	When <a href="#">SCTLR_EL1.UCI</a> == 1, EL0 access. Otherwise EL1 or higher access.
<a href="#">DC CIVAC</a> , Xt	Clean and invalidate by virtual address to Point of Coherency	When <a href="#">SCTLR_EL1.UCI</a> == 1, EL0 access. Otherwise EL1 or higher access.
<a href="#">DC CISW</a> , Xt	Clean and invalidate by set/way	EL1 or higher access.

A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

The following subsections give more information about these instructions:

- [The instruction cache maintenance instruction \(IC\)](#).
- [The data cache maintenance instruction \(DC\) on page D3-1987](#).
- [EL0 accessibility to cache maintenance instructions on page D3-1988](#).
- [General requirements for the scope of maintenance instructions on page D3-1988](#).
- [Effects of instructions that operate by VA to the Point of Coherency on page D3-1988](#).
- [Effects of instructions operate by VA but not to the Point of Coherency on page D3-1989](#).
- [Effects of All and set/way maintenance instructions on page D3-1989](#).
- [Effects of virtualization and security on the cache maintenance instructions on page D3-1990](#).
- [Boundary conditions for cache maintenance instructions on page D3-1991](#).
- [Ordering and completion of data and instruction cache instructions on page D3-1992](#).
- [Performing cache maintenance instructions on page D3-1993](#).

### The instruction cache maintenance instruction (IC)

[System instructions on page C3-158](#) describes the A64 assembly syntax for this instruction.

When an IC instruction requires an address argument this takes the form of a 64-bit register that holds the virtual address argument. No restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current [ASID](#) (*Address Space Identifier*).
- The current Security state.
- Whether the instruction was executed at EL2, or in Non-secure EL1 state.
- For an instruction executed in Non-secure EL1 state, the current [VMID](#) (*Virtual Machine Identifier*).

For an instruction cache maintenance instruction that operates by VA:

- It is IMPLEMENTATION DEFINED whether the instruction can generate a Translation fault or an Access flag fault.
- The instruction cannot generate a Permission fault, except for the Permission fault case described in [Stage 2 fault on a stage 1 translation table walk on page D4-2109](#).

For more information about these possible faults on an instruction that operates by VA see [MMU faults on page D4-2103](#).

See also [EL0 accessibility to cache maintenance instructions on page D3-1988](#) and [Ordering and completion of data and instruction cache instructions on page D3-1992](#).

## The data cache maintenance instruction (DC)

[System instructions on page C3-158](#) describes the A64 assembly syntax for this instruction.

When a DC instruction requires a set/way/level argument this takes the form of a 64-bit register, the upper 32 bits of which are RES0.

When executed at EL1, a **DC ISW** instruction performs a clean and invalidate, meaning it performs the same maintenance as a **DC CISW** instruction, if all of the following apply:

- EL2 is implemented.
- The value of **HCR\_EL2.SWIO** is 1.
- Either EL3 is not implemented, or EL3 is implemented and the value of **SCR\_EL3.NS** is 1

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see [Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-6133](#) or the instruction description.

When a DC instruction requires an address argument this takes the form of a 64-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current **ASID**.
- The current Security state.
- Whether the instruction was executed at EL2, or in Non-secure EL1 state.
- For an instruction executed in Non-secure EL1 state, the current **VMID**.

A data or unified cache maintenance instruction that operates by VA cannot generate a Permission fault except in the following cases:

- **DC IVAC** requires write permission or else a Permission fault is generated.
- The Permission fault described in [Stage 2 fault on a stage 1 translation table walk on page D4-2109](#).

For more information about these possible faults on an instruction that operates by VA see [MMU faults on page D4-2103](#).

When executed at EL1, a **DC IVAC** or **DC ISW** instruction performs a clean and invalidate, meaning a **DC IVAC** instruction performs the same maintenance as a **DC CIVAC** instruction and a **DC ISW** instruction performs the same maintenance as a **DC CISW** instruction, if all of the following apply:

- EL2 is implemented.
- The value of **HCR\_EL2.VM** is 1, meaning EL1&0 stage two address translation is enabled.
- Either EL3 is not implemented, or EL3 is implemented and the value of **SCR\_EL3.NS** is 1

### ————— Note —————

This also applies to the AArch32 cache maintenance instructions **DCIMVAC** and **DCISW**. See [AArch32 data cache maintenance instructions \(DC\\*\) on page G3-4537](#).

Where DC CVAP is supported:

- The operation is ordered in the same way as DC CVAC.
- A **DSB SY** instruction will wait until completion of all previous DC CVAP instructions.

To complete a store to the Point of Persistence where the store might be to Non-cacheable memory, the following sequence should be used:

```
DMB
DC CVAP, Xt
DSB
```

---

**Note**

If caches, that are invisible to the programmer, exist beyond the Point of Coherency but before the Point of Persistence and hold data that is marked as Non-cacheable, the DC CVAP operation causes the non-cacheable locations to be cleaned from those caches.

---

If a memory fault that sets the [FAR](#) for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the [FAR](#) holds the address specified in the register argument of the instruction.

---

**Note**

Despite its mnemonic, [DC ZVA](#) is not a cache maintenance instruction. For more information, see [DC ZVA, Data Cache Zero by VA](#) on page C5-421.

---

See also [EL0 accessibility to cache maintenance instructions](#) and [Ordering and completion of data and instruction cache instructions](#) on page D3-1992.

### EL0 accessibility to cache maintenance instructions

The [SCTLR\\_EL1.UCI](#) bit enables EL0 access for the [DC CVAU](#), [DC CVAC](#), [DC CVAP](#), [DC CIVAC](#), and [IC IVAU](#) instructions. When EL0 use of these instructions is disabled because [SCTLR\\_EL1.UCI](#) == 0, executing one of these instructions at EL0 generates a trap to EL1, that is reported using EC = 0x18.

For these instructions read access permission is required. When the value of [SCTLR\\_EL1.UCI](#) is 1:

- For the [DC CVAU](#), [DC CVAC](#), [DC CVAP](#), and [DC CIVAC](#) instructions, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, a Permission fault is generated.
- For the [IC IVAU](#) instruction, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, it is IMPLEMENTATION DEFINED whether a Permission fault is generated.

Software can read the [CTR\\_EL0](#) to discover the stride needed for cache maintenance instructions. The [SCTLR\\_EL1.UCT](#) bit enables EL0 access to the [CTR\\_EL0](#). When EL0 access to the Cache Type register is disabled, a register access instruction executed at EL0 is trapped to EL1 using EC = 0x18.

### General requirements for the scope of maintenance instructions

The ARMv8 specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in [General behavior of the caches](#) on page D3-1975, [Behavior of caches at reset](#) on page D3-1980, and [Preloading caches](#) on page B2-101.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

---

**Note**

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

---

### Effects of instructions that operate by VA to the Point of Coherency

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

Table D3-4 shows the scope of the Data and unified cache maintenance instructions.

**Table D3-4 PEs affected by cache maintenance instructions to the Point of Coherency**

Shareability	PEs affected	Effective to
Non-shareable	The PE performing the operation	The Point of Coherency of the entire system
Inner Shareable	All PEs in the same Inner Shareable shareability domain as the PE performing the operation	The Point of Coherency of the entire system
Outer Shareable	All PEs in the same Outer Shareable shareability domain as the PE performing the operation	The Point of Coherency of the entire system

### Effects of instructions operate by VA but not to the Point of Coherency

For these instructions, Table D3-5 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

**Table D3-5 PEs affected by cache maintenance instructions to the Point of Unification**

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The point of unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction
Inner Shareable or Outer Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction

#### ———— Note ————

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.

### Effects of All and set/way maintenance instructions

The [IC IALLU](#) and [DC set/way](#) instructions apply only to the caches of the PE that performs the instruction.

The [IC IALLUIS](#) instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

#### ———— Note ————

The possible presence of system caches, as described in [System level caches on page D3-1996](#), means architecture does not guarantee that all levels of the cache can be maintained using set/way instructions.

## Effects of virtualization and security on the cache maintenance instructions

Each Security state has its own physical address (PA) space, therefore cache entries are associated with PA space.

Table D3-6 shows the effects of virtualization and security on the cache maintenance instructions. In the table, the *Specified entries* are entries that the architecture requires the instruction to affect. The rules described in *General behavior of the caches on page D3-1975* mean that an instruction might also affect other entries.

**Table D3-6 Effects of virtualization and security on the maintenance instructions**

Cache maintenance instructions	Security state	Specified entries
Data or unified cache maintenance instructions		
Invalidate, Clean, or Clean and Invalidate by VA: IVAC, CVAC, <b>DC CVAP</b> , CVAU, CIVAC	Both	All lines that hold the PA that, in the current Security state, is mapped to by the combination of all of: <ul style="list-style-type: none"> <li>The specified VA.</li> <li>For an instruction executed at EL1 or EL0, the current <b>ASID</b> if the location is mapped to by a non-global page.</li> <li>For an instruction executed at Non-secure EL1 or Non-secure EL0, the current <b>VMID</b><sup>a</sup>.</li> </ul>
Invalidate, Clean, or Clean and Invalidate by set/way: ISW, CSW, CISW	Non-secure	Line specified by set/way provided that the entry comes from the Non-secure PA space.
	Secure	Line specified by set/way regardless of the PA space that the entry has come from.
Instruction cache maintenance instructions		
Invalidate by VA: IVAU	Both	All lines corresponding to the specified VA <sup>b</sup> in the current translation regime and: <ul style="list-style-type: none"> <li>For an instruction executed at EL1 or EL0, the current <b>ASID</b>.</li> <li>For an instruction executed at Non-secure EL1 or Non-secure EL0, the current <b>VMID</b><sup>a</sup>.</li> </ul>
Invalidate All: IALLU, IALLUIS	Both	For an instruction executed at: <ul style="list-style-type: none"> <li>Non-secure EL1, all instruction cache lines containing entries associated with the current <b>VMID</b><sup>a</sup>.</li> <li>EL2, all instruction cache lines containing Non-secure entries.</li> <li>EL3 or Secure EL1, all instruction cache lines.</li> </ul>

- a. Dependencies on the **VMID** apply even when **HCR\_EL2.VM** is set to 0. The architecture does not define a reset value for **VTTBR\_EL2.VMID**, and therefore, in any implementation that includes EL2, the boot software executed when reset is deasserted must initialize **VTTBR\_EL2.VMID**.
- b. The type of instruction cache used affects the interpretation of the specified entries in this table such that:
- For a PIPT instruction cache, the cache maintenance applies to all entries whose physical address corresponds to the specified address.
  - For a VIPT instruction cache, the cache maintenance applies to entries whose virtual index and physical tag corresponds to the specified address.

For information on types of instruction cache see *Instruction caches on page D4-2133*.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in *The interaction of cache lockdown with cache maintenance instructions on page D3-1995* applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way instructions can, instead, perform a clean and invalidate by set/way.
- The AArch64 Data cache invalidate instructions, **DC IVAC** and **DC ISW**, at EL1 and EL0, and the AArch32 Data cache invalidate instructions **DCIMVAC** and **DCISW**, at EL1, perform a cache clean as well as a cache invalidation if both of the following apply:
  - The value of **HCR.VM** is 1.
  - The instruction is executed in Non-secure state, or EL3 is not implemented.

The means that, in Non-secure state:

- At EL1 using AArch64 or EL0 using AArch64, a **DC IVAC** instruction performs the same maintenance as a **DC CIVAC** instruction, and a **DC ISW** instruction performs the same maintenance as a **DC CISW** instruction.
- At EL1 using AArch32, a **DCIMVAC** instruction performs the same maintenance as a **DCCIMVAC** instruction, and a **DCISW** instruction performs the same maintenance as a **DCCISW** instruction.
- The AArch64 Data cache invalidate by set/way instruction **DC ISW**, at EL1 and EL0, and the AArch32 Data cache invalidate by set/way instruction **DCISW**, at EL1, perform a cache clean as well as a cache invalidation if both of the following apply:
  - The value of **HCR\_EL2.SWIO** is 1.
  - The instruction is executed in Non-secure state, or EL3 is not implemented.

This means that, in Non-secure state:

- At EL1 using AArch64 or EL0 using AArch64, a **DC ISW** instruction performs the same maintenance as a **DC CISW** instruction.
- At EL1 using AArch32, a **DCISW** instruction performs the same maintenance as a **DCCISW** instruction.
- When the value of **HCR\_EL2.FB** is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch64, this applies to the **TLBI VMALLE1**, **TLBI VAE1**, **TLBI ASIDE1**, **TLBI VAAE1**, **TLBI VALE1**, **TLBI VAALE1**, and **IC IALLU** instructions. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction, for example **IC IALLU** performs the invalidation that would be performed by **IC IALLUIS**.

For more information about the cache maintenance instructions, see [About cache maintenance in AArch64 state on page D3-1981](#), [A64 Cache maintenance instructions on page D3-1985](#), and [Chapter D4 The AArch64 Virtual Memory System Architecture](#).

## Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instruction operates on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  - Is Normal memory or Device memory.
  - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

## Ordering and completion of data and instruction cache instructions

All data cache instructions, other than [DC ZVA](#), that specify an address:

- Execute in program order relative to loads or stores that access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by [CTR\\_EL0.DMinLine](#).
- Can execute in any order relative to loads or stores that access any address with the Device memory attribute, or with Normal memory with Inner Non-cacheable attribute unless a DMB or DSB is executed between the instructions.
- Execute in program order relative to other data cache maintenance instructions, other than DC ZVA, that specify an address within the same cache line of minimum size, as indicated by [CTR\\_EL0.DMinLine](#).
- Can execute in any order relative to loads or stores that access an address in a different cache line of minimum size, as indicated by [CTR\\_EL0.DMinLine](#), unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to other data cache maintenance instructions, other than DC ZVA, that specify an address in a different cache line of minimum size, as indicated by [CTR\\_EL0.DMinLine](#), unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

---

### Note

- Data cache ordering rules by address are consistent with physically indexed physically tagged caches. See [Data and unified caches on page D4-2133](#).
- [Data cache zero instruction on page D3-1994](#) describes the ordering and completion rules for Data Cache Zero.

---

All data cache maintenance instructions that do not specify an address:

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that specify an address, other than Data Cache Zero, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to loads or stores unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

All instruction cache instructions can execute in any order relative to other instruction cache instructions, data cache instructions, loads, and stores unless a DSB is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction.

In all cases, where the text in this section refers to a DMB or a DSB, this means a DMB or DSB whose required access type is both loads and stores.

---

### Note

These ordering requirements are extended from the requirements in AArch32 state given:

- [Ordering of cache and branch predictor maintenance instructions on page G3-4543](#).
- [AArch32 instruction cache maintenance instructions \(IC\\*\) on page G3-4536](#).

## Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the [CTR\\_EL0.DMinLine](#) value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the [CTR\\_EL0.IMinLine](#) value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

### Example code for cache maintenance instructions

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

#### ————— Note —————

Since the set/way instructions are performed only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Since any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the line is not affected by set/way based cache maintenance. Therefore, ARM strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

[System level caches on page D3-1996](#) refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency.

```

MRS    X0, CLIDR_EL1
AND    W3, W0, #0x07000000    // Get 2 x Level of Coherence
LSR    W3, W3, #23
CBZ    W3, Finished
MOV    W10, #0                // W10 = 2 x cache level
MOV    W8, #1                 // W8 = constant 0b1
Loop1: ADD    W2, W10, W10, LSR #1 // Calculate 3 x cache level
LSR    W1, W0, W2              // extract 3-bit cache type for this level
AND    W1, W1, #0x7
CMP    W1, #2
B.LT   Skip                   // No data or unified cache at this level
MSR    CSSELR_EL1, X10        // Select this cache level
ISB
MRS    X1, CCSIDR_EL1         // Read CCSIDR
AND    W2, W1, #7              // W2 = log2(linelen)-4
ADD    W2, W2, #4              // W2 = log2(linelen)
UBFX   W4, W1, #3, #10        // W4 = max way number, right aligned
CLZ    W5, W4                  // W5 = 32-log2(ways), bit position of way in DC operand
LSL    W9, W4, W5              // W9 = max way number, aligned to position in DC operand

```

```

        LSL      W16, W8, W5           // W16 = amount to decrement way number per iteration
Loop2:  UBFX     W7, W1, #13, #15      // W7 = max set number, right aligned
        LSL      W7, W7, W2           // W7 = max set number, aligned to position in DC operand
        LSL      W17, W8, W2          // W17 = amount to decrement set number per iteration
Loop3:  ORR      W11, W10, W9          // W11 = combine way number and cache number ...
        ORR      W11, W11, W7         // ... and set number for DC operand
        DC       CSW, X11             // Do data cache clean by set and way
        SUBS     W7, W7, W17          // Decrement set number
        B.GE     Loop3
        SUBS     X9, X9, X16           // Decrement way number
        B.GE     Loop2
Skip:   ADD      W10, W10, #2          // Increment 2 x cache level
        CMP      W3, W10
        DSB                               // Ensure completion of previous cache maintenance instruction
        B.GT     Loop1
Finished:

```

Similar approaches can be used for all cache maintenance instructions.

### D3.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, [DC ZVA](#), writes 0b00 to each of a block of N bytes, aligned in memory to N bytes in size, where the block in memory is identified by the address passed. There are no alignment restrictions on the address supplied. The [DCZID\\_EL0](#) register indicates the block size that is written with byte values of zero.

Software can restrict access to this instruction. See [Configurable instruction enables and disables, and trap controls on page D1-1842](#).

If disabled, the operation at EL0 is trapped to EL1.

The DC ZVA instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See [Exception from a Data abort on page D1-1811](#) for more information about the encoding of [ESR\\_ELx](#) and the associated ISS field.
- If the memory region being zeroed is any type of Device memory, then DC ZVA generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

#### ————— Note —————

The architecture makes no statements about whether or not a [DC ZVA](#) instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.

### D3.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

#### The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, [DC CSW](#).
  - Cache invalidate by set/way, [DC ISW](#).
  - Cache clean and invalidate by set/way, [DC CISW](#).
  - Instruction cache invalidate all, [IC IALLU](#) and [IC IALLUIS](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using DFSC value defined for this purpose. See [Exception from a Data abort on page D1-1811](#).

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, [DC CVAC](#), [DC CVAP](#), and [DC CVAU](#).
- Cache invalidate by virtual address, [DC IVAC](#).
- Cache clean and invalidate by virtual address, [DC CIVAC](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose. See [ESR\\_ELx on page K11-6285](#).

In an implementation that includes EL2, if [HCR\\_EL2.TIDCP](#) is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

---

**Note**

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

---

**Additional cache functions for the implementation of lockdown**

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see [Reserved encodings for IMPLEMENTATION DEFINED registers on page C5-334](#).

### D3.4.11 System level caches

The ARM Architecture defines a *system cache* as a cache that is not described in the PE Cache Identification registers, [CCSIDR\\_EL1](#) and [CLIDR\\_EL1](#), and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by any cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.
2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entirety of such a cache must be performed, as in the case for power management, it must be performed using non-architectural mechanisms.
3. System caches which lie beyond the point of coherency and so are invisible to the software. The management of such caches is outside the scope of the architecture.

### D3.4.12 Branch prediction

ARMv8 does not define any branch predictor maintenance instructions for AArch64 state.

If branch prediction is architecturally visible, cache maintenance must also apply to branch prediction.

## D3.5 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or debug logic. External aborts include parity or ECC errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 memory structure might generate an external abort.

An external abort is one of the following:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see [Exception terminology on page D1-1777](#).

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous external aborts.

VMSAv8-64 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported. Asynchronous aborts are taken as SError interrupt exceptions. See [Asynchronous exception types, routing, masking and priorities on page D1-1834](#).

Synchronous external aborts are reported using the Instruction Abort and Data Abort exceptions. See [Synchronous exception types, routing and priorities on page D1-1826](#).

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running, ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:

- [External abort on an instruction fetch](#).
- [External abort on data read or write](#).
- [Provision for the classification of external aborts](#).
- [Parity or ECC error reporting on page D3-1998](#).

### D3.5.1 External abort on an instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous.

A synchronous external abort on an instruction fetch is taken precisely using the Instruction Abort exception.

An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation the abort is taken using the SError interrupt exception.

### D3.5.2 External abort on data read or write

Externally-generated errors that occur during a data read or write can be either synchronous or asynchronous.

A synchronous external abort on a data read or write is taken precisely using the Data Abort exception.

An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation the abort is taken using the SError interrupt exception.

### D3.5.3 Provision for the classification of external aborts

In AArch64 state, an implementation can use [ESR\\_ELx.EA, ISS\[9\]](#), to provide more information about synchronous external aborts. For more information, see [Exception from an Instruction abort on page D1-1811](#) and [Exception from a Data abort on page D1-1811](#).

For all aborts other than synchronous external aborts reported using the EC values 0x20, 0x21, 0x24, and 0x25, [ESR\\_ELx.EA, ISS\[9\]](#), returns a value of 0.

#### D3.5.4 Parity or ECC error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache system. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see [Use of the ESR\\_EL1, ESR\\_EL2, and ESR\\_EL3 on page D1-1801](#). However, when parity or ECC error reporting is implemented, it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as external aborts.

## D3.6 Memory barrier instructions

[Memory barriers on page B2-92](#) describes the memory barrier instructions. This section describes the system level controls of those instructions.

### D3.6.1 EL2 control of the shareability of data barrier instructions executed at Non-secure EL0 or EL1

In an implementation that includes EL2 and supports shareability limitations on the data barrier instructions, the [HCR\\_EL2.BSU](#) field can modify the required shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. [Table D3-7](#) shows the encoding of this field.

**Table D3-7 EL2 control of shareability of barrier instructions executed at Non-secure EL0 or EL1**

<a href="#">HCR_EL2.BSU</a>	Minimum shareability of barrier instructions
00	No effect, shareability is as specified by the instruction
01	Inner Shareable
10	Outer Shareable
11	Full system

For an instruction executed at EL0 or EL1 in Non-secure state, [Table D3-8](#) shows how the [HCR\\_EL2.BSU](#) is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction.

**Table D3-8 Effect of HCR\_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL0**

Shareability specified by the DMB or DSB argument	<a href="#">HCR_EL2.BSU</a>	Resultant shareability
Full system	Any	Full system
Outer Shareable	00, 01, or 10	Outer Shareable
	11, Full system	Full system
Inner Shareable	00 or 01	Inner Shareable
	10, Outer Shareable	Outer Shareable
	11, Full system	Full system
Non-shareable	00, No effect	Non-shareable
	01, Inner Shareable	Inner Shareable
	10, Outer Shareable	Outer Shareable
	11, Full system	Full system

## D3.7 Pseudocode description of general memory system instructions

This section lists the pseudocode describing general memory operations:

- [Memory data type definitions](#).
- [Basic memory access](#).
- [Aligned memory access](#).
- [Unaligned memory access](#) on page D3-2001.
- [Exclusives monitors operations](#) on page D3-2001.
- [Access permission checking](#) on page D3-2002.
- [Abort exceptions](#) on page D3-2002.
- [Memory barriers](#) on page D3-2002.

### D3.7.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the [AddressDescriptor](#) type.
- Full address, defined by the [FullAddress](#) type.
- Memory attributes, defined by the [MemoryAttributes](#) type.
- Memory type, defined by the [MemType](#) enumeration.
- Device memory type, defined by the [DeviceType](#) enumeration.
- Normal memory attributes, defined by the [MemAttrHints](#) type.
- Cacheability attributes, defined by the [MemAttr\\_NC](#), [MemAttr\\_WT](#), and [MemAttr\\_WB](#) constants.
- Allocation hints, defined by the [MemHint\\_No](#), [MemHint\\_WA](#), [MemHint\\_RA](#), and [MemHint\\_RWA](#) constants.
- Access permissions, defined by the [Permissions](#) type.

These types are defined in [Chapter J1 ARMv8 Pseudocode](#).

### D3.7.2 Basic memory access

The two forms of the `_Mem[]` accessor, non-assignment (memory read) `_Mem[]` and assignment (memory write) `_Mem[]`, are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The functions address the array using `desc.paddress`, that supplies:

- The physical address.
- An NS bit that selects between the Secure and Non-secure parts of the array.

The attributes in `desc.memattrs` are used by the memory system to determine caching and ordering behaviors as described in [Memory types and attributes](#) on page B2-107, [Ordering and observability](#) on page B2-87, and [Atomicity in the ARM architecture](#) on page B2-82.

An additional parameter to the `_Mem[]` accessor defines the access type, for example normal, exclusive, ordered, or streaming, and whether the access is made as part of a translation table walk.

The actual implemented array of memory might be smaller than the permitted  $2^{48}$  bytes **or, in an implementation that includes ARMv8.2-LPA,  $2^{52}$  bytes**. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

`PAMax()` returns the IMPLEMENTATION DEFINED size of the physical address.

### D3.7.3 Aligned memory access

The two `MemSingle[]` accessors, non-assignment (memory read) `AArch64.MemSingle[]` and assignment (memory write) `AArch64.MemSingle[]`, make atomic, little-endian accesses of size bytes. These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

#### D3.7.4 Unaligned memory access

The two `Mem[]` accessors, Non-assignment (memory read) `Mem[]` and Assignment (memory write) `Mem[]`, make accesses of the required type. If an access is not architecturally defined to be atomic, `Mem[]` synthesizes accesses from multiple calls to `AArch64.MemSingle[]`. It also reverses the byte order if the access is big-endian.

The `AArch64.CheckAlignment()` function checks the alignment of memory accesses.

#### D3.7.5 Exclusives monitors operations

The `AArch64.SetExclusiveMonitors()` function sets the Exclusives monitors for a block of bytes, the size of which is determined by `size`, at the virtual address defined by `address`.

The `AArch64.ExclusiveMonitorsPass()` function checks whether the Exclusives monitors are set to include the location of a number of bytes specified by `size`, at the virtual address defined by `address`. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return `FALSE` if the virtual address is not the same as that used in the previous call to `AArch64.SetExclusiveMonitors()`.

The `ExclusiveMonitorsStatus()` function returns 0 if the previous atomic write was to the same physical memory locations selected by `AArch64.ExclusiveMonitorsPass()` and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The `MarkExclusiveGlobal()` procedure takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The procedure records that the PE `processorid` has requested exclusive access covering at least `size` bytes from `address`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The `MarkExclusiveLocal()` procedure takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The procedure records in a local record that PE `processorid` has requested exclusive access to an address covering at least `size` bytes from `address`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

The `IsExclusiveGlobal()` function takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from `address`. It is IMPLEMENTATION DEFINED whether it returns `TRUE` or `FALSE` if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns `FALSE`.

The `IsExclusiveLocal()` function takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked an address range as exclusive access requested that covers at least the `size` bytes from `address`. It is IMPLEMENTATION DEFINED whether this function returns `TRUE` or `FALSE` if the address marked as exclusive access requested does not cover all of `size` bytes from `address`. If no address is marked as exclusive access requested, then this function returns `FALSE`. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress` `address`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of `size` bytes starting from `address` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of `size` bytes starting from `address` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

### D3.7.6 Access permission checking

The function [AArch64.CheckPermission\(\)](#) is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors. It returns the result of the call to [AArch64.NoFault\(\)](#).

These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

The interpretation of access permission is shown in [Memory access control on page D4-2071](#).

### D3.7.7 Abort exceptions

The function [AArch64.Abort\(\)](#) generates either a Data Abort or an Instruction Abort exception by calling [AArch64.DataAbort\(\)](#) or [AArch64.InstructionAbort\(\)](#). It also can generate a debug exception for debug related faults, see [Chapter D2 AArch64 Self-hosted Debug](#).

The function [AArch64.DataAbort\(\)](#) generates a Data Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, [ESR\\_ELx](#). See [Exception from a Data abort on page D1-1811](#). A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, [AArch64.DataAbort\(\)](#) also sets the FAR to the VA of the abort.

The function [AArch64.InstructionAbort\(\)](#) generates an Instruction Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, [ESR\\_ELx](#). See [Exception from an Instruction abort on page D1-1811](#). A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, [AArch64.InstructionAbort\(\)](#) also sets the FAR to the VA of the abort.

The [FaultRecord](#) type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. [Pseudocode description of the MMU faults on page D4-2112](#) provides a number of wrappers to generate FaultRecords.

The function [AArch64.NoFault\(\)](#) returns a null record that indicates no fault. The [IsFault\(\)](#) function tests whether a FaultRecord contains a fault.

### D3.7.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations [MBReqDomain](#) and [MBReqTypes](#).

These enumerations define the required shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures [DataMemoryBarrier](#), [DataSynchronizationBarrier](#), and [InstructionSynchronizationBarrier](#) perform the memory barriers.

# Chapter D4

## The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 *Virtual Memory System Architecture* (VMSAv8-64), the memory system architecture of an ARMv8 implementation that is executing in AArch64 state. It contains the following sections:

- *About the Virtual Memory System Architecture (VMSA)* on page D4-2004.
- *The VMSAv8-64 address translation system* on page D4-2008.
- *VMSAv8-64 translation table format descriptors* on page D4-2060.
- *Memory access control* on page D4-2071.
- *Memory region attributes* on page D4-2090.
- *Virtualization Host Extensions* on page D4-2098.
- *MMU faults* on page D4-2103.
- *Translation Lookaside Buffers (TLBs)* on page D4-2113.
- *TLB maintenance requirements and the TLB maintenance instructions* on page D4-2119.
- *Caches in a VMSAv8-64 implementation* on page D4-2133.

## D4.1 About the Virtual Memory System Architecture (VMSA)

This chapter describes the ARMv8 *Virtual Memory System Architecture* (VMSA), and in particular how it applies to a PE that is executing in AArch64 state. In this state the PE is using VMSAv8-64, as defined in [ARMv8 VMSA naming](#). See [The ARMv8 VMSA when some Exception levels are using AArch32](#) for information about the VMSA in other contexts.

A VMSA provides a *Memory Management Unit* (MMU), that controls address translation, access permissions, and memory attribute determination and checking, for memory accesses made by the PE. The process of address translation maps the *virtual addresses* (VAs) used by the PE onto the *physical addresses* (PAs) of the physical memory system. The mapping of a VA to a PA requires either a single stage of translation, or two sequential stages of translation.

The translations are defined independently for different Exception levels and Security states, as described in [The VMSAv8-64 address translation system on page D4-2008](#).

VMSAv8-64 supports tagging of VAs, as described in [Address tagging in AArch64 state on page D4-2006](#). As that section describes, this address tagging has no effect on the address translation process.

The remainder of this chapter gives a full description of VMSAv8-64 for an implementation that includes all of the Exception levels. [The implemented Exception levels and the resulting translation stages and regimes on page D4-2012](#) describes the differences in the VMSA if some Exception levels are not implemented.

### D4.1.1 ARMv8 VMSA naming

The ARMv8 VMSA naming model reflects the possible stages of address translation, as follows:

- VMSAv8** The overall translation scheme, within which an address translation has one or two stages.
- VMSAv8-32** The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch32.  
VMSAv8-32 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch32.
- VMSAv8-64** The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch64.  
VMSAv8-64 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch64.

### D4.1.2 The ARMv8 VMSA when some Exception levels are using AArch32

As stated at the start of the chapter, this chapter describes VMSAv8-64, the ARMv8 VMSA that applies to an Exception level that is using AArch64. However, when a higher Exception level is using AArch64, and therefore using VMSAv8-64, lower Exception levels can be using AArch32. [Chapter G4 The AArch32 Virtual Memory System Architecture](#) describes VMSAv8-32, meaning it describes:

- The translation stages and translation regimes when EL3 is using AArch32.
- Any stages of address translation that are using VMSAv8-32 when EL3 is using AArch64.

However, a PE can be executing at EL0 using AArch32 when the next higher Exception level is using AArch64, for example when EL0 is using AArch32 and EL1 is using AArch64. When this is the case execution at EL0 uses a VMSAv8-64 translation regime as described in [Constraints on accesses from EL0 when EL0 is using AArch32 on page D4-2010](#).

### D4.1.3 VMSA address types and address spaces

A description of the VMSA refers to the following address types.

———— **Note** ————

These descriptions relate to the VMSAv8 description and therefore give more detail than the generic definitions given in the glossary.

#### Virtual address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

———— **Note** ————

This means that an address held in the PC, LR, SP, or an ELR, is a VA.

In AArch64 state, the VA has a maximum address width of either 48 bits **or, when ARMv8.2-LVA is implemented and the 64KB translation granule is used, 52 bits**. As [About address translation and supported input address ranges on page D4-2011](#) describes, a stage of address translation can support one or two VA ranges:

#### Translation stage with a single VA range

For a translation stage that supports a single VA range, a 48-bit VA width gives a VA range of 0x0000000000000000 to 0x000FFFFFFFFFFFFF.

**If ARMv8.2-LVA is implemented and the 64KB translation granule is used, for a translation regime that supports a single VA range, the 52-bit VA width gives a VA range of 0x0000000000000000 to 0x000FFFFFFFFFFFFF.**

#### Translation stage with two VA ranges

For a translation stage that supports two VA subranges, one at the bottom of the full 64-bit address range, and one at the top, as follows:

- The bottom VA range runs up from address 0x0000000000000000.  
With a maximum VA width of 48 bits this gives a VA range of 0x0000000000000000 to 0x000FFFFFFFFFFFFF.  
**With a maximum VA width of 52 bits this gives a VA range of 0x0000000000000000 to 0x000FFFFFFFFFFFFF.**
- The top VA subrange runs up to address 0xFFFFFFFFFFFFFFFF.  
With a maximum VA width of 48 bits this gives a VA range of 0xFFFF000000000000 to 0xFFFFFFFFFFFFFFFF.  
**With a maximum VA width of 52 bits this gives a VA range of 0xFFFF000000000000 to 0xFFFFFFFFFFFFFFFF.**  
Reducing the VA width for this subrange increases the bottom address of the range.

A 48-bit VA range corresponds to an address space of 256TB. **A 52-bit VA range corresponds to an address space of 4PB.**

Each translation regime that takes a VA as an input address can be configured to support fewer than the maximum number of bits of VA space, see [Address size configuration on page D4-2014](#).

#### Intermediate physical address (IPA)

In a translation regime that provides two stages of address translation, the IPA is:

- The OA from the stage 1 translation.
- The IA for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the [PA](#). Alternatively, the translation regime can be considered as having no concept of IPAs.

For more information about maximum address widths, see [Address size configuration on page D4-2014](#).

### Physical address (PA)

The address of a location in a physical memory map. That is, an output address from the PE to the memory system.

The EL3 and Secure EL1 Exception levels provide independent definitions of the PA spaces for Secure and Non-secure operation. This means they provide two independent address spaces, where:

- A VA accessed in Secure state can be translated to either the Secure or the Non-secure PA space.
- When in Non-secure state, a VA is always mapped to the Non-secure PA space.

For more information about maximum address widths, see [Address size configuration on page D4-2014](#).

## D4.1.4 Address tagging in AArch64 state

In AArch64 state, the ARMv8 architecture supports the tagging of addresses. In these cases the top eight bits of the VA are ignored when determining:

- If the translation system is enabled, whether the address is out of range and therefore causes a Translation fault.
- If the translation system is not enabled, whether the address is out of range and therefore causes an Address size fault.
- Whether the address requires invalidation when performing a TLB invalidation instruction by address.

The use of address tags is controlled as follows:

### For addresses using a stage 1 translation that supports two VA ranges

The value of bit[55] of the VA determines the register bit that controls the use of address tags, as follows:

VA[55]=0	TCR_ELx.TBI0 determines whether address tags are used. If stage 1 translation is enabled, TTBR0_ELx holds the base address of the translation tables used to translate the address.
VA[55]=1	TCR_ELx.TBI1 determines whether address tags are used. If stage 1 translation is enabled, TTBR1_ELx holds the base address of the translation tables used to translate the address.

### For addresses using a stage 1 translation that supports a single VA range

TCR\_ELx.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0\_ELx holds the base address of the translation tables used to translate the address.

### ———— Note ————

The TCR\_ELx.TBI{n} bit determines whether address tags are used regardless of whether the corresponding translation regime is enabled.

An address tag enable bit also has an effect on the PC value in the following cases:

- On taking an exception to the controlled Exception level, regardless of whether this is also the Exception level from which the exception was taken.
- Any branch within the controlled Exception level, unless that branch generates an Illegal exception return.
- On performing an exception return that is not an Illegal exception return to the controlled Exception level, regardless of whether this is also the Exception level from which the exception return was performed.

### ———— Note ————

On an Illegal exception return, bits[63:32] of the PC become UNKNOWN.

- Exiting from debug state to the controlled Exception level.

---

**Note**

---

As an example of what is meant by the *controlled Exception level*, [TCR\\_EL3](#). TBI controls this effect for:

- A branch or procedure return within EL3.
  - Taking an exception to EL3.
  - Performing an exception return or a debug state exit to EL3.
- 

The effect of the controlling TBI $\{n\}$  bit is:

**For a translation regime where the stage 1 translation supports two VA ranges**

If the controlling TBI $n$  bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be a sign-extension of bit[55] of that address.

**For a translation regime where the stage 1 translation supports a single VA range**

If the controlling TBI bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be 0x00.

The [AddrTop\(\)](#) pseudocode function shows the algorithm determining the most significant bit of the [VA](#), and therefore whether the [VA](#) is using tagging. For a translation regime where the stage 1 translation supports two [VA](#) ranges, this pseudocode includes the selection between [TTBR0\\_ELx](#) and [TTBR1\\_ELx](#) described in [Selection between TTBR0\\_ELx and TTBR1\\_ELx when two VA ranges are supported on page D4-2045](#).

---

**Note**

---

The required behavior prevents a tagged address being propagated to the program counter.

---

When address tagging is enabled for an address that causes a Data Abort or a Watchpoint, the address tag is included in the [VA](#) returned in the [FAR](#).

## D4.2 The VMSAv8-64 address translation system

The following subsections describe the VMSAv8-64 address translation system, that maps [VAs](#) to [PAs](#):

- [About the VMSAv8-64 address translation system.](#)
- [Controlling address translation stages on page D4-2012.](#)
- [Memory translation granule size on page D4-2021.](#)
- [Translation tables and the translation process on page D4-2026.](#)
- [Overview of the VMSAv8-64 address translation stages on page D4-2030.](#)
- [The VMSAv8-64 translation table format on page D4-2042.](#)
- [The algorithm for finding the translation table descriptors on page D4-2049.](#)
- [The effects of disabling a stage of address translation on page D4-2053.](#)
- [The implemented Exception levels and the resulting translation stages and regimes on page D4-2012.](#)
- [Pseudocode description of VMSAv8-64 address translation on page D4-2055.](#)
- [Address translation instructions on page D4-2056.](#)

Related to this:

- [VMSAv8-64 translation table format descriptors on page D4-2060](#) describes the translation table entries.
- [Memory region attributes on page D4-2090](#) describes the attributes that are held in the translation table entries, including how different attributes can interact.
- [Translation Lookaside Buffers \(TLBs\) on page D4-2113](#) describes the caching of translation table lookups in TLBs, and the architected instructions for maintaining TLBs.
- [AArch64 Address translation examples on page K6-6180](#) gives detailed descriptions of typical examples of translating a [VA](#) to a final [PA](#), and obtaining the memory attributes of that [PA](#).

### D4.2.1 About the VMSAv8-64 address translation system

The *Memory Management Unit* (MMU) controls address translation, memory access permissions, and memory attribute determination and checking, for memory accesses made by the PE.

The general model of MMU operation is that the MMU takes information about a required memory access, including an *input address* (IA), and either:

- Returns an associated *output address* (OA), and the *memory attributes* for that address.
- Is unable to perform the translation for one of a number of reasons, and therefore causes an exception to be generated. This exception is called an MMU fault. System registers are used to report any MMU faults that occur.

The process of mapping an IA to an OA is an *address translation*, or more precisely a single stage of address translation.

When using a VMSA, a *translation regime* maps a [VA](#) to a [PA](#) using one or two stages of translation, and:

- [The AArch64 translation regimes on page D4-2009](#) defines the translation regimes.
- [VMSA address types and address spaces on page D4-2005](#) give more information about [VAs](#) and [PAs](#).

The *translation granule* specifies the granularity of the mapping from IA to OA. That is, it defines both:

- The *page size* for a stage of address translation, where a page is the smallest block of memory for which an IA to OA mapping can be specified.
- The size of a complete translation table for that stage of address translation.

The MMU is controlled by System registers, that provide independent control of each address translation stage, including a control to disable the stage of address translation. [The effects of disabling a stage of address translation on page D4-2053](#) defines how the MMU handles an access for which a required address translation stage is disabled.

This section describes the address translation system for an implementation that includes all of the Exception levels, and gives a complete description of translations that are controlled by an Exception level that is using AArch64. In addition:

- [The ARMv8 VMSA when some Exception levels are using AArch32 on page D4-2004](#) gives information about the VMSA when some Exception levels are using AArch32.
- [The implemented Exception levels and the resulting translation stages and regimes on page D4-2012](#) describes the effect on the address translation model when some Exception levels are not implemented.

Each enabled stage of address translation uses a set of address translations and associated memory properties held in memory mapped tables called *translation tables*. A single translation table lookup can resolve only a limited number of bits of the IA, and therefore a single address translation can require multiple lookups. These are described as different *levels* of lookup.

Translation table entries can be cached in a *Translation Lookaside Buffer* (TLB).

As well as defining the OA that corresponds to the IA, the translation table entries define the following properties:

- For accesses made from Secure state, whether the access is to the Secure or Non-secure address map.
- Memory access permissions.
- Memory region attributes.

For more information, see [Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-2064](#).

The following subsections give more information:

- [The AArch64 translation regimes](#).
- [About address translation and supported input address ranges on page D4-2011](#).
- [The VMSAv8-64 translation table format on page D4-2011](#).

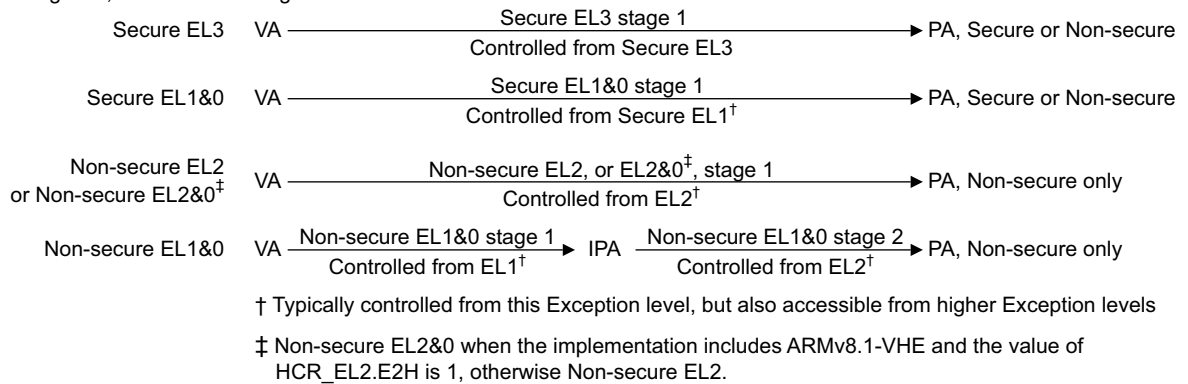

## The AArch64 translation regimes

The architecture defines a number of *translation regimes*, where a translation regime comprises either:

- A single stage of address translation.  
This maps an input VA to an output PA.
- Two, sequential, stages of address translation, where:
  - Stage 1 maps an input VA to an output IPA.
  - Stage 2 maps an input IPA to an output PA.

[Figure D4-1](#) shows these translation stages and translation regimes when EL3 is using AArch64.

Translation regimes, when EL3 is using AArch64

**Figure D4-1 VMSAv8 AArch64 translation regimes, translation stages, and associated controls**

This means that in VMSAv8-64 the set of translation regimes is:

#### The Secure EL3 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

#### The Non-secure EL2 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

In an implementation that:

- Does not include [ARMv8.1-VHE](#) this regime is used for all memory accesses from EL2.
- Includes [ARMv8.1-VHE](#), this regime is used for memory accesses from EL2 only when the value of [HCR\\_EL2.E2H](#) is 0.

#### The Non-secure EL2&0 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports two VA ranges and the use of [ASIDs](#). It is supported only by implementations that include [ARMv8.1-VHE](#), and is used:

- For memory accesses from EL2 when the value of [HCR\\_EL2.E2H](#) is 1.
- For memory accesses from EL0 when the value of [HCR\\_EL2](#).{E2H, TGE} is {1, 1}.

#### The Secure EL1&0 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports two VA ranges and the use of [ASIDs](#).

#### The Non-secure EL1&0 translation regime

If cached in a TLB, a translation table lookup for this regime is associated with the [VMID](#) that identifies the current *virtual machine*. This regime has two stages of lookup:

**Stage 1** Maps VAs to IPAs. This stage supports two VA ranges and the use of [ASIDs](#).

**Stage 2** Maps IPAs to PAs. This stage supports a single IPA range.

An MMU fault might be generated by a particular stage of translation. An MMU fault is described as either a stage 1 MMU fault or a stage 2 MMU fault.

---

#### Note

- In the ARM architecture, a software agent, such as an operating system, that uses or defines stage 1 memory translations, might be unaware of the second stage of translation, and of the distinction between [IPA](#) and [PA](#).
  - A more generalized description of the translation regimes is that a regime always comprises two sequential stages of translation, but in some regimes the stage 2 translation both:
    - Returns an OA that equals the IA. This is called a *flat mapping* of the IA to the OA.
    - Does not change the memory attributes returned by the stage 1 address translation.
- 

#### Constraints on accesses from EL0 when EL0 is using AArch32

ARMv8 permits execution with EL0 using AArch32 when the next higher Exception level is using AArch64. This happens in the following situations:

- EL1 is using AArch64. Execution at EL0 using AArch32 uses the VMSAv8-64 EL1&0 translation regime.
- EL2 is using AArch64 and the *Effective value* of [HCR\\_EL2](#).{E2H, TGE} is {0, 1} or {1, 0}. Execution at EL0 using AArch32 uses the VMSAv8-64 EL1&0 translation regime.
- In an implementation that includes [ARMv8.1-VHE](#), EL2 is using AArch64 and the value of [HCR\\_EL2](#).{E2H, TGE} is {1, 1}. Execution at EL0 using AArch32 uses the VMSAv8-64 EL2&0 translation regime.

In this case, accesses from EL0 using AArch32 are using:

- The stated VMSAv8-64 translation regime, EL1&0 or EL2&0.
- The AArch32 memory model.

In particular, this means the accesses from EL0 are limited to a 32-bit VA range.

## About address translation and supported input address ranges

For a single stage of address translation, a *Translation table base register* (TTBR\_ELx) indicates the start of the first translation table required for a mapping from input address (IA) to output address (OA). For a stage of address translation that supports two VA ranges each VA range is an independent mapping from IA to OA. This means that each implemented translation stage shown in *VMSAv8 AArch64 translation regimes, translation stages, and associated controls* on page D4-2009 requires:

- Two associated sets of translation tables if it supports two IA ranges.
- One associated set of translation tables if it supports a single IA range.

---

### Note

- Stage 2 translations never support two IA ranges. This means that, for the translation stages that support two IA ranges the IA is always a VA.
  - *Example use of the split VA range, and the TTBR0\_ELx and TTBR1\_ELx controls* on page D4-2046 shows how two supported VA ranges might be used.
- 

*Controlling address translation stages* on page D4-2012 summarizes the System registers that control address translation by the MMU, and *Selection between TTBR0\_ELx and TTBR1\_ELx when two VA ranges are supported* on page D4-2045 gives more information about the address translation stages that support two VA ranges.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single IA to OA translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The high bits of the required output address.
- The *attributes* and *access permissions* of the addressed memory.

Translation table entries can be cached in a *Translation Lookaside Buffer*, see *Translation Lookaside Buffers (TLBs)* on page D4-2113.

## The VMSAv8-64 translation table format

Stages of address translation that are controlled by an Exception level that is using AArch64 use the VMSAv8-64 translation table format. This format uses 64-bit descriptor entries in the translation tables.

---

### Note

This format is an extension of the VMSAv8-32 Long-descriptor translation table format originally defined by the ARMv7 Large Physical Address Extension, and extended slightly by ARMv8. VMSAv8-32 also supports a Short-descriptor translation table format. *Chapter G4 The AArch32 Virtual Memory System Architecture* describes both of these formats.

---

The VMSAv8-64 translation table format provides:

- Up to four levels of address lookup.
- A translation granule size of 4KB, 16KB, or 64KB.
- **Input addresses of:**
  - Up to 52 bits if ARMv8.2-LVA is implemented and the 64KB translation granule is used.
  - Otherwise, up to 48 bits.
- **Output addresses of:**
  - Up to 52 bits if ARMv8.2-LPA is implemented and the 64KB translation granule is used.
  - Otherwise, up to 48 bits.

For more information about input address and output address sizes see *Address size configuration* on page D4-2014.

## D4.2.2 The implemented Exception levels and the resulting translation stages and regimes

*About the VMSAv8-64 address translation system on page D4-2008* describes an implementation that includes all Exception levels. *Controlling address translation stages* describes the control of address translation by Exception levels that are using AArch64. This subsection describes how the address translation scheme changes if an implementation does not include all of the Exception levels.

If an implementation does not include EL3, it has only a single Security state, with MMU controls equivalent to the Secure state MMU controls.

If an implementation does not include EL2 then:

- If it also does not include EL3, the MMU provides only a single EL1&0 stage 1 translation regime.
- If it includes EL3, the MMU provides an EL1&0 stage 1 translation regime in each Security state.

*Figure D4-1 on page D4-2009* shows the set of translation regimes for an implementation that implements all of the Exception levels. *Table D4-1* shows how the supported translation stages depend on the implemented Exception levels, and in some cases on the Execution state being used by the highest implemented Exception level.

**Table D4-1 The relation between the implemented translation stages and Exception levels for AArch64**

Translation stage	Requires
Secure EL3 stage 1	EL3 implemented and using AArch64.
Secure EL1&0 stage 1	Either: <ul style="list-style-type: none"> <li>• EL3 implemented and using AArch64.</li> <li>• Only EL1 and EL0 implemented, all operation is in Secure state, and EL1 is using AArch64.</li> </ul>
Non-secure EL2 stage 1 or Non-secure EL2&0 <sup>a</sup> stage 1	EL2 implemented.
Non-secure EL1&0 stage 2	EL2 implemented.
Non-secure EL1&0 stage 1	Any implementation except: <ul style="list-style-type: none"> <li>• Only EL1 and EL0 implemented, with all operation in the Secure state.</li> </ul>

- a. The Non-secure EL2&0 translation regime is supported only if an implementation includes [ARMv8.1-VHE](#). When supported, it is used when the value of [HCR\\_EL2.E2H](#) is 1.

## D4.2.3 Controlling address translation stages

*The implemented Exception levels and the resulting translation stages and regimes* defines the translation regimes and stages. For each supported address translation stage:

- A System register bit enables the stage of address translation.
- A System register bit determines the endianness of the translation table lookups.
- A *Translation Control Register* ([TCR\\_ELx](#)) controls the stage of address translation.
- If a stage of address translation supports two [VA](#) ranges then that stage of translation provides a [TTBR\\_ELx](#) for each [VA](#) range, and the stage of address translation has:
  - A single [TCR\\_ELx](#).
  - A [TTBR\\_ELx](#) for each [VA](#) range. [TTBR0\\_ELx](#) points to the translation tables for the address range that starts at `0x0000000000000000`, and [TTBR1\\_ELx](#) points to the translation tables for the address range that ends at `0xFFFFFFFFFFFFFFFF`.

Otherwise, a single [TTBR\\_ELx](#) holds the address of the translation table that must be used for the first lookup for the stage of address translation.

For address translation stages controlled from AArch64:

- [Table D4-2](#) shows the endianness bit (EE) and the enable bit (M or VM) for each stage of address translation. Each register entry in the table gives the endianness bit followed by the enable bit.

**Table D4-2 Enable and endianness bits for the AArch64 translation stages**

Translation stage	Controlled from	Controlling register
Secure EL3 stage 1	EL3	<a href="#">SCTLR_EL3</a> .{EE, M}
Secure EL1&0 stage 1	Secure EL1	<a href="#">SCTLR_EL1</a> .{EE, M}
Non-secure EL2 stage 1 or Non-secure EL2&0 <sup>a</sup> stage 1	EL2	<a href="#">SCTLR_EL2</a> .{EE, M}
Non-secure EL1&0 stage 2	EL2	<a href="#">SCTLR_EL2</a> .EE, <a href="#">HCR_EL2</a> .VM
Non-secure EL1&0 stage 1	Non-secure EL1	<a href="#">SCTLR_EL1</a> .{EE, M}

- a. The Non-secure EL2&0 translation regime is supported only if an implementation includes [ARMv8.1-VHE](#). When supported, it is used when the value of [HCR\\_EL2](#).E2H is 1.

**Note**

If the [PA](#) of the software that enables or disables a particular stage of address translation differs from its [VA](#), speculative instruction fetching can cause complications. ARM strongly recommends that the [PA](#) and [VA](#) of any software that enables or disables a stage of address translation are identical if that stage of translation controls translations that apply to the software currently being executed.

- [Table D4-3](#) shows the [TCR\\_ELx](#) and [TTBR\\_ELx](#), or [TTBR\\_ELxs](#), for each stage of address translation. In the table, each *Controlling registers* entry gives the [TCR\\_ELx](#) followed by the [TTBR\\_ELx](#) or [TTBR\\_ELxs](#).

**Table D4-3 [TCR\\_ELx](#) and [TTBR\\_ELx](#) for the AArch64 translation stages**

Translation stage	Controlled from	Controlling registers
Secure EL3 stage 1	EL3	<a href="#">TCR_EL3</a> , <a href="#">TTBR0_EL3</a>
Secure EL1&0 stage 1	Secure EL1	<a href="#">TCR_EL1</a> , <a href="#">TTBR0_EL1</a> , <a href="#">TTBR1_EL1</a>
Non-secure EL2 stage 1	EL2	<a href="#">TCR_EL2</a> , <a href="#">TTBR0_EL2</a>
Non-secure EL2&0 <sup>a</sup> stage 1	EL2	<a href="#">TCR_EL2</a> , <a href="#">TTBR0_EL2</a> , <a href="#">TTBR1_EL2</a>
Non-secure EL1&0 stage 2	EL2	<a href="#">VTCR_EL2</a> , <a href="#">VTTBR_EL2</a>
Non-secure EL1&0 stage 1	Non-secure EL1	<a href="#">TCR_EL1</a> , <a href="#">TTBR0_EL1</a> , <a href="#">TTBR1_EL1</a>

- a. The Non-secure EL2&0 translation regime is supported only if an implementation includes [ARMv8.1-VHE](#). When supported, it is used when the value of [HCR\\_EL2](#).E2H is 1.

The following subsections give more information about controlling address translation:

- [System registers relevant to MMU operation on page D4-2014.](#)
- [Address size configuration on page D4-2014.](#)
- [Atomicity of register changes on changing virtual machine on page D4-2020.](#)
- [Use of out-of-context translation regimes on page D4-2020.](#)

## System registers relevant to MMU operation

In AArch64 state, System registers have a suffix, that indicates the lowest Exception level from which they can be accessed. In some general descriptions of MMU control and address translation, this chapter uses a *Common abbreviation* for each of the System registers that affects MMU operation, as Table D4-4 shows. The common abbreviation is used when describing features that apply to multiple translation regimes or stages.

### ————— Note —————

The only translation regime that supports a stage 2 translation is the Non-secure EL1&0 translation regime.

**Table D4-4 Abbreviations for System registers used in this chapter**

Common abbreviation	Translation stage	Exception level		
		EL1	EL2	EL3
HCR_ELx	-	-	HCR_EL2	-
SCTLR_ELx	-	SCTLR_EL1	SCTLR_EL2	SCTLR_EL3
TCR_ELx	Stage 1	TCR_EL1	TCR_EL2	TCR_EL3
	Stage 2	-	VTCR_EL2	-
TTBR_ELx	Stage 1	TTBR0_EL1, TTBR1_EL1	TTBR0_EL2	TTBR0_EL3
	Stage 2	-	VTTBR_EL2	-
TTBR0_ELx	Stage 1	TTBR0_EL1	TTBR0_EL2	TTBR0_EL3
TTBR1_ELx	Stage 1	TTBR1_EL1	TTBR1_EL2 <sup>a</sup>	-

a. Only when both the implementation includes ARMv8.1-VHE and the value of HCR\_EL2.E2H is 1.

## Address size configuration

The following subsections specify the configuration of the PA size and of the input and output address sizes for each of the stages of address translation:

- *Physical address size.*
- *Output address size on page D4-2015.*
- *Input address size on page D4-2016.*
- *Supported IPA size on page D4-2017.*

### Physical address size

The ID\_AA64MMFR0\_EL1.PARange field indicates the implemented PA size, as Table D4-5 shows.

**Table D4-5 Physical address size implementation options**

ID_AA64MMFR0_EL1.PARange	Total PA size	PA address size
0000	4 GB	32 bits, PA[31:0]
0001	64 GB	36 bits, PA[35:0]
0010	1 TB	40 bits, PA[39:0]
0011	4 TB	42 bits, PA[41:0]

**Table D4-5 Physical address size implementation options (continued)**

ID_AA64MMFR0_EL1.PARange	Total PA size	PA address size
0100	16 TB	44 bits, PA[43:0]
0101	256 TB	48 bits, PA[47:0]
0110	4PB	52 bits, PA[51:0] <sup>a</sup>

a. Only when an implementation includes ARMv8.2-LPA and the 64KB translation granule is used, see *Extending addressing above 48 bits* on page D4-2018.

All other PARange values are reserved.

### Output address size

For each enabled stage of address translation, TCR\_ELx.{I}PS must be programmed to maximum output address size for that stage of translation, using the encodings as shown in Table D4-6.

**Table D4-6 Output address size implementation options**

TCR_ELx.{I}PS	Total output size	Output address size
000	4 GB	32 bits, PA[31:0]
001	64 GB	36 bits, PA[35:0]
010	1 TB	40 bits, PA[39:0]
011	4 TB	42 bits, PA[41:0]
100	16 TB	44 bits, PA[43:0]
101	256 TB	48 bits, PA[47:0]
110	4PB	52 bits, PA[51:0] <sup>a</sup>

a. Only when an implementation includes ARMv8.2-LPA and is using the 64KB translation granule, see *Extending addressing above 48 bits* on page D4-2018.

### Note

- The naming of this field is as follows:
  - IPS**
    - In TCR\_EL1.
    - In an implementation that includes ARMv8.1-VHE, in TCR\_EL2 when the value of HCR\_EL2.E2H is 1.
  - PS** Otherwise.
- The {I}PS fields are 3-bit fields, corresponding to the least-significant PARange bits shown in Table D4-5 on page D4-2014.

If {I}PS is programmed to a value larger than the implemented PA size, then the PE behaves as if programmed with the implemented PA size, but software must not rely on this behavior. That is, the output address size is never larger than the implemented PA size. Table D4-5 on page D4-2014 shows the implemented PA size.

The PE checks that the TTBR\_ELx, translation table entries, and the output address for the stage of address translation have the address bits above the output address size set to zero. If this is not the case, an Address size fault is generated for the level and stage of translation that caused the fault. An Address size fault from the TTBR\_ELx is always reported as a level 0 fault. When ARMv8.2-LPA is implemented and a translation granule of 4KB or 16KB is in use, all output addresses are treated as having bits[51:48] set to 0b0000.

If stage 1 translation is disabled and the input address is larger than the implemented [PA](#) size, then a stage 1 level 0 Address size fault is generated.

#### ———— **Note** ————

These faults are reported as level 0 faults even if they occur in a translation stage that does not perform level 0 lookups.

When using two stages of translation:

- If stage 2 translation is disabled and the output address from the stage 1 translation is larger than the implemented [PA](#) size, then a stage 1 Address size fault is generated for the level of the stage 1 translation that generated the output address.
- If stage 2 translation is enabled and the output address from the stage 1 translation does not generate a stage 1 Address Size fault, but is larger than the input address size specified for the stage 2 translation, then a stage 2 Translation fault is generated.

### **Input address size**

For each enabled stage of address translation, the [TCR\\_ELx.TxSZ](#) fields specify the input address size:

#### **For a stage of translation that supports two VA ranges**

The [TCR\\_ELx](#) has two TxSZ fields, corresponding to the two [VA](#) ranges:

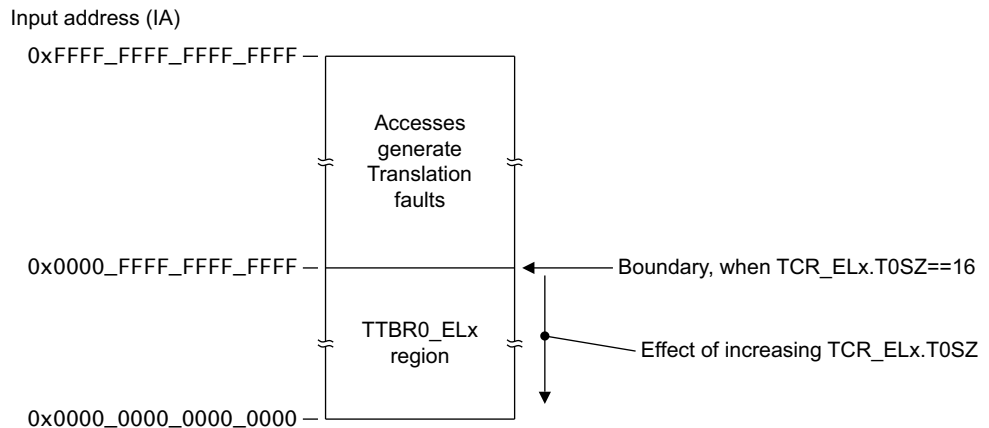

- [TCR\\_ELx.T0SZ](#) specifies the size for the lower [VA](#) range, translated using [TTBR0\\_ELx](#).
- [TCR\\_ELx.T1SZ](#) specifies the size for the upper [VA](#) range, translated using [TTBR1\\_ELx](#).

#### **For a stage of translation that supports a single input address (IA) range**

The [TCR\\_ELx](#) has a single T0SZ field, and IAs are translated using [TTBR0\\_ELx](#).

Attempting to translate an address that is larger than the configured input address size generates a Translation fault. This means:

- For a [TCR\\_ELx](#) with a single T0SZ field and a 48-bit address size, [Figure D4-2](#) shows the input address map:

**Figure D4-2 AArch64 input address map when using a single TTBR and 48-bit input address size**

- For a [TCR\\_ELx](#) with two TxSZ fields, the input address is always a [VA](#), and [Selection between TTBR0\\_ELx and TTBR1\\_ELx when two VA ranges are supported on page D4-2045](#) describes the [VA](#) address map.

For the Non-secure EL1&0 translation regime, when both stages of translation are enabled, if the output address from the stage 1 translation does not generate a stage 1 address size fault, and is larger than the input address size specified by [VTCR\\_EL2.T0SZ](#), then the input address size check for the stage 2 translation generates a Translation fault.

Although software can configure the input address size to be smaller than 48 bits, all implemented AArch64 TTBR\_ELxS must support input address sizes of up to 48 bits, and in an implementation that includes ARMv8.2-LVA, all TTBR\_ELxS must support input address sizes of up to 52 bits.

*Overview of the VMSAv8-64 address translation stages on page D4-2030* gives more information about the relationship between the required input address size, the value of TxSZ, and the required initial lookup level, and how these are affected by the translation granule size. However:

#### For all translation stages

The maximum TxSZ value is 39. If TxSZ is programmed to a value larger than 39 then it is IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field is programmed to 39 for all purposes other than reading back the value of the field.
- Any use of the TxSZ value generates a Level 0 Translation fault for the stage of translation at which TxSZ is used.

#### For a stage 1 translation

The effective minimum value of TxSZ is 16 if [ARMv8.2-LVA](#) is not supported or if the translation granule that is in use is 4KB or 16KB in size. **When ARMv8.2-LVA is supported, for the 64KB translation granule size only, the effective minimum value of TxSZ is 12.**

If TxSZ is programmed to a value smaller than the effective minimum value, and if [ARMv8.2-LVA](#) is not supported, then it IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field were programmed to 16 for all purposes other than reading back the value of the field.
- Any use of the TxSZ value generates a stage 1 level 0 Translation fault.

**If TxSZ is programmed to a value smaller than the effective minimum value when ARMv8.2-LVA is supported, then any use of the TxSZ value generates a stage 1 level 0 Translation fault.**

For more information, see *Extending addressing above 48 bits on page D4-2018*.

#### For a stage 2 translation

*Supported IPA size* defines the effective minimum value of T0SZ, that depends on the supported PA size, and also describes the possible effects of programming T0SZ to a value that is smaller than this effective minimum value.

#### Supported IPA size

For the Non-secure EL1&0 translation regime, the maximum IPA size is the maximum input address size for the second stage of translation, that must be specified by [VTCCR\\_EL2.T0SZ](#), see *Input address size on page D4-2016*. This value is constrained by the implemented PA size that is specified by [ID\\_AA64MMFR0\\_EL1.PARange](#), see *Physical address size on page D4-2014*. This implemented PA size also constrains the maximum value of [VTCCR\\_EL2.SL0](#), that specifies the level of the initial lookup. SL0 also depends on the translation granule, as described in *Overview of the VMSAv8-64 address translation stages on page D4-2030*.

**Table D4-7 PA size implications for the [VTCCR\\_EL2](#).{T0SZ, SL0} fields**

Supported PA size	Effective minimum T0SZ value	Maximum SL0 value		
		4KB granule	16KB granule	64KB granule
32 bits	32 if EL1 is using AArch64 24 if EL1 is using AArch32	1	1	1
36 bits	28 if EL1 is using AArch64 24 if EL1 is using AArch32	1	1	1
40 bits	24	1	1	1

**Table D4-7 PA size implications for the `VTCCR_EL2`.{T0SZ, SL0} fields (continued)**

Supported PA size	Effective minimum T0SZ value	Maximum SL0 value		
		4KB granule	16KB granule	64KB granule
42 bits	22	1	2	1
44 bits	20	2	2	2
48 bits	16	2	2	2
52 bits	12	_a	_a	2

a. Only supported in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule size.

If `VTCCR_EL2`.SL0 is programmed to a value larger than the maximum value shown in Table D4-7 on page D4-2017, or is programmed to a reserved value, then any memory access that uses the second stage of translation generates a stage 2 level 0 Translation fault.

If `VTCCR_EL2`.T0SZ is programmed to a value smaller than the effective minimum value shown in Table D4-7 on page D4-2017, and if ARMv8.2-LPA is not implemented, then the implementation consistently does one of the following:

- Treats the `VTCCR_EL2`.T0SZ field as being programmed to the effective minimum value for all purposes other than reading back the value of the field.
- Treats the `VTCCR_EL2`.T0SZ field as being programmed to the effective minimum value for all purposes other than:
  - Reading back the value of the field.
  - Checking whether the value of `VTCCR_EL2`.T0SZ is consistent with the value of `VTCCR_EL2`.SL0.
- Generates a stage 2 level 0 Translation fault on any memory access that uses the second stage of translation.

If T0SZ is programmed to a value smaller than the effective minimum value when ARMv8.2-LPA is supported, then any use of the T0SZ value generates a stage 2 level 0 Translation fault.

For more information, see *Extending addressing above 48 bits*.

#### ————— Note —————

Programming `VTCCR_EL2`.T0SZ to a value smaller than the effective minimum value shown in Table D4-7 on page D4-2017 can never provide support for a larger address range than the range given by the effective minimum value, because the stage 1 output address will give an Address size fault if it is larger than either:

- The PA size, for a VMSAv8-64 stage 1 translation.
- 40 bits, for a VMSAv8-32 stage 1 translation.

#### **Extending addressing above 48 bits**

ARMv8.2 defines the following options for supporting 52-bit addressing:

**ARMv8.2-LVA** Supports 52-bit VAs. The maximum IPA and PA sizes remain 48-bit.

**ARMv8.2-LPA** Supports 52-bit IPAs and PAs. The maximum VA size remains 48-bit.

ARMv8.2-LPA and ARMv8.2-LVA can be implemented independently of each other.

When using the 64KB translation granule, ARMv8.2-LPA supports Block descriptors in level 1 translation tables. In this case, a block covers a 4TB address range.

In all cases, 52-bit address ranges are supported only when using the 64KB translation granule. Maximum address sizes when using the other translation granules remain 48-bit.

See *Address size configuration* on page D4-2014 for how to configure use of 52-bit VAs when an implementation includes ARMv8.2-LVA.

When using the 64KB translation granule, the 52-bit input address size is supported as follows:

- In an implementation that includes ARMv8.2-LVA, for stage 1 translations the minimum value of TCR\_ELx.TnSZ field is 12.  
If TCR\_ELx.TnSZ is programmed to a value less than 12, any use of the TCR\_ELx.TnSZ bit generates a stage 1 level 0 translation fault.
- In an implementation that includes ARMv8.2-LVA, for a stage 2 translation the effective minimum value of VTCR\_EL2.T0SZ is 12.  
If VTCR\_EL2.T0SZ is programmed to a smaller value than the effective minimum size, then any use of a stage 2 translation generates a stage 2 level 0 translation fault.

Table D4-28 on page D4-2052 shows the translation table descriptor addressing for each level of lookup when using the 64KB translation granule.

In an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule:

- Bits[15:12] of each valid translation table descriptor hold bits[51:48] of the output address, or of the address of the translation table to be used for the initial lookup at the next level of translation. If the implementation does not support 52-bit physical addresses, then non-zero values for these bits generate an Address Size fault.
- For a stage 1 translation, bits[5:2] of TTBR0\_ELx or TTBR1\_ELx holds bits[51:48] of the address of the translation table to be used for the initial lookup of that translation regime.
- For a stage 2 translation, bits[5:2] of VTTBR\_EL2 holds bits[51:48] of the address of the translation table to be used for the initial lookup of the stage 2 translation.
- The minimum alignment of a translation table containing fewer than eight entries is 64 bytes.

———— **Note** ————

This is because, when the OA space is more than 48 bits, TTBR\_ELx[5:2] specifies bits[51:48] of the translation table base address, and a translation table of fewer than eight entries would require one or more bits of TTBR\_ELx[5:2] to be RES0 if the table was aligned to its size.

For more information, see *VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats* on page D4-2060 and *ARMv8 translation table level 3 descriptor formats* on page D4-2063.

The ID\_AA64MMFR2\_EL1.VA field indicates the supported VA size. This field has the value 0x1 if the implementation includes ARMv8.2-LVA.

The ID\_AA64MMFR0\_EL1.PArange field indicates the supported PA and IPA size. This field has the value 0x6 if the implementation supports 52-bit PAs.

In addition to the System registers discussed in this subsection, the ARMv8.2-LPA and ARMv8.2-LVA features affect the following System registers that contain addresses:

- HPFAR\_EL2.
- PAR\_EL1.
- VBAR\_EL1, VBAR\_EL2, VBAR\_EL3.
- DBGVVR<n>\_EL1.
- DBGWVR<n>\_EL1.
- MDRAR\_EL1.
- LOREA\_EL1.
- LORSA\_EL1.

The larger VA, IPA, and PA addresses also affect the following system instructions for TLB maintenance:

- TLBI IPAS2E1.
- TLBI IPAS2E1IS.

- [TLBI IPAS2LE1](#).
- [TLBI IPAS2LE1IS](#).

### Atomicity of register changes on changing virtual machine

From the viewpoint of software executing at Non-secure EL1 or EL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for the Non-secure EL1&0 translation regime. This means that all of the following registers must change atomically:

- The registers associated with the stage 1 translations:
  - [MAIR\\_EL1](#) and [AMAIR\\_EL1](#).
  - [TTBR0\\_EL1](#), [TTBR1\\_EL1](#), [TCR\\_EL1](#), and [CONTEXTIDR\\_EL1](#).
  - [SCTLR\\_EL1](#).
- The registers associated with the stage 2 translations:
  - [VTTBR\\_EL2](#) and [VTCR\\_EL2](#).
  - [SCTLR\\_EL2](#).

---

#### Note

Only some bits of [SCTLR\\_EL1](#) affect the stage 1 translation, and only some bits of [SCTLR\\_EL2](#) affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the Non-secure EL1&0 translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are *out of context* when they are updated, and no synchronization precautions are required.

Similar considerations apply when [ARMv8.1-VHE](#) is implemented.

### Use of out-of-context translation regimes

The architecture requires that:

- When executing at EL3, EL2, or Secure EL1, the PE must not use the registers associated with the Non-secure EL1&0 translation regime for speculative memory accesses.
- When executing at EL3 or Secure EL1, the PE must not use the registers associated with the EL2, or EL2&0 translation regime for speculative memory accesses.
- When executing at EL3, EL2, or Non-secure EL1, the PE must not use the registers associated with the Secure EL1&0 translation regime for speculative memory accesses.

When entering an Exception level, on completion of a DSB instruction, no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered will be observed by any observers, to the extent that those accesses are required to be observed as determined by the shareability and cacheability of those translation table entries.

---

#### Note

- This does not require that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.
- This requirement does not imply that, on taking an exception to a higher Exception level, any translation table walks started before the exception was taken will be completed by the time the higher Exception level is entered, and therefore memory accesses required for such a translation table walk might, in effect, be performed speculatively. However, the execution of a DSB on entry to the higher Exception level ensures that these accesses are complete.

## D4.2.4 Memory translation granule size

The memory translation granule size defines both:

- The maximum size of a single translation table.
- The memory *page* size. That is, the granularity of a translation table lookup.

VMSAv8-64 supports translation granule sizes of 4KB, 16KB, and 64KB. Support for each granule size is optional, and is indicated as shown in [Table D4-8](#):

**Table D4-8 Identifying supported granule sizes**

Granule size	Support indicated by:		Values
	Field		
4KB	ID_AA64MMFR0_EL1.TGRAN4	0b0000	4KB granule size supported.
		0b1111	4KB granule size not supported.
16KB	ID_AA64MMFR0_EL1.TGRAN16	0b0000	16KB granule size not supported.
		0b0001	16KB granule size supported.
64KB	ID_AA64MMFR0_EL1.TGRAN64	0b0000	64KB granule size supported.
		0b1111	64KB granule size not supported.

In VMSAv8-64, each address translation stage is configured, independently, to use one of the supported granule sizes.

### ———— Note ————

- Using a larger granule size can reduce the maximum required number of levels of address lookup because:
  - The increased translation table size means the translation table holds more entries. This means a single lookup can resolve more bits of the input address.
  - The increased page size means more of the least-significant address bits are required to address a page. These address bits are flat mapped from the input address to the output address, and therefore do not require translation.
- ARM recommends that memory-mapped peripherals are separated by an integer multiple of the largest granule size supported by the operating system or hypervisor, to allow each peripheral to be managed independently.

[Table D4-9](#) summarizes the effects of the different granule sizes.

**Table D4-9 Effect of granule size on a stage of address translation**

Property	4KB granule	16KB granule	64KB granule	Notes
Maximum number of entries in a translation table	512	2048 (2K)	8192 (8K)	-
Address bits resolved in one level of lookup	9	11	13	$2^9=512$ , $2^{11}=2K$ , $2^{13}=8K$
Page size	4KB	16KB	64KB	-
Page address range	VA[11:0]= PA[11:0]	VA[13:0]= PA[13:0]	VA[15:0]= PA[15:0]	$2^{12}=4K$ , $2^{14}=16K$ , $2^{16}=64K$

## How the granule size affects the address translation process

As Table D4-9 on page D4-2021 shows, the translation granule determines the number of address bits:

- Required to address a memory page.
- That can be resolved in a single translation table lookup.

This means the translation granule determines how the *input address* (IA) is resolved to an *output address* (OA) by the translation process.

Because a single translation table lookup can resolve only a limited number of address bits, the IA to OA resolution requires multiple *levels* of lookup.

Considering the resolution of an IA range of 48 bits, with a translation granule size of  $2^n$  bytes:

- The least-significant  $n$  bits of the IA address the memory page. This means  $OA[(n-1):0] = IA[(n-1):0]$ .
- The remaining  $(48-n)$  bits of the IA,  $IA[47:n]$ , must be resolved by the address translation.
- A translation table descriptor is 8 bytes. Therefore:
  - A complete translation table holds  $2^{(n-3)}$  descriptors.
  - A single level of translation can resolve a maximum of  $(n-3)$  bits of address.

Consider the translation process, working back from the final level of lookup, that resolves the least significant of the address bits that require translation. Because the translation needs to resolve  $IA[47:n]$  and a level of lookup can resolve  $(n-3)$  bits of address:

- The final level of lookup resolves  $IA[(2n-4):n]$ .
- The previous level of lookup resolves  $IA[(3n-7):(2n-3)]$ .

However, the level of lookup that resolves the most significant bits of the IA might not require a full-sized translation table. Therefore, in general, for a 48-bit IA the address bits resolved in a level of lookup are:

$IA[\text{Min}(47, ((m-3)(n-3)+2n-4)):(n+(x-3)(n-3))]$ , where:

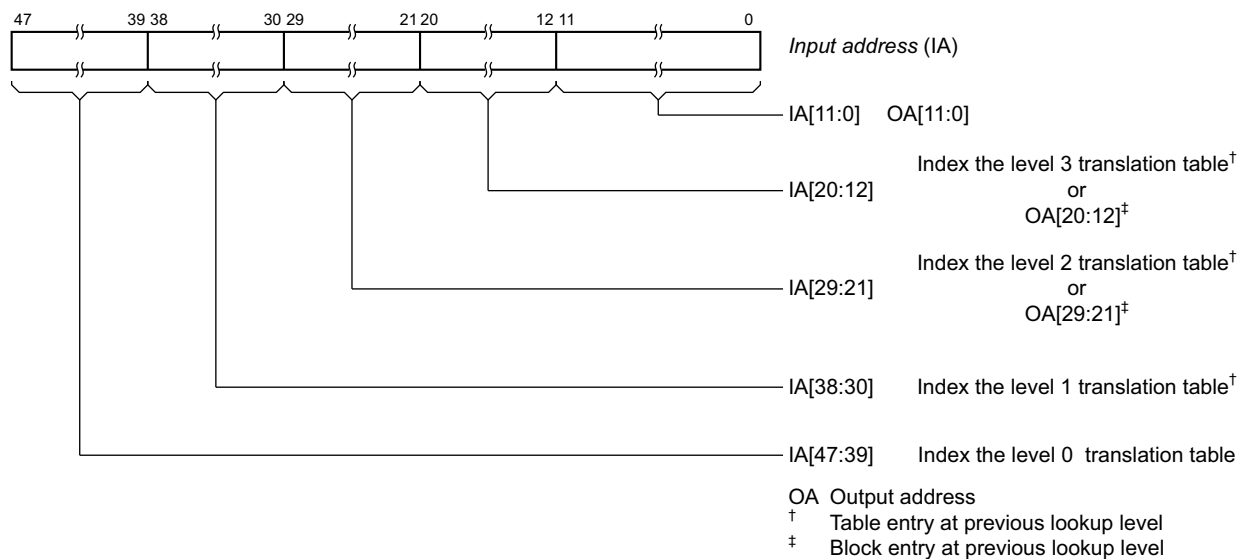

**Min( $a$ ,  $b$ )** Is a function that returns the minimum of  $a$  and  $b$ .

**$m$**  Indicates the level of lookup. This is defined so that the level that resolves the least significant bit of the translated IA bits is level 3.

The following diagrams show this model, for each of the permitted granule sizes.

Figure D4-3 shows how a 48-bit IA is resolved when using the 4KB translation granule.

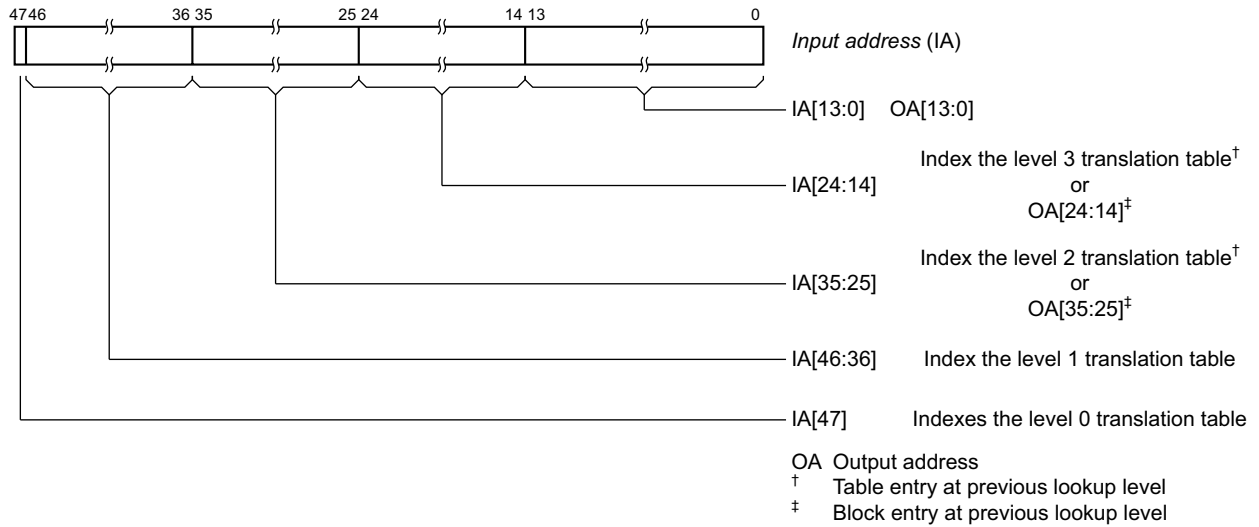

Using the 4KB translation granule

**Figure D4-3** How a 48-bit IA is resolved when using the 4KB translation granule

Figure D4-4 shows how a 48-bit IA is resolved when using the 16KB translation granule.

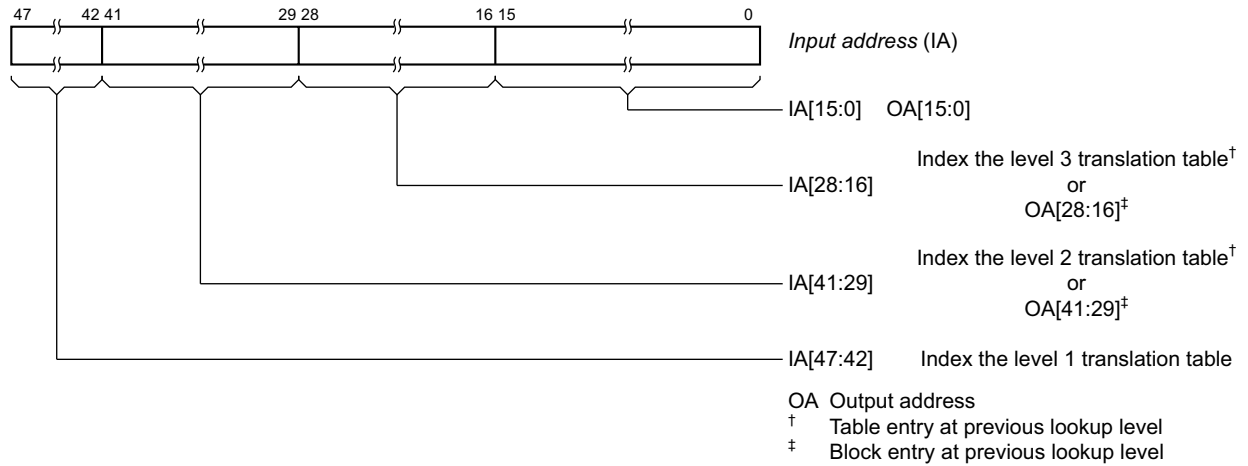

Using the 16KB translation granule

**Figure D4-4 How a 48-bit IA is resolved when using the 16KB translation granule**

Figure D4-5 shows how a 48-bit IA is resolved when using the 64KB translation granule.

Using the 64KB translation granule

**Figure D4-5 How a 48-bit IA is resolved when using the 64KB translation granule**

In an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule:

- The IA range that can be addressed by the level 1 lookup is IA[51:42].
- The level 1 lookup can directly address a block of memory, returning OA[51:42].

———— **Note** ————

The increased IA range means the size of the indexed level 1 translation table is increased.

Later sections of this chapter give more information about the translation process, and explain the terminology used in these figures.

## Effect of granule size on translation table addressing and indexing

Table D4-10 shows the effect of the translation granule size on the addressing and indexing of the `TTBR_ELx`, and on the input address range that must be resolved.

**Table D4-10 The effect of translation granule size on the translation tables**

Granule size	Translation table		Translation resolves <sup>a</sup>	Notes
	Addressed by	Indexed by <sup>b</sup>		
4KB	<code>TTBR_ELx[47:12]</code>	<code>IA[(x + 8):x]</code>	<code>IA[47:12]</code>	One level of lookup resolves up to <sup>c</sup> 9 bits of IA
16KB	<code>TTBR_ELx[47:14]</code>	<code>IA[(x + 10):x]</code>	<code>IA[47:14]</code>	One level of lookup resolves up to <sup>c</sup> 11 bits of IA
64KB	<code>TTBR_ELx[47:16]</code> <sup>d</sup> <code>TTBR_ELx[5:2, 47:16]</code>	<code>IA[(x + 12):x]</code>	<code>IA[47:16]</code> <sup>d</sup> <code>IA[51:16]</code>	One level of lookup resolves up to <sup>c</sup> 13 bits of IA

a. When translating a maximum-sized input address, and accessing a page of memory.

b. Where the value of  $x$  depends on the lookup level, see Table D4-11.

c. Depending on the IA size, the initial lookup might resolve fewer bits of the IA.

d. For the 64KB granule entries in the *Addressed by* and *Translation resolves* columns, the second entry applies to an implementation that includes ARMv8.2-LVA and has selected an IA space larger than 47 bits, see *Extending addressing above 48 bits* on page D4-2018. The first entry applies otherwise.

Table D4-11 shows the IA bits resolved at each level of lookup, and how these correspond to the possible values of  $x$  in Table D4-10.

**Table D4-11 IA bits resolved at different levels of lookup**

Lookup level	4KB granule size	16KB granule size	64KB granule size
Zero	<code>IA[47:39]</code> , $x = 39$	<code>IA[47<sup>a</sup>]</code> , $x = 47$	– <sup>b</sup>
First	<code>IA[38:30]</code> , $x = 30$	<code>IA[46:36]</code> , $x = 36$	<code>IA[47<sup>a</sup>:42]</code> , $x = 42$ <sup>c</sup> <code>IA[51<sup>a</sup>:42]</code> , $x = 42$
Second	<code>IA[29:21]</code> , $x = 21$	<code>IA[35:25]</code> , $x = 25$	<code>IA[41:29]</code> , $x = 29$
Third	<code>IA[20:12]</code> , $x = 12$	<code>IA[24:14]</code> , $x = 14$	<code>IA[28:16]</code> , $x = 16$

a. Smaller value than indicated in Table D4-10, as explained in this section.

b. Level 0 lookup not possible with 64KB granule size

c. The second entry applies to an implementation that includes ARMv8.2-LVA and has selected an IA space larger than 47 bits, see *Extending addressing above 48 bits* on page D4-2018. The first entry applies otherwise.

Table D4-10 on page D4-2024 refers to accessing a complete translation table, of 4KB, 16KB, or 64KB. However, the ARMv8 translation system supports the following possible variations from the information in Table D4-10 on page D4-2024:

#### Reduced IA width

Depending on the configuration and implementation choices, the required input address width for the initial level of lookup might be smaller than the number of address bits that can be resolved at that level. This means that, for this initial level of lookup:

- The translation table size is reduced. For each 1 bit reduction in the input address size the size of the translation table is halved.

#### Note

- This has no effect on the translation table size for subsequent levels of lookup, for which the lookups always use full-sized translation tables.
- For a stage 2 translation, it might be possible to start the translation at a lower level, see [Concatenated translation tables](#).

- More low-order `TTBR_ELx` bits are needed to hold the translation table base address.

Example D4-1 shows how this applies to translating a 35-bit input address range using the 4KB granule.

#### Example D4-1 Effect of an IA width of 35 bits when using the 4KB granule size

With a 4KB granule size, a single level of lookup can resolve up to 9 bits of IA. If an implementation has a 35-bit input address range, `IA[34:0]`, Table D4-11 on page D4-2024 shows that lookup must start at level 1, and that the initial lookup must resolve `IA[34:30]`, meaning it resolves 5 bits of address: This 4-bit reduction in the required resolution means:

- The translation table size is divided by  $2^4$ , giving a size of 256B.
- The `TTBR_ELx` requires 4 more bits for the translation table base address, which becomes `TTBR_ELx[47:8]`.

When using the 64KB translation granule to translate the maximum IA size of 48 bits, Table D4-11 on page D4-2024 shows that a level 1 lookup must resolve only `IA[47:42]`. This is 6 bits of address, compared to the 13 bits that can be resolved at a single level of lookup. This 7-bit reduction in the required resolution means:

- The translation table size is divided by  $2^7$ , giving a size of 512B.
- The `TTBR_ELx` requires 7 more bits for the translation table base address, which becomes `TTBR_ELx[47:9]`.

#### Concatenated translation tables

For stage 2 address translations, for the initial lookup, up to 16 translation tables can be concatenated. This means additional IA bits can be resolved at that lookup level. The block of concatenated translation tables must be aligned to the size of the block of translation tables.

This means that each additional IA bit resolved:

- Doubles the number of translation tables required. Resolving an additional  $n$  bits requires  $2^n$  concatenated translation tables at the initial lookup level.
- Reduces by 1 bit the width of the translation table base address held in the `TTBR_ELx`.

This means that, for the initial lookup of a stage 2 translation table, the IA ranges shown in Table D4-11 on page D4-2024 can be extended by up to 4 bits. Example D4-2 on page D4-2026 shows how concatenation can be used to resolve a 40-bit IA when using the 4KB translation granule.

### Example D4-2 Concatenating translation tables to resolve a 40-bit IA range, with the 4K granule

Table D4-11 on page D4-2024 shows that, when using the 4KB translation granule, a level 1 lookup can resolve a 39-bit IA, with the first lookup resolving IA[38:30]. For a stage 2 translation, to extend the IA width to 40 bits and resolve IA[39:30] with the first lookup:

- Two translation tables are concatenated, giving a total size of 8KB.
- The `TTBR_ELx` requires 1 fewer bit for the translation table base address, which becomes `TTBR_ELx[47:13]`.

For more information, see *Use of concatenated translation tables for the initial stage 2 lookup* on page D4-2047.

In all cases, the translation table, or block of concatenated translation tables, must be aligned to the actual size of the table or block of concatenated tables.

The translation table base address held in the `TTBR_ELx` is defined in the OA map for that stage of address translation. The information given in this section assumes this stage of translation has the maximum OA size, meaning the translation table base address is:

- `TTBR_ELx[47:12]` if using the 4KB translation granule.
- `TTBR_ELx[47:14]` if using the 16KB translation granule.
- `TTBR_ELx[47:16]` if using the 64KB translation granule with an OA of 48 bits.
- In an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule, OA[51:16], where:
  - `TTBR_ELx[5:2]` holds OA[51:48].
  - `TTBR_ELx[47:16]` holds OA[47:16].

If the OA address is smaller than 48 bits then the upper bits of this field must be written as zero. For example, for a 40-bit OA range:

- If using the 4KB translation granule:
  - `TTBR_ELx[47:40]` must be set to zero.
  - `TTBR_ELx[39:12]` holds the translation table base address.
- If using the 16KB translation granule:
  - `TTBR_ELx[47:40]` must be set to zero.
  - `TTBR_ELx[39:14]` holds the translation table base address.
- If using the 64KB translation granule:
  - `TTBR_ELx[47:40]` must be set to zero.
  - `TTBR_ELx[39:16]` holds the translation table base address.

In all cases, if `TTBR_ELx[47:40]` is not zero, any attempt to access the translation table generates an Address size fault.

## D4.2.5 Translation tables and the translation process

The following subsections describe general properties of the translation tables and translation table walks, that are largely independent of the translation table format:

- *Translation table walks* on page D4-2027.
- *Ordering of memory accesses from translation table walks* on page D4-2029.
- *Security state of translation table lookups* on page D4-2029.
- *Control of translation table walks* on page D4-2029.

See also *Selection between `TTBR0_ELx` and `TTBR1_ELx` when two VA ranges are supported* on page D4-2045.

## Translation table walks

A *translation table walk* comprises one or more *translation table lookups*. The translation table walk is the set of lookups that are required to translate the VA to the PA. For the Non-secure EL1&0 translation regime, this set includes lookups for both the stage 1 translation and the stage 2 translation, but *translation table walk* can also be used to refer to either:

- The set of lookups required for the stage 1 translation, that translates the VA to the IPA. This is the *stage 1 translation table walk*.
- The set of lookups required for the stage 2 translation, that translates the IPA to the PA. This is the *stage 2 translation table walk*.

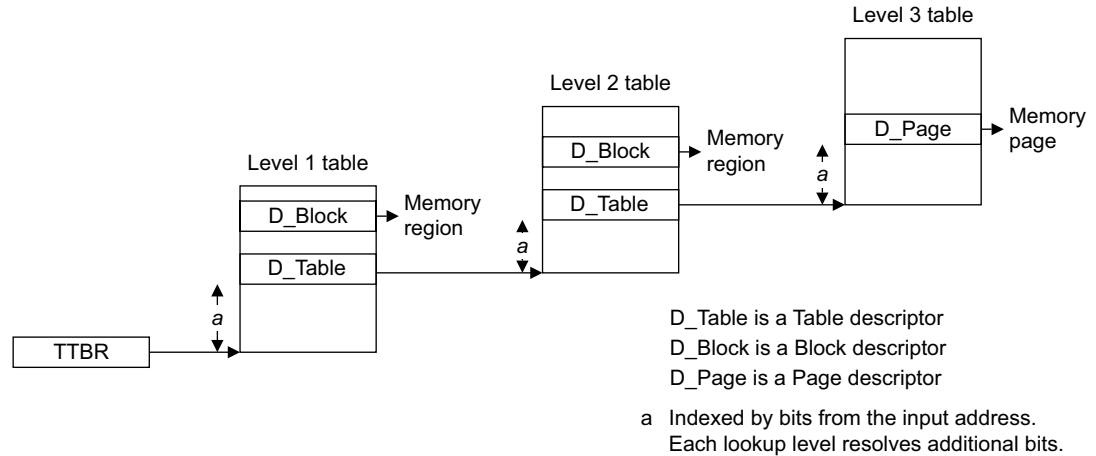

The information returned by a successful translation table walk is:

- The required PA. If the access is from Secure state this includes identifying whether the access is to the Secure PA space or the Non-secure PA space, see *Security state of translation table lookups on page D4-2029*.
- The memory attributes for the target memory region, as described in *Memory types and attributes on page B2-107*. For more information about how the translation table descriptors specify these attributes see *Memory region attributes on page D4-2090*.
- The access permissions for the target memory regions. For more information about how the translation table descriptors specify these permissions see *Memory access control on page D4-2071*.

The translation table walk starts with a read of the translation table for the initial lookup. The TTBR\_ELx for the stage of translation holds the base address of this table. Each translation table lookup returns a descriptor, that indicates one of the following:

- The entry is the final entry of the walk. In this case, the entry contains the OA, and the permissions and attributes for the access.
- An additional level of lookup is required. In this case, the entry contains the translation table base address for that lookup. In addition:
  - The descriptor provides hierarchical attributes that are applied to the final translation, see *Hierarchical control of Secure or Non-secure memory accesses on page D4-2070* and *Hierarchical control of data access permissions on page D4-2074*.
  - If the translation is in a Secure translation regime, the descriptor indicates whether that base address is in the Secure or Non-secure address space, unless a hierarchical control at a previous level of lookup has indicated that it must be in the Non-secure address space.
- The descriptor is invalid. In this case, the memory access generates a Translation fault.

Figure D4-6 on page D4-2028 gives a generalized view of a single stage of address translation where three levels of lookup are required.

**Figure D4-6 Generalized view of a stage of address translation**

A translation table lookup from VMSAv8-64 performs a single-copy atomic 64-bit access to the translation table entry. This means the translation table entry is treated as a 64-bit object for the purpose of endianness.

[SCTLR\\_ELx.EE](#) determines the endianness of the translation table lookups.

#### Note

##### Dynamically changing translation table endianness

Because any change to an [SCTLR\\_ELx.EE](#) bit requires synchronization before it is visible to subsequent operations, ARM strongly recommends that any EE bit is changed only when either:

- Executing at an Exception level that does not use the translation tables affected by the EE bit being changed.
- Executing with address translation disabled for any stage of translation affected by the EE bit being changed.

Address translation stages are disabled by setting an [SCTLR\\_ELx.M](#) bit or the [HCR\\_EL2.VM](#) bit to 0. See the appropriate register description for more information.

The appropriate [TTBR\\_ELx](#) holds the output address of the base of the translation table used for the initial lookup, and:

- For all address translation stages other than Non-secure EL1&0 stage 1 translations, the output address held in the [TTBR\\_ELx](#), and any translation table base address returned by a translation table descriptor, is the [PA](#) of the base of the translation table.
- For Non-secure EL1&0 stage 1 translations, the output address held in the [TTBR\\_ELx](#), and any translation table base address returned by a translation table descriptor, is the [IPA](#) of the base of the translation table. This means that if stage 2 address translation is enabled, each of these OAs is subject to second stage translation.

#### Note

TLB caching can be used to minimize the number of translation table lookups that must be performed. For the Non-secure EL1&0 translation regime, because each stage 1 OA generated during a translation table walk is subject to a stage 2 translation, if the caching of translation table entries is ineffective, a [VA](#) to [PA](#) address translation with two stages of translation can give rise to multiple translation table lookups. The number of lookups required is given by the following equation:

$$(S1+1)*(S2+1) - 1$$

Where, for this translation regime, S1 is the number of levels of lookup required for a stage 1 translation, and S2 is the number of levels of lookup required for a stage 2 translation.

The [TTBR\\_ELx](#) also determines the memory cacheability and shareability attributes that apply, for the corresponding stage of translation, to all translation table lookups generated by that stage of translation.

The Normal memory type is the memory type defined for a translation table lookup for a stage of translation.

#### ————— **Note** —————

- In a two stage translation regime, a translation table lookup from stage 1, that has the Normal memory type defined at stage 1 by this rule, can still be given the Device memory type as part of the stage 2 translation of that address. ARM strongly recommends against such a remapping of the memory type, and the architecture includes a trap of this behavior to EL2. For more information, see [Stage 2 fault on a stage 1 translation table walk on page D4-2109](#).
- The rules about mismatched attributes given in [Mismatched memory attributes on page B2-118](#) apply to the relationship between translation table walks and explicit memory accesses to the translation tables in the same way that they apply to the relationship between different explicit memory accesses to the same location. For this reason, ARM strongly recommends that the attributes that the [TCR\\_ELx](#) applies to the translation tables are the same as the attributes that are applied for explicit accesses to the memory that holds the translation tables.

For more information see [Overview of the VMSAv8-64 address translation stages on page D4-2030](#).

See also [Selection between TTBR0\\_ELx and TTBR1\\_ELx when two VA ranges are supported on page D4-2045](#).

### Ordering of memory accesses from translation table walks

A translation table walk is considered to be a separate observer, and:

- A write to the translation tables can be observed by that separate observer at any time after the execution of the instruction that performed that write, but is only guaranteed to be observable after the execution of a DSB instruction by the PE that executed the instruction that performed that write to the translation tables.
- Any writes to the translation tables are not seen by any explicit memory access generated by a load or store that occurs in program order before the instruction that performs the write to the translation tables.

### Security state of translation table lookups

For a Non-secure translation regime, all translation table lookups are performed to Non-secure output addresses.

For a Secure translation regimes, the initial translation table lookup is performed to a Secure output address.

If the translation table descriptor returned as a result of that initial lookup points to a second translation table, then the NSTable bit in that descriptor determines whether that translation table lookup is made to Secure or to Non-secure output addresses.

This applies for all subsequent translation table lookups as part of that translation table walk, with the additional rule that any translation table descriptor that is returned from Non-secure memory is treated as if the NSTable bit in that descriptor indicates that the subsequent translation table lookup is to Non-secure memory.

### Control of translation table walks

For a stage 1 translation that supports two VA ranges the [TCR\\_ELx](#).{EPD0, EPD1} bits determine whether the translation tables for the stage are valid. EPD0 indicates whether the table that [TTBR0\\_ELx](#) points to is valid, and EPD1 indicates whether the table that [TTBR1\\_ELx](#) points to is valid. The effect of these bits is:

- EPD<sub>n</sub> == 0**    The translation table is valid, and can be used for a translation table lookup.
- EPD<sub>n</sub> == 1**    If a TLB miss occurs based on [TTBR\\_ELx](#), a Translation fault is returned, and no translation table walk is performed. The fault is reported as a level 0 fault.

## D4.2.6 Overview of the VMSAv8-64 address translation stages

As shown in [Memory translation granule size on page D4-2021](#), the granule size determines significant aspects of the address translation process. [Effect of granule size on translation table addressing and indexing on page D4-2024](#) shows, for each granule size:

- How the required input address range determines the required initial lookup levels.
- For stage 2 translations, the possible effect described in [Concatenated translation tables on page D4-2025](#).
- The `TTBR_ELx` addressing and indexing for the initial lookup.

The following subsections summarize the multiple levels of lookup that can be required for a single stage of address translation that might require the maximum number of lookups:

- [Overview of VMSAv8-64 address translation using the 4KB translation granule.](#)
- [Overview of VMSAv8-64 address translation using the 16KB translation granule on page D4-2034.](#)
- [Overview of VMSAv8-64 address translation using the 64KB translation granule on page D4-2038.](#)

### Overview of VMSAv8-64 address translation using the 4KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

#### Overview of stage 1 translations, 4KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding `TCR_ELx.TnSZ` field. When using the 4KB translation granule, [Table D4-12](#) shows this requirement.

**Table D4-12 `TCR_ELx.TnSZ` values and IA ranges, 4K granule with no concatenation of tables**

Initial lookup level	TnSZ values for and input address ranges <sup>a</sup> for starting at this level			
	TnSZ <sub>min</sub>	IA <sub>max</sub>	TnSZ <sub>max</sub>	IA <sub>min</sub>
0	16	IA[47:12]	24	IA[39:12]
1	25	IA[38:12]	33	IA[30:12]
2	34	IA[29:12]	39	IA[24:12]

a. The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.

These configuration options are also permitted for stage 2 translations.

#### **Note**

- When using the 4KB translation granule, the initial lookup cannot be at level 3.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, `IA[11:0] = OA[11:0]` for all translations.

Figure D4-7 shows the stage 1 address translation, for an address translation using the 4KB granule with an input address size greater than 39 bits.

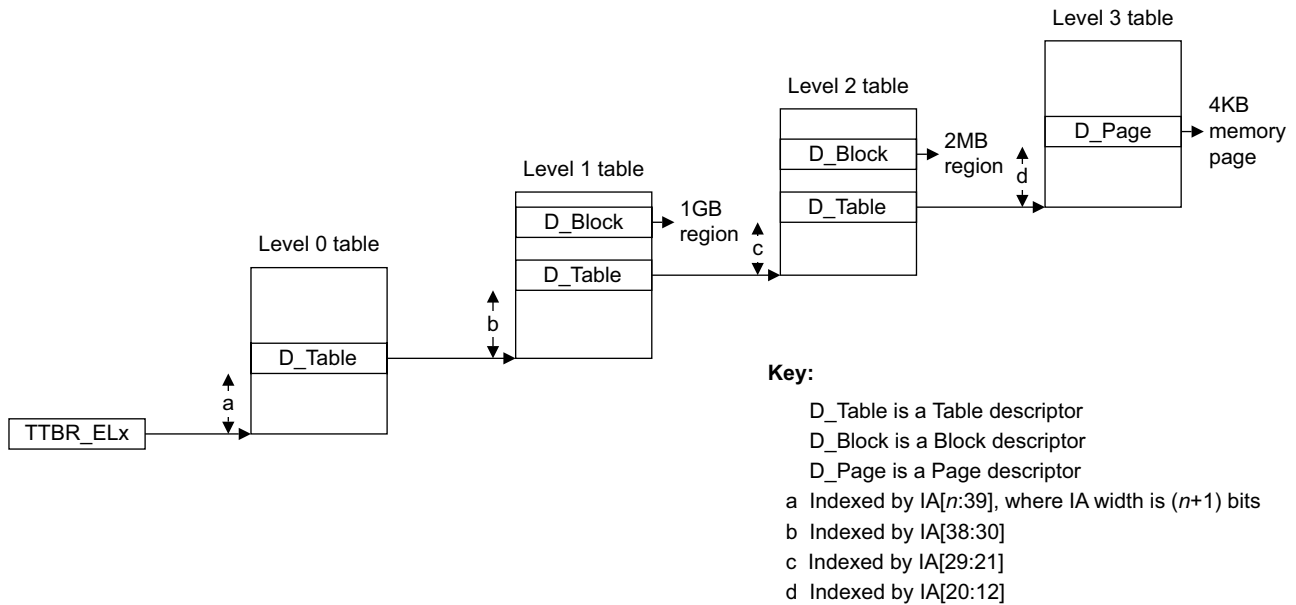

Figure D4-7 General view of VMSAv8-64 stage 1 address translation, 4KB granule

#### Overview of stage 2 translations, 4KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see [Use of concatenated translation tables for the initial stage 2 lookup on page D4-2047](#).

When using the 4KB translation granule, [Table D4-13](#) shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-13 **VTCTR\_EL2.T0SZ** values and IA ranges, 4K granule with possible concatenation of translation tables

Tables <sup>a</sup>	1		2		4		8		16	
Initial lookup level	T0SZ values and input address ranges <sup>b</sup> for starting at this level									
	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
0	16-24	IA[47:12]- IA[39:12]	-	-	-	-	-	-	-	-
1	25-33	IA[38:12]- IA[30:12]	24	IA[39:12]	23	IA[40:12]	22	IA[41:12]	21	IA[42:12]
2	34-39	IA[29:12]- IA[24:12]	33	IA[30:12]	32	IA[31:12]	31	IA[32:12]	30	IA[33:12]

a. Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, also shown in [Table D4-12 on page D4-2030](#).

b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the *Note* that follows.

---

**Note**

---

- When using the 4KB translation granule, the initial lookup cannot be at level 3.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 4KB translation granule, tables cannot be concatenated at level 0.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

---

In addition, [VTCR\\_EL2.SL0](#) indicates the required initial lookup level, as [Table D4-14](#) shows.

**Table D4-14 [VTCR\\_EL2.SL0](#) values, 4KB granule**

Initial lookup level	<a href="#">VTCR_EL2.SL0</a>
0	0b10
1	0b01
2	0b00

The [VTCR\\_EL2.SL0](#) value 0b11 is reserved.

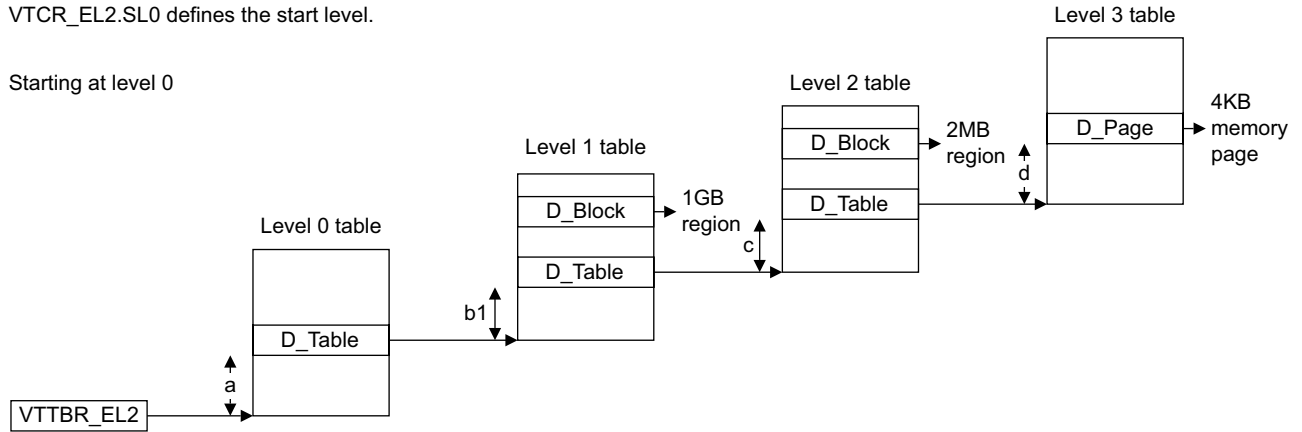

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted [VTCR\\_EL2.{T0SZ, SL0}](#) values. [Table D4-13 on page D4-2031](#) shows the permitted T0SZ values for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or [VTCR\\_EL2.SL0](#) is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

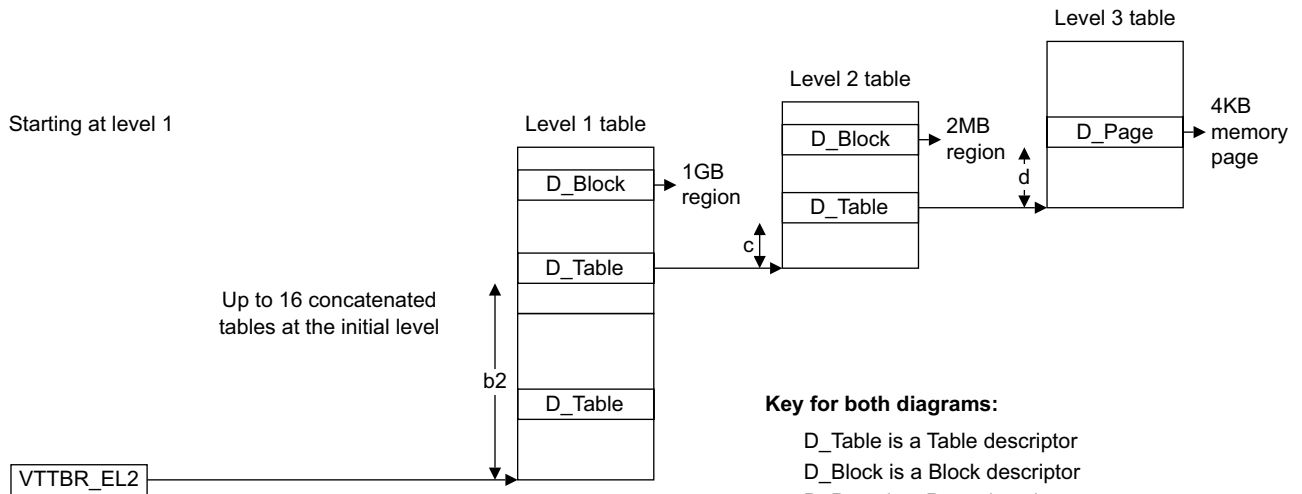

Figure D4-8 shows the stage 2 address translation, for an input address size of between 40 and 43 bits. For an input address size in this range, the lookup can start at either level 0 or level 1.

VTCR\_EL2.SL0 defines the start level.

Starting at level 0

Starting at level 1

**Key for both diagrams:**

D\_Table is a Table descriptor

D\_Block is a Block descriptor

D\_Page is a Page descriptor

a Indexed by IA[n:39], where IA width is (n+1) bits

b1 Indexed by IA[38:30]

b2 Indexed by IA[n:30], where IA width is (n+1) bits

c Indexed by IA[29:21]

d Indexed by IA[20:12]

**Figure D4-8 General view of VMSAv8-64 stage 2 address translation, 4KB granule**

## Overview of VMSAv8-64 address translation using the 16KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

### Overview of stage 1 translations, 16KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding `TCR_ELx.TnSZ` field. When using the 16KB translation granule, Table D4-15 shows this requirement.

**Table D4-15** `TCR_ELx.TnSZ` values and IA ranges, 16K granule with no concatenation of tables

Initial lookup level	TnSZ values for and input address ranges <sup>a</sup> for starting at this level			
	TnSZ <sub>min</sub>	IA <sub>max</sub>	TnSZ <sub>max</sub>	IA <sub>min</sub>
0	16	IA[47:14]	-	-
1	17	IA[46:14]	27	IA[36:14]
2	28	IA[35:14]	38	IA[25:14]
3	39	IA[24:14]	-	-

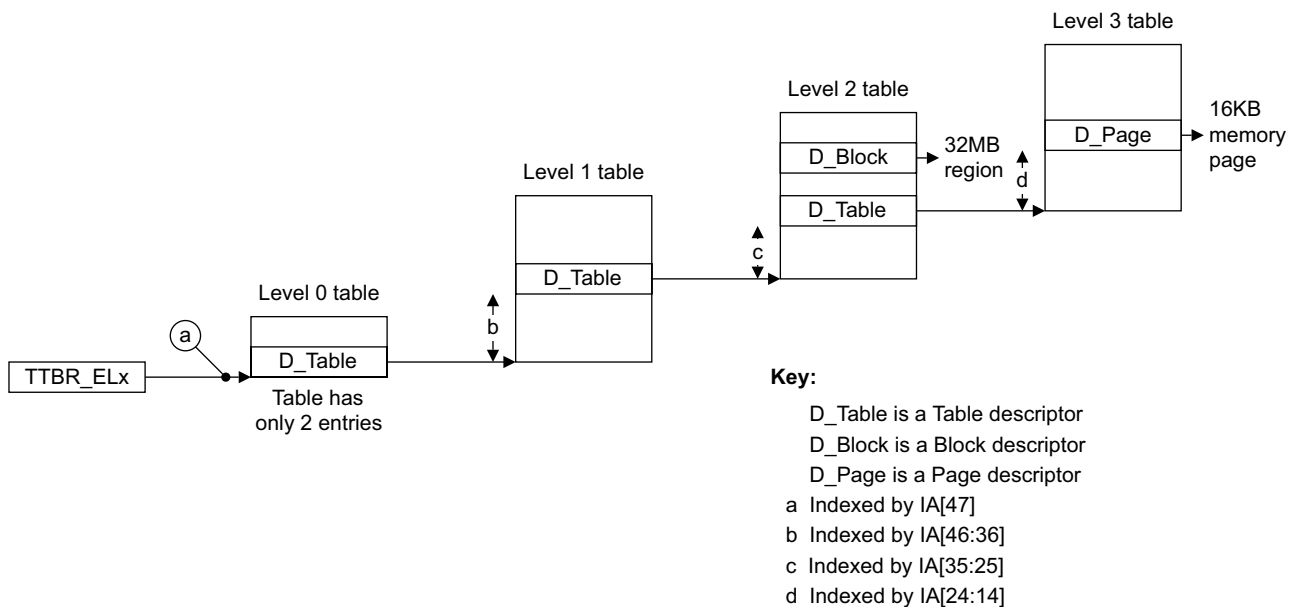

a. The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.

The configuration options for an initial lookup at level 1, level 2, or level 3 are also permitted for stage 2 translations, but stage 2 translation does not permit an initial lookup at level 0.

#### Note

- When using the 16KB translation granule, a maximum of 1 bit of IA is resolved by a level 0 lookup.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule,  $IA[13:0] = OA[13:0]$  for all translations.

Figure D4-9 shows the stage 1 address translation, for an address translation using the 16KB granule with an input address size of 48 bits.

**Figure D4-9** General view of VMSAv8-64 stage 1 address translation, 16KB granule

### Overview of stage 2 translations, 16KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see [Use of concatenated translation tables for the initial stage 2 lookup on page D4-2047](#).

When using the 16KB granule, for a stage 2 translation with an input address sized of 48 bits, the initial lookup must be at level 1, with two concatenated translation tables at this level.

When using the 16KB translation granule, [Table D4-16](#) shows all possibilities for the initial lookup for a stage 2 translation.

**Table D4-16 VTCR\_EL2.T0SZ values and IA ranges, 16K granule with possible concatenation of translation tables**

Tables <sup>a</sup>	1		2		4		8		16	
Initial lookup level	T0SZ values and input address ranges <sup>b</sup> for starting at this level									
	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
1	17-27	IA[46:14]-IA[36:14]	16	IA[47:14]	-	-	-	-	-	-
2	28-38	IA[35:14]-IA[25:14]	27	IA[36:14]	26	IA[37:14]	25	IA[38:14]	24	IA[39:14]
3	39	IA[24:14]	38	IA[25:14]	37	IA[26:14]	36	IA[27:14]	35	IA[28:14]

- a. Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, also shown in [Table D4-15 on page D4-2034](#).
- b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the *Note* that follows.

#### Note

- When using the 16KB translation granule for a stage 2 translation, the initial lookup cannot be at level 0. When a 48-bit input address is required, translation must start with a level 1 lookup using two concatenated translation tables.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

In addition, [VTCR\\_EL2.SL0](#) indicates the required initial lookup level, as [Table D4-17](#) shows.

**Table D4-17 VTCR\_EL2.SL0 values, 16KB granule**

Initial lookup level	VTCR_EL2.SL0
1	0b10
2	0b01
3	0b00

The [VTCR\\_EL2.SL0](#) value 0b11 is reserved.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted [VTCR\\_EL2.{T0SZ, SL0}](#) values. [Table D4-16](#) shows the permitted values of T0SZ for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or [VTCR\\_EL2.SL0](#) is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

When stage 2 translation supports a 48-bit input address range, translation must start with a level 1 lookup using two concatenated translation tables. Figure D4-10 shows the translation for this case.

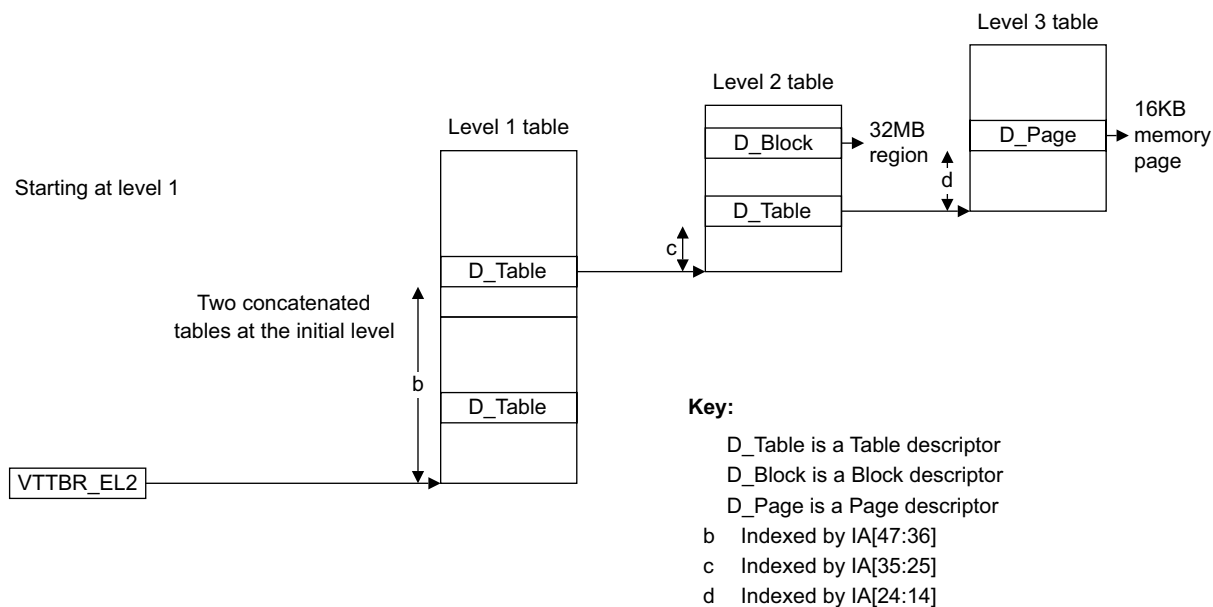

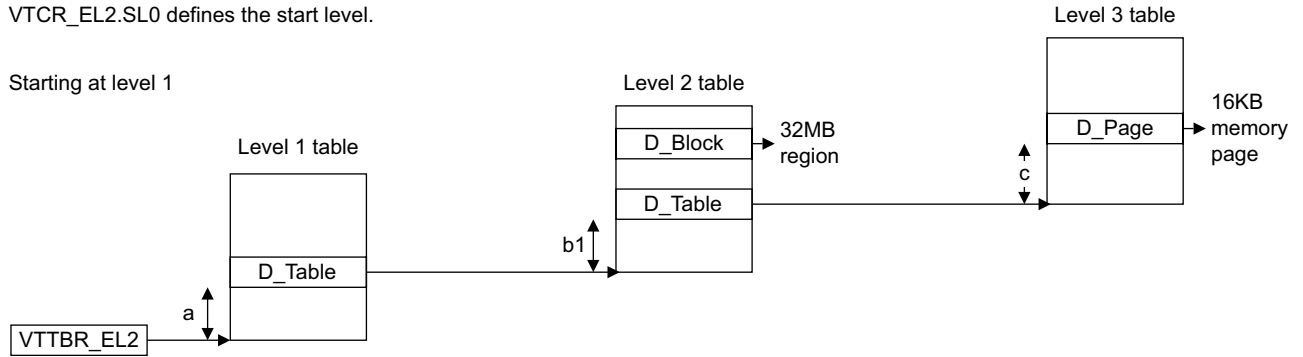

Figure D4-10 VMSAv8-64 stage 2 address translation, 16KB granule, 48 bit input address

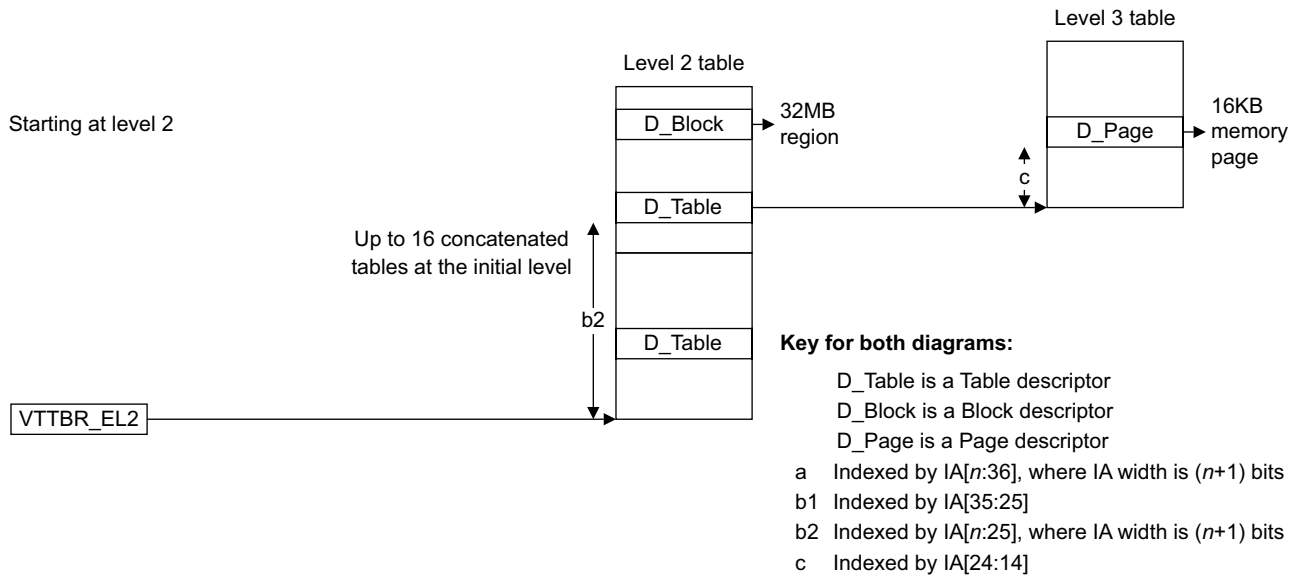

However, for an input address size of between 37 and 40 bits, [Table D4-16 on page D4-2035](#) shows that translation can start with either a level 1 lookup or a level 2 lookup, and [Figure D4-11](#) shows these options.

VTCR\_EL2.SL0 defines the start level.

Starting at level 1

Starting at level 2

**Figure D4-11 General view of VMSAv8-64 stage 2 address translation, 16KB granule**

## Overview of VMSAv8-64 address translation using the 64KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

### Overview of stage 1 translations, 64KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding `TCR_ELx.TxSZ` field. When using the 64KB translation granule, [Table D4-18](#) shows this requirement.

**Table D4-18** `TCR_ELx.TxSZ` values and IA ranges, 64K granule with no concatenation of tables

Lookup level	TxSZ values for and input address ranges <sup>a</sup> for starting at this level			
	TxSZ <sub>min</sub>	IA <sub>max</sub>	TxSZ <sub>max</sub>	IA <sub>min</sub>
1 <sup>b</sup>	12	IA[51:16]	21	IA[42:16]
1	16	IA[47:16]	21	IA[42:16]
2	22	IA[41:16]	34	IA[29:16]
3	35	IA[28:16]	39	IA[24:16]

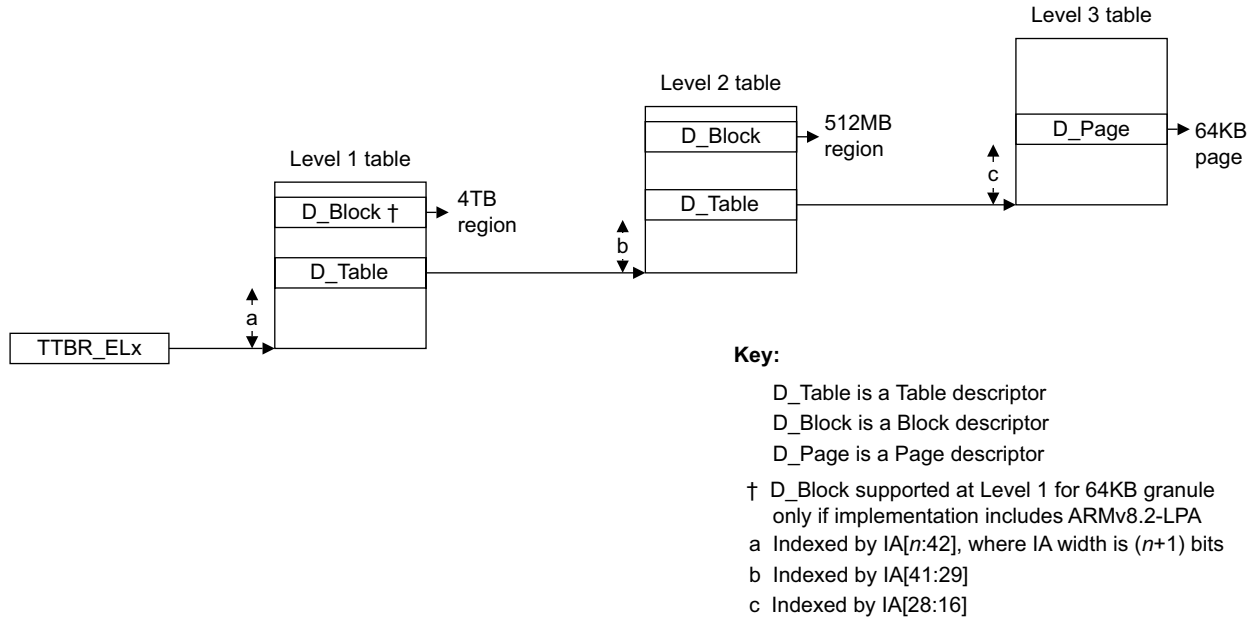

- The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.
- Supported only if ARMv8.2-LVA is implemented and the 64KB translation granule is used, see [Extending addressing above 48 bits](#) on page D4-2018.

These configuration options are also permitted for stage 2 translations.

#### **Note**

- When using the 64KB translation granule, there are no level 0 lookups.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, IA[15:0] = OA[15:0] for all translations.
- When ARMv8.2-LPA is implemented, a level 1 block attribute is supported when using the 64KB granule.

[Figure D4-12 on page D4-2039](#) shows the stage 1 address translation, for an address translation using the 64KB granule with an input address size greater than 42 bits.

**Figure D4-12 General view of VMSAv8-64 stage 1 address translation, 64KB granule with 52-bit VA support**

#### Overview of stage 2 translations, 64KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see [Use of concatenated translation tables for the initial stage 2 lookup on page D4-2047](#).

When using the 64KB translation granule, [Table D4-19](#) shows all possibilities for the initial lookup for a stage 2 translation.

**Table D4-19 VTCR\_EL2.T0SZ values and IA ranges, 64K granule with possible concatenation of translation tables**

Tables <sup>a</sup>	1		2		4		8		16	
Initial lookup level	T0SZ values and input address ranges <sup>b</sup> for starting at this level									
	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
1 <sup>c</sup>	12-21	IA[51:16]- IA[48:16]	-	-	-	-	-	-	-	-
1	16-21	IA[47:16]- IA[42:16]	-	-	-	-	-	-	-	-
2	22-34	IA[41:16]- IA[29:16]	21	IA[42:16]	20	IA[43:16]	19	IA[44:16]	18	IA[45:16]
3	35-39	IA[28:16]- IA[24:16]	34	IA[29:16]	33	IA[30:16]	32	IA[31:16]	31	IA[32:16]

a. Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, also shown in [Table D4-18 on page D4-2038](#).

b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the *Note* that follows.

c. Only supported if the PA size is 52 bits, see [Extending addressing above 48 bits on page D4-2018](#).

---

**Note**

- When using the 64KB translation granule, there are no level 0 lookups.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 64KB translation granule, tables cannot be concatenated at level 1.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule,  $IA[15:0] = OA[15:0]$  for all translations.

---

`VTCCR_EL2.SL0` indicates the required initial lookup level, as [Table D4-20](#) shows.

**Table D4-20 `VTCCR_EL2.SL0` values, 64K granule**

Initial lookup level	<code>VTCCR_EL2.SL0</code>
1	0b10
2	0b01
3	0b00

The `VTCCR_EL2.SL0` value 0b11 is reserved.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted `VTCCR_EL2.{T0SZ, SL0}` values. [Table D4-19 on page D4-2039](#) shows the permitted values of T0SZ for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or `VTCCR_EL2.SL0` is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

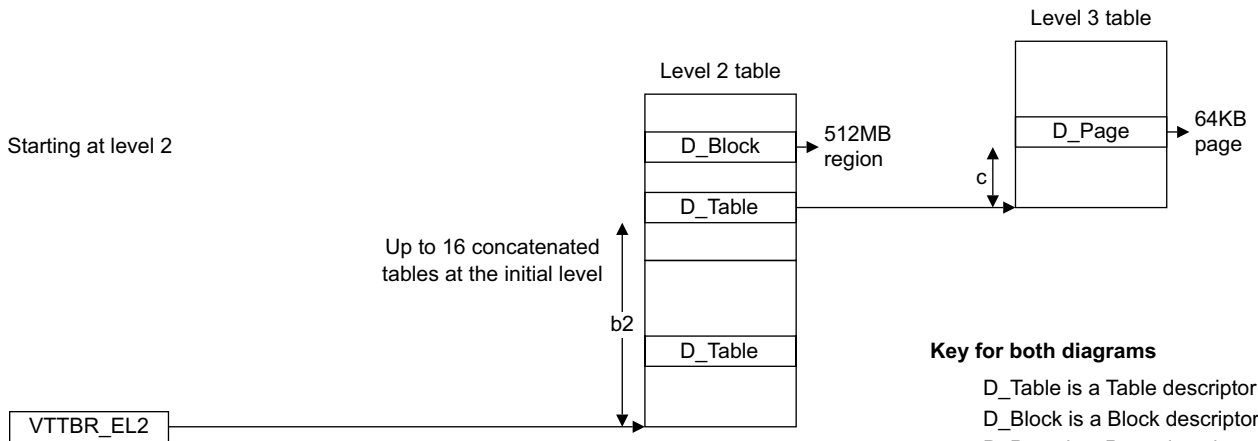

Figure D4-13 shows the stage 2 address translation, for an input address size of between 43 and 46 bits. This means the lookup can start at either level 1 or level 2.

VTCR\_EL2.SL0 defines the start level.

Starting at level 1

Starting at level 2

## D4.2.7 The VMSAv8-64 translation table format

This section provides the full description of the VMSAv8-64 translation table format, its use for address translations that are controlled by an Exception level using AArch64. For these translation regimes:

### For a stage 1 translation that supports two VA ranges

- For the lower VA range, that uses [TTBR0\\_ELx](#):
  - The [TCR\\_ELx](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
  - The [TCR\\_ELx](#).TG0 field defines the Translation granule size.
- For the upper VA range, that uses [TTBR1\\_ELx](#):
  - The [TCR\\_ELx](#).{SH1, ORGN1, IRGN1} fields define memory region attributes for the translation table walks.
  - The [TCR\\_ELx](#).TG1 field defines the Translation granule size.
- Each of [TTBR0\\_ELx](#) and [TTBR1\\_ELx](#) contains an ASID field, and the [TCR\\_ELx](#).A1 field selects which of these specifies the [ASID](#) to use.

### For a stage 1 translation that supports one VA range

The translation table walks use [TTBR0\\_ELx](#), and:

- The [TCR\\_ELx](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The [TCR\\_ELx](#).TG0 field defines the Translation granule size.

### For a stage 2 translation

The translation table walks use [VTTBR\\_EL2](#), and:

- The [VTCR\\_EL2](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The [VTCR\\_EL2](#).TG0 field defines the Translation granule size.

For the VMSAv8-64 translation table format, [Overview of the VMSAv8-64 address translation stages on page D4-2030](#) summarizes the lookup levels, and [Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats on page D4-2061](#) describes the translation table entries.

The following subsections describe the use of this translation table format:

- [Translation granule size and associated block and page sizes on page D4-2043.](#)
- [Selection between TTBR0\\_ELx and TTBR1\\_ELx when two VA ranges are supported on page D4-2045.](#)
- [Use of concatenated translation tables for the initial stage 2 lookup on page D4-2047.](#)
- [Possible errors in programming the translation table registers on page D4-2048.](#)

## Translation granule size and associated block and page sizes

Table D4-21 shows the supported granule sizes, block sizes and page sizes, for the different granule sizes. For completeness, this table includes information for AArch32 state. In the table, the OA bit ranges are the OA bits that the translation table descriptor specifies to address the block or page of memory, in an implementation that supports a 48-bit OA range.

**Table D4-21 Translation granule sizes, with block and page sizes, and output address ranges**

Granule size	Table level	Block size and OA bit range	Page size and OA bit range
4KB	Zero	-	-
	One	1GB, OA[47:30]	-
	Two	2MB, OA[47:21]	-
	Three	-	4KB, OA[47:12]
16KB	Zero	-	-
	One	-	-
	Two	32MB, OA[47:25]	-
	Three	-	16KB, OA[47:14]
64KB	One	4TB, OA[51:42] <sup>a</sup>	-
	Two	512MB, OA[47:29]	-
	Three	-	64KB, OA[47:16]

a. Only available when ARMv8.2-LPA is implemented, see *Extending addressing above 48 bits* on page D4-2018.

Bit[1] of a translation table descriptor identifies whether the descriptor is a block descriptor, and:

- The 4KB granule size supports block descriptors only in level 1 and level 2 translation tables.
- The 16KB granule size supports block descriptors only in level 2 translation tables.
- The 64KB granule size supports block descriptors in level 2 translation tables, and in level 1 translation tables when ARMv8.2-LPA is implemented and the implementation supports 52 bits of physical address. If the implementation does not support 52 bits of physical address, then encoding a block descriptor in a level 1 translation table generates a level 1 Translation fault.

If bit[1] of a descriptor is 0 in a translation table that does not support block descriptors then a translation table walk that accesses that descriptor generates a Translation fault.

For translations managed from AArch64 state, the following tables expand the information for each granule size, showing for an access to a single translation table at each lookup level:

- The maximum IA size, and the address bits that are resolved for that maximum size.
- The maximum OA range resolved by the translation table descriptors at this level, and the corresponding memory region size.
- The maximum size of the translation table. This is the size required for the maximum IA size.

Table D4-22 on page D4-2044 shows this information for the 4KB translation granule size, Table D4-23 on page D4-2044 shows this information for the 16KB translation granule size, and Table D4-24 on page D4-2044 shows this information for the 64KB translation granule size.

**Table D4-22 Properties of the address lookup levels, 4KB granule size**

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region <sup>a</sup>		
Zero	256TB	Address[47:39]	Address[47:39]	512GB	Up to 512	No
One	512GB	Address[38:30]	Address[47:30]	1GB	Up to 512	Yes
Two	1GB	Address[29:21]	Address[47:21]	2MB	Up to 512	Yes
Three	2MB	Address[20:12]	Address[47:12]	4KB	512	Page only

a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.

**Table D4-23 Properties of the address lookup levels, 16KB granule size**

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region <sup>a</sup>		
Zero	256TB	Address[47]	Address[47]	128TB	2 <sup>b</sup>	No
One	128TB	Address[46:36]	Address[47:36]	64GB	Up to 2048	No
Two	64GB	Address[35:25]	Address[47:25]	32MB	Up to 2048	Yes
Three	32MB	Address[24:14]	Address[47:14]	16KB	2048	Page only

a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.

b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.

**Table D4-24 Properties of the address lookup levels, 64KB granule size**

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region <sup>a</sup>		
One	4PB	Address[51:42]	Address[51:42]	4TB	Up to 64 <sup>b</sup>	Yes
One	256TB	Address[47:42]	Address[47:42]	4TB	Up to 64 <sup>b</sup>	No
Two	4TB	Address[41:29]	Address[47:29]	512MB	Up to 8192	Yes
Three	512MB	Address[28:16]	Address[47:16]	64KB	8192	Page only

a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.

b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.

For the initial lookup level:

- If the IA range specified by the `TCR_ELx.TxSZ` field is smaller than the maximum size shown in these table then this reduces the number of addresses in the table and therefore reduces the table size. The smaller translation table is aligned to its table size.
- For stage 2 translations, multiple translation tables can be concatenated to extend the maximum IA size beyond that shown in these tables. For more information see the stage 2 translation overviews in [Overview of the VMSAv8-64 address translation stages on page D4-2030](#) and [Use of concatenated translation tables for the initial stage 2 lookup on page D4-2047](#).

If a supplied input address is larger than the configured input address size, a Translation fault is generated.

#### ————— **Note** —————

Larger translation granule sizes typically requires fewer levels of translation tables to translate a particular size of VA.

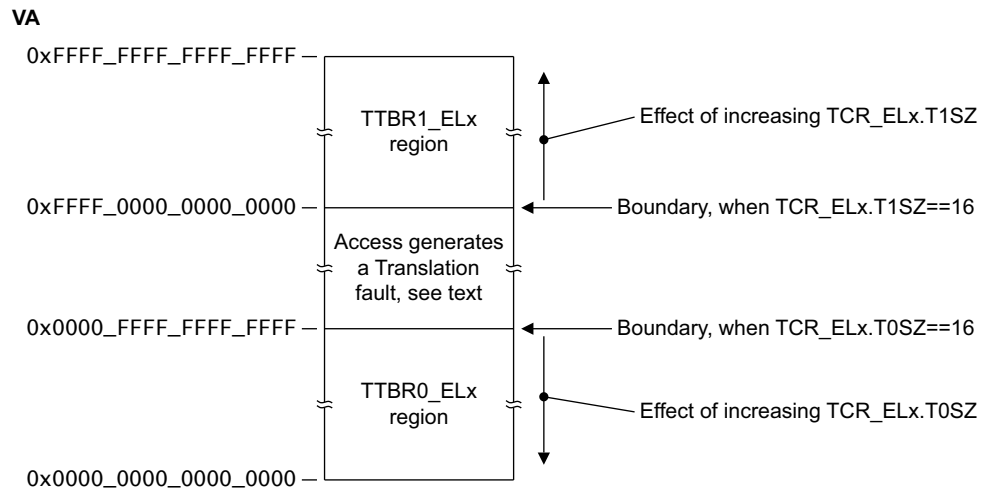

For the `TCR_ELx` programming requirements for the initial lookup, see [Overview of the VMSAv8-64 address translation stages on page D4-2030](#).

### **Selection between TTBR0\_ELx and TTBR1\_ELx when two VA ranges are supported**

Every translation table walk starts by accessing the translation table addressed by the `TTBR_ELx` for the stage 1 translation for the required translation regime.

For a stage 1 translation that supports two VA ranges, [Figure D4-14](#) shows this VA range split when using 48-bit VAs, and:

- `TTBR0_ELx` points to the initial translation table for the lower VA range, that starts at address `0x0000_0000_0000_0000`,
- `TTBR1_ELx` points to the initial translation table for the upper VA range, that runs up to address `0xFFFF_FFFF_FFFF_FFFF`.

**Figure D4-14 AArch64 TTBRn boundaries and VA ranges for 48-bit VAs**

As [Figure D4-14](#) shows, for 48-bit VAs:

- The address range translated using `TTBR0_ELx` is `0x0000_0000_0000_0000` to `0x0000_FFFF_FFFF_FFFF`.
- The address range translated using `TTBR1_ELx` is `0xFFFF_0000_0000_0000` to `0xFFFF_FFFF_FFFF_FFFF`.

In an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, for 52-bit VAs:

- The address range translated using `TTBR0_ELx` is `0x0000_0000_0000_0000` to `0x0000_FFFF_FFFF_FFFF`.
- The address range translated using `TTBR1_ELx` is `0xFFFF_0000_0000_0000` to `0xFFFF_FFFF_FFFF_FFFF`.

Which **TTBR\_ELx** is used depends only on the **VA** presented for translation. The most significant bits of the **VA** must all be the same value and:

- If the most significant bits of the **VA** are zero, then **TTBR0\_ELx** is used.
- If the most significant bits of the **VA** are one, then **TTBR1\_ELx** is used.

However, it is configurable whether **VA**[63:56] are considered when determining which **TTBR\_ELx** is used, that is:

- In an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, whether the determination depends on **VA**[63:52] or on **VA**[55:52].
- Otherwise, whether the determination depends on **VA**[63:48] or on **VA**[55:48].

For more information about whether **VA**[63:56] are considered for this determination see [Address tagging in AArch64 state on page D4-2006](#).

---

**Note**

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the **TCR\_ELx.TnSZ** values and the region for which an access generates a Translation fault is wider than shown in [Figure D4-14 on page D4-2045](#). That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. [Possible errors in programming the translation table registers on page D4-2048](#) describes this possibility.

---

[Example D4-3](#) shows a typical application of this **VA** split.

---

**Example D4-3 Example use of the split VA range, and the TTBR0\_ELx and TTBR1\_ELx controls**

---

An example of using the split **VA** range is:

**TTBR0\_ELx** Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- **TTBR0\_ELx** is updated to point to the level 1 translation table for the new context
- **TCR\_ELx** is updated if this change changes the size of the translation table
- **CONTEXTIDR\_ELx** is updated.

**TTBR1\_ELx** Used for operating system and I/O addresses, that do not change on a context switch.

---

For each **VA** subrange, the input address size is  $2^{(64-TnSZ)}$ , where **TnSZ** is one of **TCR\_ELx**.{**T0SZ**, **T1SZ**}.

This means the two **VA** subranges are:

**Lower VA subrange**  $0x0000\_0000\_0000\_0000$  to  $(2^{(64-T0SZ)} - 1)$ .

**Upper VA subrange**  $(2^{64} - 2^{(64-T1SZ)})$  to  $0xFFFF\_FFFF\_FFFF\_FFFF$ .

For the situation where the minimum **TnSZ** value is 16, corresponding to a maximum input address range of 48 bits, [Example D4-4](#) shows the two **VA** subranges when **T0SZ** and **T1SZ** are both set to this minimum value.

---

**Example D4-4 Maximum VA ranges when a stage of translation supports two ranges**

---

The maximum **VA** subranges correspond to **T0SZ** and **T1SZ** each having a minimum value of 16. In this case the subranges are:

**Lower VA subrange**  $0x0000\_0000\_0000\_0000$  to  $0x0000\_FFFF\_FFFF\_FFFF$ .

**Upper VA subrange**  $0xFFFF\_0000\_0000\_0000$  to  $0xFFFF\_FFFF\_FFFF\_FFFF$ .

---

[Figure D4-14 on page D4-2045](#) indicates the effect of varying the **TnSZ** values.

As described in [Overview of the VMSAv8-64 address translation stages on page D4-2030](#), the  $TnSZ$  values also determine the initial lookup level for the translation.

### Use of concatenated translation tables for the initial stage 2 lookup

[Overview of the VMSAv8-64 address translation stages on page D4-2030](#) introduced the ability to concatenate translation tables for the initial stage 2 translation lookup. This section gives more information about that concatenation.

If a stage 2 translation would require 16 entries or fewer in its top-level translation table, that stage of translation can, instead, be configured so that:

- It requires the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- The stage 2 translation starts at that next translation level.

When using the 16KB translation granule, if a 48-bit input address size is required for the stage 2 translations, lookup must start with two concatenated translation tables at level 1.

The use of concatenated translation tables requires the software that is defining the translation to:

- Define the concatenated translation tables with the required overall alignment.
- Program `VTTBR_EL2` to hold the address of the first of the concatenated translation tables.
- Program `VTCR_EL2` to indicate the required input address range and initial lookup level.

---

#### Note

The use of concatenated translation tables avoids the overhead of an additional level of translation.

---

Concatenating additional translation tables at the initial level of look up resolves additional address bits at that level. To resolve  $n$  additional address bits requires  $2^n$  concatenated translation tables. [Example D4-5](#) shows how, for level 1 lookups using the 4KB translation granule, translation tables can be concatenated to resolve three additional address bits.

---

### Example D4-5 Adding three bits of address resolution at level 1 lookup, using the 4KB granule

---

When using the 4KB translation granule, a level 1 lookup with a single translation table resolves address bits[38:30]. To add three more address bits requires  $2^3$  translation tables, that is, eight translation tables. This means:

- The total size of the concatenated translation tables is  $8 \times 4\text{KB} = 32\text{KB}$ .
  - This block of concatenated translation tables must be aligned to 32KB.
  - The address range resolved at this lookup level is  $A[41:30]$ , of which:
    - Bits  $A[41:39]$  select the 4KB translation table.
    - Bits  $A[38:30]$  index a descriptor within that translation table.
-

As an example of the concatenation of translation tables at the initial lookup level, when using the 4KB translation granule, [Table D4-25](#) shows the possible uses of concatenated translation tables to permit lookup to start at level 1 rather than at level 0. For completeness, the table starts with the case where the required IPA range means lookup starts at level 1 with a single translation table at that level.

**Table D4-25 Possible uses of concatenated translation tables for level 1 lookup, 4KB granule**

Configured stage 2 IA size		Lookup starts at level 0	Lookup starts at level 1	
IPA range	Size	Required level 0 entries	Number of concatenated tables	Required alignment <sup>a</sup>
IPA[38:0]	2 <sup>36</sup> bytes	-	1	4KB
IPA[39:0]	2 <sup>37</sup> bytes	2	2	8KB
IPA[40:0]	2 <sup>38</sup> bytes	4	4	16KB
IPA[41:0]	2 <sup>39</sup> bytes	8	8	32KB
IPA[42:0]	2 <sup>40</sup> bytes	16	16	64KB

a. Required alignment of the set of concatenated level 2 tables.

#### Note

Because concatenation is permitted only for a stage 2 translation, the input addresses in the table are IPAs.

[Overview of the VMSAv8-64 address translation stages on page D4-2030](#) identifies all of the possible uses of concatenation. In all cases, the block of concatenated translation tables must be aligned to the block size.

## Possible errors in programming the translation table registers

This subsection describes possible errors in programming the translation table registers.

### Misprogramming the VTCR\_EL2.{T0SZ, SL0} fields

For a stage 2 translation, the programming of the VTCR\_EL2.{T0SZ, SL0} fields must be consistent. If these fields are not consistent, or if SL0 is programmed to a reserved value, any translation table walk that uses stage 2 translation generates a stage 2 level 0 Translation fault. For more information see [Overview of the VMSAv8-64 address translation stages on page D4-2030](#).

### Misprogramming of the Contiguous bit

For more information about the Contiguous bit, and the range of translation table entries that must have the bit set to 1 to mark the entries as contiguous, see [The Contiguous bit on page D4-2094](#).

If one or more of the following errors is made in programming the translation tables, the TLB might contain overlapping entries:

- One or more of the contiguous translation table entries does not have the Contiguous bit set to 1.
- One or more of the contiguous translation table entries holds an output address that is not consistent with all of the entries pointing to the same aligned contiguous address range.
- The attributes and permissions of the contiguous entries are not all the same.

Such misprogramming of the translation tables means the output address, memory permissions, or attributes for a lookup might be corrupted, and might be equal to values that are not consistent with any of the programmed translation table values.

In some implementations, such misprogramming might also give rise to a TLB Conflict abort.

The architecture guarantees that misprogramming of the Contiguous bit cannot provide a mechanism for any of the following to occur:

- Software executing at EL1 or EL0 accessing regions of physical memory that are not accessible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.
- Software executing at EL1 or EL0 accessing regions of physical memory with attributes or permissions that are not possible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.
- Software executing in Non-secure state accessing Secure physical memory.

———— **Note** ————

Hardware implementations must ensure that use of the Contiguous bit cannot provide a mechanism for avoiding output address range checking. This might occur if a Contiguous bit block size of 0.5GB or 1GB is used in a system with the output address size configured to 4GB. The architecture permits the implemented mechanism for preventing any avoidance of output address range checking to suppress the use of the Contiguous bit for such entries in such a system.

Where the Contiguous bit is used to mark a set of blocks as contiguous, if the address range translated by a set of blocks marked as contiguous is larger than the size of the input address supported at a stage of translation used to translate that address at that stage of translation, as defined by the [TCR\\_ELx.TxSZ](#) field, then this is a programming error. An implementation is permitted, but not required, to:

- Treat such a block within a contiguous set of blocks as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation, as defined by the [TCR\\_ELx.TxSZ](#) field.
- Treat such a block within a contiguous set of blocks as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, as defined by the [TCR\\_ELx.TxSZ](#) field, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

When ARMv8.2-LVA is implemented, level 1 block descriptors for the 64KB granule do not support the Contiguous bit, and that field is RES0.

## D4.2.8 The algorithm for finding the translation table descriptors

This subsection gives the algorithms for finding the translation table descriptor that corresponds to a given IA, for each required level of lookup. The algorithms encode the descriptions of address translation given earlier in this section. The algorithm details depend on the translation granule size for the stage of address translation, see:

- [Finding the translation table descriptor when using the 4KB translation granule on page D4-2050.](#)
- [Finding the translation table descriptor when using the 16KB translation granule on page D4-2051.](#)
- [Finding the translation table descriptor when using the 64KB translation granule on page D4-2052.](#)

Each subsection uses the following terms:

<b>BaseAddr</b>	The base address for the level of lookup, as defined by: <ul style="list-style-type: none"> <li>• For the initial lookup level, the value of the appropriate <a href="#">TTBR_ELx.BADDR</a> field.</li> <li>• Otherwise, the translation table address returned by the previous level of lookup.</li> </ul>
<b>PAMax</b>	The supported <a href="#">PA</a> width, in bits.
<b>IA</b>	The supplied IA for this stage of translation.

- TnSZ** The translation table size for this stage of translation:  
**For EL1&0 stage 1** [TCR\\_EL1.T0SZ](#) or [TCR\\_EL1.T1SZ](#), as appropriate.  
**For EL1&0 stage 2** [VTCR\\_EL2.T0SZ](#).  
**For EL2 stage 1** [TCR\\_EL2.T0SZ](#).  
**For EL2&0 stage 1** [TCR\\_EL2.T0SZ](#) or [TCR\\_EL2.T1SZ](#), as appropriate.  
**For EL3 stage 1** [TCR\\_EL3.T0SZ](#).
- SL0** [VTCR\\_EL2.SL0](#). Applies to the Non-secure EL1&0 stage 2 translation only.

These subsections show only architecturally-valid programming of the [TCR\\_ELx](#). See also *Possible errors in programming the translation table registers* on page D4-2048.

### Finding the translation table descriptor when using the 4KB translation granule

[Table D4-26](#) shows the translation table descriptor address, for each level of lookup, when using the 4KB translation granule. See the start of *The algorithm for finding the translation table descriptors* on page D4-2049 for more information about terms used in the table.

**Table D4-26 Translation table entry addresses when using the 4KB translation granule**

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	Stage 2 translation	
Zero	BaseAddr[PAMax-1:x]:IA[y:39]:0b000 if <sup>a</sup> $z \leq TnSZ \leq 24$ then $x = (28 - TnSZ)$	BaseAddr[PAMax-1:x]:IA[y:39]:0b000 if $SL0^b == 2$ then if <sup>a</sup> $z \leq T0SZ \leq 24$ then $x = (28 - T0SZ)$	$y = (x + 35)$ $z = 16$
One	BaseAddr[PAMax-1:x]:IA[y:30]:0b000 if <sup>a</sup> $25 \leq TnSZ \leq 33$ then $x = (37 - TnSZ)$  else <sup>c</sup> $x = 12$	BaseAddr[PAMax-1:x]:IA[y:30]:0b000 if $SL0^b == 1$ then if <sup>a</sup> $21 \leq T0SZ \leq 33$ then $x = (37 - T0SZ)$ elsif $SL0^{b,c} == 2$ then $x = 12$	$y = (x + 26)$
Two	BaseAddr[PAMax-1:x]:IA[y:21]:0b000 if <sup>a</sup> $34 \leq TnSZ \leq 39$ then $x = (46 - TnSZ)$  else <sup>c</sup> $x = 12$	BaseAddr[PAMax-1:x]:IA[y:21]:0b000 if $SL0^b == 0$ then if <sup>a</sup> $30 \leq T0SZ \leq 39$ then $x = (46 - T0SZ)$ elsif $SL0^{b,c} > 0$ then $x = 12$	$y = (x + 17)$
Three	BaseAddr[PAMax-1:12]:IA[20:12]:0b000	BaseAddr[PAMax-1:12]:IA[20:12]:0b000	-

- a. This line indicates the range of permitted values for TnSZ, for a lookup that starts at this level, see *Overview of VMSAv8-64 address translation using the 4KB translation granule* on page D4-2030.
- b.  $SL0 == 0$  if the initial lookup is level 2,  $SL0 == 1$  if the initial lookup is level 1, and  $SL0 == 2$  if the initial lookup level is level 0.
- c. This is the case where this level of lookup is not the initial level of lookup.

[Table D4-8 on page D4-2021](#) shows how software can determine whether an implementation supports the 4KB granule size.

## Finding the translation table descriptor when using the 16KB translation granule

Table D4-27 shows the translation table descriptor address, for each level of lookup, when using the 16KB translation granule. See the start of *The algorithm for finding the translation table descriptors* on page D4-2049 for more information about terms used in the table.

**Table D4-27 Translation table entry addresses when using the 16KB translation granule**

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	Stage 2 translation	
Zero	BaseAddr[PAMax-1:4]:IA[47]:0b000 <sup>a</sup> $16 \leq TnSZ$	-	Only applies to stage 1
One	BaseAddr[PAMax-1:x]:IA[y:36]:0b000 if <sup>a</sup> $17 \leq TnSZ \leq 27$ then $x = (31 - TnSZ)$  else <sup>c</sup> $x = 14$	BaseAddr[PAMax-1:x]:IA[y:36]:0b000 if $SL0^b == 2$ then if <sup>a</sup> $16 \leq T0SZ \leq 27$ then $x = (31 - T0SZ)$	$y = (x + 32)$
Two	BaseAddr[PAMax-1:x]:IA[y:25]:0b000 if <sup>a</sup> $28 \leq TnSZ \leq 38$ then $x = (42 - TnSZ)$  else <sup>c</sup> $x = 14$	BaseAddr[PAMax-1:x]:IA[y:25]:0b000 if $SL0^b == 1$ then if <sup>a</sup> $24 \leq T0SZ \leq 38$ then $x = (42 - T0SZ)$ elsif $SL0^b, ^c == 2$ then $x = 14$	$y = (x + 21)$
Three	BaseAddr[PAMax-1:14]:IA[24:14]:0b000	BaseAddr[PAMax-1:x]:IA[y:14]:0b000 if $SL0^b == 0$ then if <sup>a</sup> $35 \leq T0SZ \leq 39$ then $x = (53 - T0SZ)$ elsif $SL0^b, ^c > 0$ then $x = 14$	$y = (x + 10)$

- a. This line indicates the range of permitted values for  $TnSZ$ , for a lookup that starts at this level, see *Overview of VMSAv8-64 address translation using the 16KB translation granule* on page D4-2034.
- b.  $SL0 == 0$  if the initial lookup is level 3,  $SL0 == 1$  if the initial lookup is level 2, and  $SL0 == 2$  if the initial lookup level is level 1.
- c. This is the case where this level of lookup is not the initial level of lookup.

Table D4-8 on page D4-2021 shows how software can determine whether an implementation supports the 16KB granule size.

## Finding the translation table descriptor when using the 64KB translation granule

Table D4-28 shows the translation table descriptor address, for each level of lookup, when using the 64KB translation granule. See the start of *The algorithm for finding the translation table descriptors* on page D4-2049 for more information about terms used in the table.

**Table D4-28 Translation table entry addresses when using the 64KB translation granule**

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	Stage 2 translation	
One	BaseAddr[PAMax-1:x]:IA[y:42]:0b000 if <sup>a</sup> $z^b \leq TnSZ \leq 21$ then $x = (25 - TnSZ)$	BaseAddr[PAMax-1:x]:IA[y:42]:0b000 if $SL0^c == 2$ then if <sup>a</sup> $z^b \leq T0SZ \leq 21$ then $x = (25 - T0SZ)$	$y = (x + 38)$ $z = 16$ or $12^b$
Two	BaseAddr[PAMax-1:x]:IA[y:29]:0b000 if <sup>a</sup> $22 \leq TnSZ \leq 34$ then $x = (38 - TnSZ)$  else <sup>d</sup> $x = 16$	BaseAddr[PAMax-1:x]:IA[y:29]:0b000 if $SL0^c == 1$ then if <sup>a</sup> $18 \leq T0SZ \leq 34$ then $x = (38 - T0SZ)$ elseif $SL0^{c,d} == 2$ then $x = 16$	$y = (x + 25)$
Three	BaseAddr[PAMax-1:x]:IA[y:16]:0b000 if <sup>a</sup> $35 \leq TnSZ \leq 39$ then $x = (51 - TnSZ)$  else <sup>d</sup> $x = 16$	BaseAddr[PAMax-1:x]:IA[y:16]:0b000 if $SL0^c == 0$ then if <sup>a</sup> $31 \leq T0SZ \leq 39$ then $x = (51 - T0SZ)$ elseif $SL0^{c,d} > 0$ then $x = 16$	$y = (x + 12)$

a. This line indicates the range of permitted values for  $TnSZ$ , for a lookup that starts at this level, see *Overview of VMSAv8-64 address translation using the 64KB translation granule* on page D4-2038.

b. If ARMv8.2-LVA is implemented, the value of  $z$  is 12, see *Extending addressing above 48 bits* on page D4-2018. Otherwise, the value of  $z$  is 16.

c.  $SL0 == 0$  if the initial lookup is level 3,  $SL0 == 1$  if the initial lookup is level 2, and  $SL0 == 2$  if the initial lookup level is at level 1.

d. This is the case where this level of lookup is not the initial level of lookup.

Table D4-8 on page D4-2021 shows how software can determine whether an implementation supports the 64KB granule size.

## D4.2.9 The effects of disabling a stage of address translation

The following sections describe the effect on MMU behavior of disabling each stage of translation:

- [Behavior when stage 1 address translation is disabled.](#)
- [Behavior when stage 2 address translation is disabled on page D4-2054.](#)
- [Behavior of instruction fetches when all associated stages of translation are disabled on page D4-2054.](#)

### Behavior when stage 1 address translation is disabled

When a stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of translation are treated as follows:

#### Non-secure EL1 and EL0 accesses if the [HCR\\_EL2.DC](#) bit is set to 1

For the Non-secure EL1&0 translation regime, when the value of [HCR\\_EL2.DC](#) is 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes.

#### ———— Note —————

This applies for both instruction and data accesses.

#### All other accesses

For all other accesses, when stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

##### Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

##### Instruction access

The stage 1 translation assigns the Normal memory attribute, with the cacheability and shareability attributes determined by the value of the [SCTLR\\_ELx.I](#) bit for the translation regime, as follows:

##### When the value of I is 0

The stage 1 translation assigns the Non-cacheable and Outer Shareable attributes.

##### When the value of I is 1

The stage 1 translation assigns the Cacheable, Inner Write-Through Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Outer Shareable attribute.

For this stage of translation, no memory access permission checks are performed. Therefore no MMU faults can be generated for this stage of address translation.

#### ———— Note —————

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, the input address of the stage 1 translation is flat-mapped to the output address.

For a Non-secure EL1 or EL0 access, if EL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

When the value of [HCR\\_EL2.DC](#) is 1, in Non-secure state:

- The [SCTLR\\_EL1.M](#) bit behaves as if it is 0, for all purposes other than reading the value of the bit. This means Non-secure EL1&0 stage 1 address translation is disabled.
- The [HCR\\_EL2.VM](#) bit behaves as if it is 1, for all purposes other than reading the value of the bit. This means that Non-secure EL1&0 stage 2 address translation is enabled.

See also [Behavior of instruction fetches when all associated stages of translation are disabled on page D4-2054.](#)

### **Effect of disabling address translation on maintenance and address translation instructions**

Cache maintenance instructions act on the target cache regardless of whether any stages of address translation are disabled, and regardless of the values of the memory attributes. However, if a stage of address translation is disabled, they use the flat address mapping for that translation stage.

TLB invalidate operations act on the target TLB regardless of whether any stage of address translation is disabled.

The value of [HCR\\_EL2.DC](#) affect some address translation instructions, see [Address translation instructions, AT\\*](#) on page D4-2056.

### **Behavior when stage 2 address translation is disabled**

When stage 2 address translation is disabled:

- The [IPA](#) output from the stage 1 translation maps flat to the [PA](#).
- The memory attributes and permissions from the stage 1 translation apply to the [PA](#).

When both stages of address translation are disabled, see also [Behavior of instruction fetches when all associated stages of translation are disabled](#).

### **Behavior of instruction fetches when all associated stages of translation are disabled**

When EL3 is using AArch64, this section applies to:

- The Secure EL1&0 translation regime when stage 1 address translation is disabled in that regime.
- The Secure EL3 translation regime when stage 1 address translation is disabled in that regime.
- The Non-secure EL2, or EL2&0, translation regime when stage 1 address translation is disabled in that regime
- The Non-secure EL1&0 translation regime, when both stages of address translation are disabled.

#### **Note**

- The behaviors in Non-secure state apply regardless of the Execution state that EL3 is using.
- When the value of [HCR\\_EL2.DC](#) is 1, then the behavior of the Non-secure EL1&0 translation regime is as if stage 1 translation is disabled and stage 2 translation is enabled, as described in [Behavior when stage 1 address translation is disabled on page D4-2053](#).

In these cases, when execution is in AArch64 state, a memory location might be accessed as a result of an instruction fetch if either:

- The memory location is in the same block of memory as, or in the next contiguous block of memory to, an instruction that a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset.
- The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
  - The last reset.
  - The last synchronization of instruction cache maintenance targeting the address of the branch instruction.

In this description, the blocks of memory referred to are of the size of the minimum implemented translation granule and are aligned to that size.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

---

**Note**

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when all associated stages of address translation are disabled are located in blocks of the address space, of the translation granule size, that contain only memory that is tolerant to speculative accesses.
  - Each block of the address space, of the translation granule size, that immediately follows a similar block that holds instructions that will be executed when all associated stages address translation are disabled, contains only memory that is tolerant to speculative accesses.
- 

## D4.2.10 Pseudocode description of VMSAv8-64 address translation

The following subsections outline a pseudocode description of the translation table walk:

- [Definitions required for address translation.](#)
- [Performing the full address translation.](#)
- [Stage 1 translation.](#)
- [Stage 2 translation.](#)
- [Translation table walk.](#)
- [Support functions on page D4-2056.](#)

### Definitions required for address translation

In pseudocode, the result of a translation table lookup, in either Execution state, is returned in a [TLBRecord](#) structure.

[Memory data type definitions on page D3-2000](#) includes definitions of the Permissions and AddressDescriptor parameters.

### Performing the full address translation

The function [AArch64.FullTranslate\(\)](#) performs a full translation table walk. For any translation regime it performs a stage 1 translation for the supplied [VA](#), and for the Non-secure EL1&0 translation regime it then performs a stage 2 translation of the returned address.

### Stage 1 translation

The function [AArch64.FirstStageTranslate\(\)](#) performs a stage 1 translation, calling the function [AArch64.TranslationTableWalk\(\)](#), described in [Translation table walk](#), to perform the required translation table walk. However, if stage 1 translation is disabled, it calls the function [AArch64.TranslateAddressS10ff\(\)](#) to set the memory attributes.

### Stage 2 translation

In the Non-secure EL1&0 translation regime, a descriptor address returned by stage 1 lookup is in the [IPA](#) address space, and must be mapped to a [PA](#) by a stage 2 translation. Function [AArch64.SecondStageWalk\(\)](#) performs this translation, by calling the [AArch64.SecondStageTranslate\(\)](#) function. When called from [AArch64.SecondStageWalk\(\)](#), the [AArch64.SecondStageTranslate\(\)](#) function performs a second stage translation, from [IPA](#) to [PA](#), of the supplied address, including checking that the access has read permission at the second stage. If the access does not have second stage read permission it generates a second stage Permission fault on the first stage translation table walk. The second stage translation might hit in a TLB, or might involve a translation table walk, which will use the algorithm described in this section.

### Translation table walk

The function [AArch64.TranslationTableWalk\(\)](#) returns the result, in the form of a [TLBRecord](#), of a translation table walk made for a memory access from an Exception level that is using AArch64.

## Support functions

In the translation table walk functions, the [WalkAttrDecode\(\)](#) function determines the attributes for a translation table lookup.

The function [AArch64.S1AttrDecode\(\)](#) decodes the attributes from a stage 1 translation table lookup.

The function [AArch64.CheckPermission\(\)](#) checks the access permissions returned by a stage 1 translation table lookup, see [Access permission checking on page D3-2002](#).

The function [AArch64.CheckS2Permission\(\)](#) checks the access permissions returned by a stage 2 translation table lookup.

The function [AddrTop\(\)](#) returns the bit number of the most significant valid bit of a [VA](#) in the current translation regime. If EL1 is using AArch64 and EL0 is using AArch32 then an address from EL0 is zero-extended to 64 bits.

### D4.2.11 Address translation instructions

Each of the ARMv8 instruction sets provides instructions that return the result of translating an input address, supplied as an argument to the instruction, using a specified translation stage or regime.

The available instructions only perform translations that are accessible from the Security state and Exception level at which the instruction is executed. That is:

- No instruction executed in Non-secure state can return the result of a Secure address translation stage.
- No instruction can return the result of an address translation stage that is controlled by an Exception level that is higher than the Exception level at which the instruction is executed.

[Address translation instructions, AT\\*](#) summarizes the A64 address translation instructions.

See also [A64 system instructions for address translation on page C5-427](#).

#### Address translation instructions, AT\*

The A64 assembly language syntax for address translation instructions is:

AT <operation>, <Xt>

Where:

<operation> Is one of S1E1R, [S1E1RP](#), S1E1W, [S1E1WP](#), S1E0R, S1E0W, S1E1R, S1E1W, S1E0R, S1E0W, S1E2R, S1E2W, S1E3R, or S1E3W.

<operation> has a structure of <stages><level><read|write><pan>, where:

<stages> Is one of:

S1 Stage 1 translation.  
S12 Stage 1 translation followed by stage 2 translation.

<level> Describes the Exception Level that the translation applies to. Is one of:

E0 EL0.  
E1 EL1.  
E2 EL2.  
E3 EL3.

If <level> is higher than the current Exception Level, the instruction is UNDEFINED.

<read|write>

Is one of:

R Read.  
W Write.

<pan>

Only available when ARMv8.2-ATS1E1 is implemented. Optional, but if present:

P Determines action based on value of PSTATE.PAN.

Only permitted for <stages>=S1 and <level>=E1.

<Xt> The address to be translated. No alignment restrictions apply for the address.

If EL2 is not implemented, the AT S1E2R and AT S1E2W instructions are UNDEFINED.

---

**Note**

If EL2 is not implemented but EL3 is implemented, the AT S1E\*\* instructions are not UNDEFINED, but behave the same way as the equivalent AT S1E\*\* instructions. This is consistent with the behavior if EL2 is implemented but stage 2 translation is disabled.

---

In each case, the address being translated is held in the 64-bit address argument register, Xt. If the address translation instruction uses a translation regime that is using AArch32, meaning it requires a VA of only 32 bits, then VA[63:32] is RES0.

If the address translation is successful, the resulting PA is returned in PAR\_EL1.PA, and PAR\_EL1.F is set to 0 to indicate that the translation was successful. Otherwise, see *Synchronous faults generated by address translation instructions*.

---

**Note**

The architecture provides a single PAR, PAR\_EL1, that is used regardless of:

- The Exception level at which the instruction was executed.
  - The Exception level that controls the stage or stages of translation used by the instruction.
- 

For all of these instructions, the current context information determines which entries in TLB caching structures are used, and how the translation table walk is performed. However, it is IMPLEMENTATION DEFINED whether the Address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, ARM recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

If EL3 is implemented, then for instructions that apply to the EL1 or EL0 Exception level, SCR\_EL3.NS determines the translation regime to which the instruction applies, as follows:

SCR\_EL3.NS == 0 Secure EL1&0 translation regime.

SCR\_EL3.NS == 1 Non-secure EL1&0 translation regime.

All relevant context information used for the translation depends on this determination.

When Non-secure EL1&0 stage 1 address translation is disabled, any AT S1E0\*, AT S1E1\*, AT S1E0\*, or AT S1E1\* address translation instruction that accesses the Non-secure state translation reflects the effect of the HCR\_EL2.DC bit as described in *Behavior when stage 1 address translation is disabled on page D4-2053*.

Executing AT S1E2R or AT S1E2W at EL3 with SCR\_EL3.NS==0 is UNDEFINED.

---

**Note**

AT S1E\*\* instructions at EL3 with SCR\_EL3.NS==0 are not UNDEFINED but behave the same way as the equivalent AT S1E\*\* instructions.

---

### ***Synchronous faults generated by address translation instructions***

The address translation instructions use the translation mechanism, and that mechanism can generate the following synchronous faults:

- Translation fault.
- Access flag fault.
- Permission fault.
- Domain fault, when translating using the AArch32 translation systems.
- Address size fault.
- TLB conflict fault.
- Synchronous external aborts during a translation table walk.

In addition:

- If the address translation instruction requires two stages of translation then these faults could arise from either stage 1 or stage 2.
- For a stage 1 translation for the Non-secure EL1&0 translation regime, the fault might be generated on the stage 2 translation of an address accessed as part of the stage 1 translation table walk, see [Stage 2 fault on a stage 1 translation table walk on page D4-2109](#).

Except as described in this section, these faults are not taken as an exception for the address translation instructions, but instead the [PAR\\_EL1.FST](#) field holds the Fault status information. In these cases the [PAR\\_EL1.PA](#) field does not hold the output address of the translation.

The exceptions to this reporting the fault in [PAR\\_EL1](#) are:

- Synchronous external aborts during a translation table walk are taken as a Data Abort exception.  
For an address translation instruction executed at a particular Exception level, if the synchronous external abort is generated on a stage 1 translation table walk, the Data Abort exception is taken to the Exception level to which a synchronous external abort on a stage 1 translation table walk for a memory access from that Exception level would be taken.

If the synchronous external abort is generated on a stage 2 translation table walk then:

- If the address translation instruction was executed at EL3, the synchronous Data Abort exception is taken to EL3.
- If the address translation instruction was executed at EL2 or EL1, the Data Abort exception is taken to the Exception level to which a synchronous external abort on a stage 2 translation table walk for a memory access from that Exception level would be taken.

In any case where the address translation instruction causes a synchronous Data Abort exception to be taken:

- The [PAR\\_EL1](#) is UNKNOWN.
- The [ESR\\_ELx](#) of the target Exception Level of the exception indicates that the fault was due to a translation table walk for a cache maintenance instruction.
- The [FAR\\_ELx](#) of the target Exception Level holds the [VA](#) for the translation request.
- For the AT S1E0\* and AT S1E1\* instructions executed from the Non-secure EL1 Exception level, if there is a synchronous stage 2 fault on a memory access made as part of the translation table walk then if the value of [SCR\\_EL3.EA](#) is 1 then a synchronous external abort on a stage 2 translation table walk is taken to EL3. In all other cases of a synchronous stage 2 fault on a memory access made as part of the translation table walk, the fault is taken as an exception to EL2, and:
  - [PAR\\_EL1](#) is UNKNOWN
  - [ESR\\_EL2](#) indicates that the fault occurred on a translation table walk, and that the operation that faulted was a cache maintenance instruction.
  - [HPFAR\\_EL2](#) holds the [IPA](#) that faulted
  - [FAR\\_EL2](#) holds the [VA](#) that the executing software supplied to the address translation instruction.

This fault can occur for any of the following reasons:

- Stage 2 Translation fault.
- Stage 2 Access fault.
- Stage 2 Permission fault.
- Stage 2 Address size fault.
- Synchronous external abort on a stage 2 translation table walk.

### **Synchronization requirements of the address translation instructions**

Where an instruction results in an update to a System register, as is the case with the AT \* address translation instructions, explicit synchronization must be performed before the result is guaranteed to be visible to subsequent direct reads of the [PAR\\_EL1](#).

---

#### **Note**

This is consistent with the AArch32 requirement, where the [VA](#) to [PA](#) translation instructions are executed as writes to the (coproc==0b1111) System register encoding space, and the effect of those writes to other registers require explicit synchronization before the result is guaranteed to be visible to subsequent instructions.

---

## D4.3 VMSAv8-64 translation table format descriptors

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the ARMv8 translation table descriptor formats:

- [VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats](#).
- [ARMv8 translation table level 3 descriptor formats on page D4-2063](#).

[Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-2064](#) then gives more information about the descriptor attribute fields, and [Control of Secure or Non-secure memory access on page D4-2070](#) describe how the NS and NSTable together control whether a memory access from Secure state accesses the Secure memory map or the Non-secure memory map.

### D4.3.1 VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats

In the VMSAv8-64 translation table format, the difference in the formats of the level 0, level 1 and level 2 descriptors is:

- Whether a block entry is permitted.
- If a block entry is permitted, the size of the memory region described by that entry.

These differences depend on the translation granule, as follows:

**4KB granule** A level 0 descriptor does not support block translation.

A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

**16KB granule** Level 0 and level 1 descriptors do not support block translation.

A block entry in a level 2 table describes the mapping of the associated 32MB input address range.

**64KB granule** Level 0 lookup is not supported.

If ARMv8.2-LPA is implemented with 52 bits of physical address space, a block entry in a level 1 table describes the mapping of the associated 4TB input address range. A level 1 descriptor does not support block translation if ARMv8.2-LPA is not implemented.

A block entry in a level 2 table describes the mapping of the associated 512MB input address range.

Figure D4-15 on page D4-2061 shows the ARMv8 level 0, level 1, and level 2 descriptor formats:

In an implementation that includes ARMv8.2-LPA, when the 64KB granule is used, the Block and Table descriptors are redefined as Figure D4-15 on page D4-2061 shows:

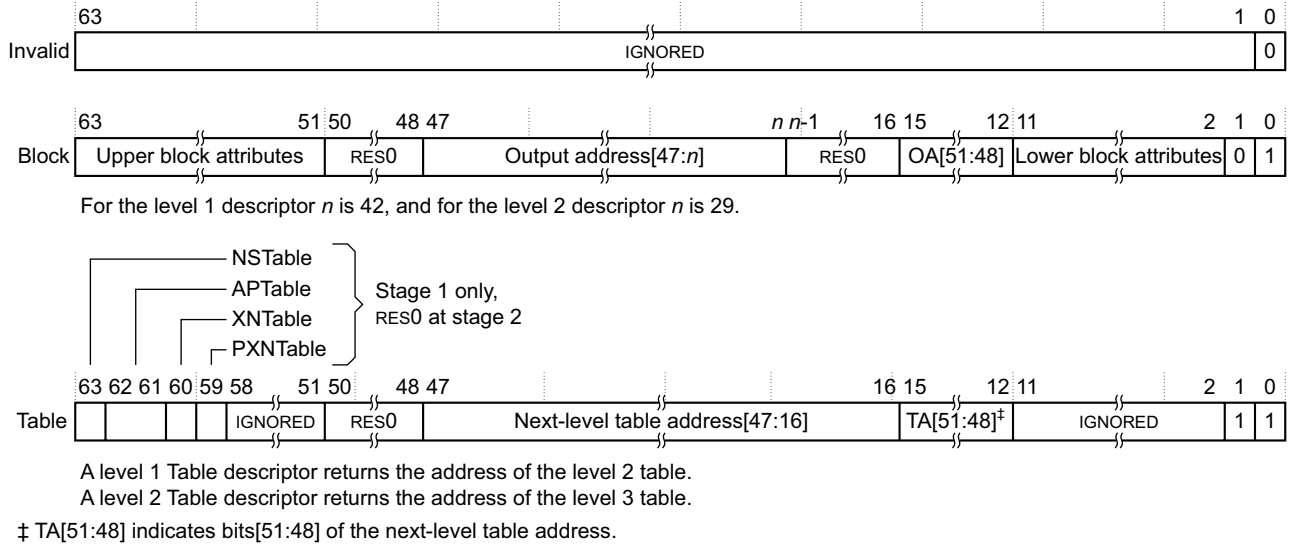

Figure D4-15 VMSAv8-64 level 1 and level 2 descriptor formats, 64KB granule

## Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- 0, Block** The descriptor gives the base address of a block of memory, and the attributes for that memory region.
- 1, Table** The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

### Block descriptor

Gives the base address and attributes of a block of memory, as follows:

#### 4KB translation granule

- For a level 1 Block descriptor, bits[47:30] are bits[47:30] of the output address. This output address specifies a 1GB block of memory.
- For a level 2 descriptor, bits[47:21] are bits[47:21] of the output address. This output address specifies a 2MB block of memory.

#### 16KB translation granule

For a level 2 Block descriptor, bits[47:25] are bits[47:25] of the output address. This output address specifies a 32MB block of memory.

#### 64KB translation granule

For a level 1 Block descriptor:

- If ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] of the output address and bits[47:42] are bits [47:42] of the output address. This output address specifies a 4TB block of memory.
- If ARMv8.2-LPA is not implemented, there is no level 1 Block descriptor.

For a level 2 Block descriptor:

- If ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] of the output address, and bits[47:29] are bits [47:29] of the output address. This output address specifies a 512MB block of memory.
- If ARMv8.2-LPA is not implemented, bits[47:29] are bits[47:29] of the output address. This output address specifies a 512MB block of memory.

In ARMv8.0, bits[63:52, 11:2] provide attributes for the target memory block. When ARMv8.1-TTHM is implemented, bits[63:51, 11:2] provide the attributes for the target memory block. For more information, see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-2064. The position and contents of these bits are identical in the level 2 block descriptor and in the level 3 page descriptor.

### Table descriptor

Gives the translation table address for the next-level lookup, as follows:

#### 4KB translation granule

- Bits[47:12] are bits[47:12] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[11:0] of the table address are zero.

#### 16KB translation granule

- Bits[47:14] are bits[47:14] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[13:0] of the table address are zero.

#### 64KB translation granule

- Bits[47:16] are bits[47:16] of the address of the required next-level table, which is:
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.

When ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] of the required next-level table.
- Bits[15:0] of the table address are zero.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-2064.

If the translation table defines the Non-secure EL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

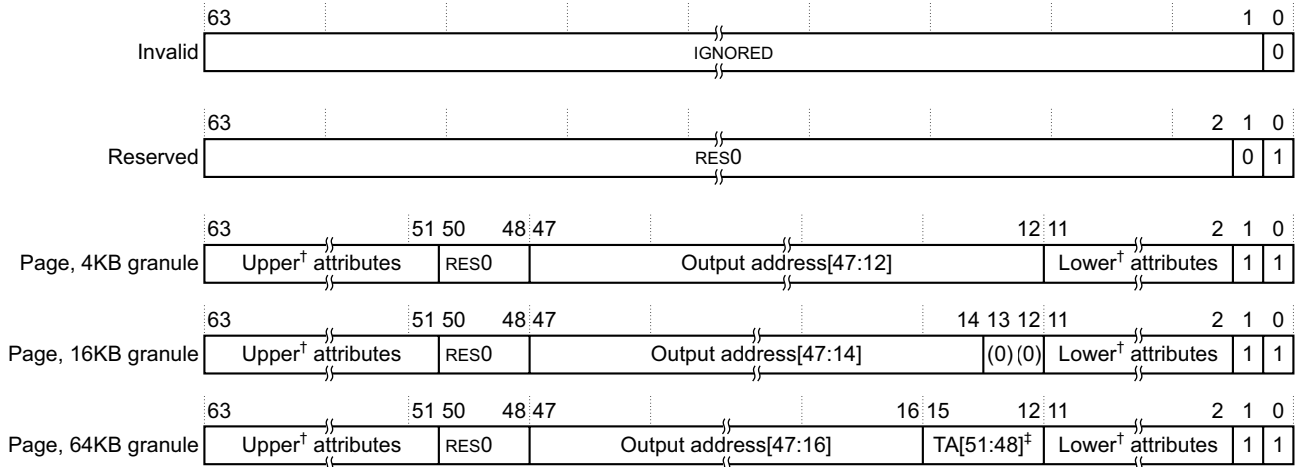

### D4.3.2 ARMv8 translation table level 3 descriptor formats

For the 4KB granule size, each entry in a level 3 table describes the mapping of the associated 4KB input address range.

For the 16KB granule size, each entry in a level 3 table describes the mapping of the associated 16KB input address range.

For the 64KB granule size, each entry in a level 3 table describes the mapping of the associated 64KB input address range.

Figure D4-16 shows the ARMv8 level 3 descriptor formats.

<sup>†</sup> Upper page attributes and Lower page attributes

<sup>‡</sup> TA[51:48] indicates bits[51:48] of the page address.

**Figure D4-16 VMSAv8-64 level 3 descriptor format**

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

#### 0, Reserved, invalid

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in level 3 translation tables.

#### 1, Page

Gives the address and attributes of a 4KB, 16KB, or 64KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

#### Page descriptor

Gives the output address of a page of memory, as follows:

##### 4KB translation granule

Bits[47:12] are bits[47:12] of the output address for a page of memory.

##### 16KB translation granule

Bits[47:14] are bits[47:14] of the output address for a page of memory.

##### 64KB translation granule

If ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] and bits[47:16] are bits[47:16] of the output address for a page of memory.

If [ARMv8.2-LPA](#) is not implemented, bits[47:16] are bits[47:16] of the output address for a page of memory.

Bits[63:52, 11:2] provide attributes for the target memory page, see [Memory attribute fields in the VMSAv8-64 translation table format descriptors](#).

#### Note

- In ARMv8.0, the position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the level 0, level 1, and level 2 block descriptors.
- When [ARMv8.1-TTHM](#) is implemented, the position and contents of bits[63:51, 11:2] are identical to bits[63:51, 11:2] in the level 0, level 1, and level 2 block descriptors.
- When [ARMv8.2-TTPBHA](#) is implemented, hardware can use bits[62:59] of the level 3 descriptor for an IMPLEMENTATION DEFINED purpose. See [Memory attribute fields in the VMSAv8-64 translation table format descriptors](#).

For the Non-secure EL1&0 stage 1 translations, the output address in the descriptor is the [IPA](#) of the target page. Otherwise, it is the [PA](#) of the target page.

### D4.3.3 Memory attribute fields in the VMSAv8-64 translation table format descriptors

[Memory region attributes on page D4-2090](#) describes the region attribute fields. The following subsections summarize the descriptor attributes as follows:

#### Table descriptor

Table descriptors for stage 2 translations do not include any attribute field. For a summary of the attribute fields in a stage 1 table descriptor, that define the attributes for the next lookup level, see [Next-level attributes in stage 1 VMSAv8-64 Table descriptors](#).

#### Block and page descriptors

These descriptors define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:

- [Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors on page D4-2066](#)
- [Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors on page D4-2068](#).

### Next-level attributes in stage 1 VMSAv8-64 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the attributes for the next-level translation table access, and bits[58:51] are IGNORED:

Next-level descriptor attributes, stage 1 only

† UXN for a translation regime that applies to execution at EL0, XN for the other regimes.  
‡ RES0 for a translation regime that does not apply to execution at EL0.

These attributes are:

#### NSTable, bit[63]

For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see [Hierarchical control of Secure or Non-secure memory accesses on page D4-2070](#).

For memory accesses from Non-secure state, including all accesses in the EL2 or EL2&0 translation regime, this bit is RES0 and is ignored by the PE.

#### APTable, bits[62:61]

Access permissions limit for subsequent levels of lookup, see [Hierarchical control of data access permissions on page D4-2074](#).

APTable[0] is RES0:

- In the EL2 translation regime.

##### **Note**

In an implementation that includes [ARMv8.1-VHE](#), when the value of [HCR\\_EL2.E2H](#) is 1 the translation regime for memory accesses from EL2 is the EL2&0 translation regime. APTable[0] can be valid (not RES0) in the EL2&0 translation regime.

- In the EL3 translation regime.

From ARMv8.1, when [ARMv8.1-HPD](#) is implemented, this field can be disabled. When the value of [TCR\\_ELx.HPD{0}](#) or [TCR\\_ELx.HPD1](#) is 1:

- The value of the corresponding APTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding APTable field is 0.

#### UXNTable or XNTable, bit[60]

XN limit for subsequent levels of lookup, see [Hierarchical control of instruction fetching on page D4-2079](#).

The naming of this field depends on whether the stage 1 translation supports two VA ranges:

##### **Two VA ranges supported**

This field is UXNTable, and determines whether execution at EL0 of instructions fetched from the region identified at a lower level of lookup permitted.

##### **Note**

PXNTable is the equivalent control of execution at a higher Exception level.

##### **One VA range supported**

This field is XNTable.

From ARMv8.1, when [ARMv8.1-HPD](#) is implemented, this field can be disabled. When the value of [TCR\\_ELx.HPD{0}](#) or [TCR\\_ELx.HPD1](#) is 1:

- The value of the corresponding UXNTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding UXNTable field is 0.

#### PXNTable, bit[59]

PXN limit for subsequent levels of lookup, see [Hierarchical control of instruction fetching on page D4-2079](#).

This field is valid only for a stage 1 translation that supports two VA ranges. It is RES0 for stage 1 translations that support only one VA range.

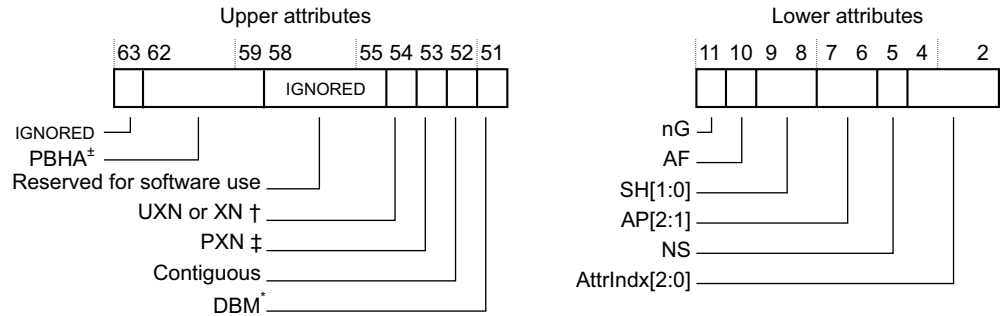

From ARMv8.1, when [ARMv8.1-HPD](#) is implemented, this field can be disabled. When the value of [TCR\\_ELx.HPD{0}](#) or [TCR\\_EL1.HPD1](#) is 1:

- The value of the corresponding PXNTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding PXNTable field is 0.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-6341](#). For more information about these fields see [Other fields in the VMSAv8-64 translation table format descriptors on page D4-2093](#).

## Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 1 translation:

<sup>±</sup> IGNORED in ARMv8.0 and ARMv8.1.

<sup>†</sup> UXN for a translation regime that applies to execution at EL0, XN for the other regimes.

<sup>‡</sup> RES0 for a translation regime that does not apply to execution at EL0.

<sup>\*</sup> RES0 in ARMv8.0.

For a stage 1 descriptor, the attributes are:

### PBHA, bits[62:59]

Page based hardware attributes bits.

These bits are IGNORED in descriptors at any level above level 3, and are IGNORED in level 3 descriptors in an implementation that does not include ARMv8.2-TTPBHA.

In an implementation that includes ARMv8.2-TTPBHA, each TCR\_ELx has a control bit for each PBHA bit in the translation tables that it controls. When the value of that control bit is 1, and the value of the corresponding Hierarchical permission disables bit, TCR\_ELx.HPD{n} is 1, hardware can use that PBHA bit for IMPLEMENTATION DEFINED purposes.

The TCR\_ELx control bits for this feature are:

#### For a translation regime that supports only a single VA range

**HWU0nn** Controls whether level 3 descriptor bit[nn] can be used by hardware. These controls apply only when the value of TCR\_ELx.HPD0 is 1.

#### For a translation regime that supports two VA ranges

**HWU0nn** For the translation tables indicated by TTBR0\_ELx, controls whether descriptor bit[nn] can be used by hardware. These controls apply only when the value of TCR\_ELx.HPD0 is 1.

**HWU1nn** For the translation tables indicated by TTBR1\_ELx, controls whether descriptor bit[nn] can be used by hardware. These controls apply only when the value of TCR\_ELx.HPD1 is 1.

If ARMv8.2-TTPBHA is not implemented, then the TCR\_ELx control bits are RAZ/WI.

### UXN or XN, bit[54]

The Execute-never bit. Determines whether the region is executable, see [Access permissions for instruction execution on page D4-2075](#).

The naming of this field depends on whether the stage 1 translation supports two VA ranges:

#### Two VA ranges supported

This field is UXN (Unprivileged execute-never), and determines whether execution at EL0 of instructions fetched from the region is permitted.

#### Note

PXN is the equivalent control of execution at a higher Exception level.

### One VA range supported

This field is XN (Execute-never).

**PXN, bit[53]** The Privileged execute-never bit. Determines whether the region is executable at EL1, see [Access permissions for instruction execution on page D4-2075](#).

This field is valid only for a stage 1 translation that supports two VA ranges. It is RES0 for stage 1 translations that support only one VA range.

### Contiguous, bit[52]

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see [The Contiguous bit on page D4-2094](#).

**DBM, bit[51]** Dirty Bit Modifier, see [The dirty state bit on page D4-2081](#).

**nG, bit[11]** The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all ASID values, or only to the current ASID value. See [Global and process-specific translation table entries on page D4-2116](#).

This field is valid only for a stage 1 translation that supports two VA ranges. It is RES0 for stage 1 translations that support only one VA range.

**AF, bit[10]** The Access flag, see [The Access flag on page D4-2081](#).

**SH, bits[9:8]** Shareability field, see [Memory region attributes on page D4-2090](#).

### AP[2:1], bits[7:6]

Data Access Permissions bits, see [Memory access control on page D4-2071](#).

#### ———— Note ————

The ARMv8 translation table descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

AP[1] is valid only for a stage 1 translation that supports two VA ranges. It is RES0 for stage 1 translations that support only one VA range.

**NS, bit[5]** Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in the Secure or Non-secure address map, see [Control of Secure or Non-secure memory access on page D4-2070](#).

For memory accesses from Non-secure state, including all accesses in the EL2, or EL2&0, translation regime, this bit is RES0 and is ignored by the PE.

### AttrIndx[2:0], bits[4:2]

Stage 1 memory attributes index field, for the MAIR\_ELx, see [Stage 1 memory region type and Cacheability attributes on page D4-2090](#).

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-6341](#). For more information about these fields see [Other fields in the VMSAv8-64 translation table format descriptors on page D4-2093](#).

## Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 2 translation:

\* Bit[53] is RES0 before ARMv8.2.

\* RES0 in ARMv8.0.

□ Reserved for use by System MMU in ARMv8.0 and ARMv8.1.

For a stage 2 descriptor, the attributes are:

### PBHA, bits[62:59]

Page based hardware attributes bits.

These bits are IGNORED in descriptors at any level above level 3, and are IGNORED in level 3 descriptors in an implementation that does not include ARMv8.2-TTPBHA.

In an implementation that includes ARMv8.2-TTPBHA, VTCR\_EL2 has a control bit for each PBHA bit in the EL1&0 stage 2 translation tables. When the value of that control bit is 1, hardware can use that PBHA bit for IMPLEMENTATION DEFINED purposes.

For each PBHA bit, VTCR\_EL2.HWUnn controls whether descriptor bit[nn] can be used by hardware.

If ARMv8.2-TTPBHA is not implemented, then the control bits are RAZ/WI.

### XN[1:0], bits[54:53]

The Execute-never field. Determines whether the region is executable.

For more information, see *Access permissions for instruction execution* on page D4-2075.

In an implementation that does not support ARMv8.2-TTS2UXN, bit[53] is RES0.

### Contiguous, bit[52]

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see *The Contiguous bit* on page D4-2094.

**DBM, bit[51]** Dirty Bit Modifier, see *The dirty state bit* on page D4-2081.

**AF, bit[10]** The Access flag, see *The Access flag* on page D4-2081.

**SH, bits[9:8]** Shareability field, see *The stage 2 memory region attributes, EL1&0 translation regime* on page D4-2092.

### S2AP, bits[7:6]

Stage 2 data Access Permissions bits, see *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-2074.

### Note

In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

**MemAttr, bits[5:2]**

Stage 2 memory attributes, see [The stage 2 memory region attributes, EL1&0 translation regime on page D4-2092](#).

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-6341](#). For more information about these fields see [Other fields in the VMSAv8-64 translation table format descriptors on page D4-2093](#).

#### D4.3.4 Control of Secure or Non-secure memory access

As this section describes, the NS bit in the translation table entries:

- For accesses from Secure state, if the translation table entry was held in secure memory, determines whether the access is to Secure or Non-secure memory.
- Is ignored by:
  - Accesses from Non-secure state.
  - Accesses from Secure state if the translation table entry was held in Non-secure memory.

In the VMSAv8-64 translation table format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, that affects accesses at lower levels of lookup, see [Hierarchical control of Secure or Non-secure memory accesses](#).

The NS and NSTable bits are valid only for memory accesses from Secure state described by translation table descriptors that are fetched from Secure memory, and:

- In the translation table descriptors in a Non-secure translation table, the NS and NSTable bits are SBZ.
- Memory accesses from Non-secure state, including all accesses from EL2, ignore the values of these bits.

In the Secure translation regimes, for translation table descriptors that are fetched from Secure memory, the NS bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map, as follows:

**NS == 0** Access the Secure [PA](#) space.  
**NS == 1** Access the Non-secure [PA](#) space.

For Non-secure translation regimes, and for translation table descriptors fetched from Non-secure memory, the corresponding bit is RES0 and is ignored by the PE. The access is made to Non-secure memory, regardless of the value of the bit.

#### Hierarchical control of Secure or Non-secure memory accesses

For VMSAv8-64 table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

**NSTable == 0** The defined table address is in the Secure [PA](#) space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

**NSTable == 1** The defined table address is in the Non-secure [PA](#) space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:

- The value of the NS bit in any block or page descriptor is ignored. The block or page address refers to Non-secure memory.
- The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if it is read from Non-secure memory. That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see [Global and process-specific translation table entries on page D4-2116](#).

The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore a change to NSTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

## D4.4 Memory access control

The access control fields in the translation table descriptors determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- [About access permissions.](#)
- [About the PAN bit on page D4-2072.](#)
- [About the UAO bit on page D4-2072.](#)
- [Data access permission controls on page D4-2073.](#)
- [Access permissions for instruction execution on page D4-2075.](#)
- [The Access flag on page D4-2081.](#)
- [The dirty state bit on page D4-2081.](#)
- [Software management of the Access flag on page D4-2081.](#)
- [Hardware management of the Access flag and dirty state on page D4-2081.](#)
- [Ordering of hardware updates to the translation tables on page D4-2087.](#)
- [Restriction on memory types for hardware updates on page tables on page D4-2088.](#)
- [Use of the Contiguous bit with hardware updates of the translation table entries on page D4-2089.](#)

### ———— Note ————

This section describes the access controls for each of the translation regimes, and for each stage of translation in the Non-secure EL1&0 translation regime.

A translation applies to memory accesses from either:

- Only a single Exception level, for example the EL3 translation regime.
- EL0 and one higher Exception level, for example the EL1&0 translation regime.

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of the target memory region. These fields can be classified as address map control, access control, and region attribute fields. [Control of Secure or Non-secure memory access on page D4-2070](#) describes the address map control, and [Memory region attributes on page D4-2090](#) describes the other fields.

### D4.4.1 About access permissions

The translation table descriptors include fields that define access permissions for data accesses and for instruction fetches. This section introduces those fields. In addition:

- System register controls can prevent execution from writable locations, see [Preventing execution from writable locations on page D4-2080.](#)
- For the effect of disabling a stage of address translation on the access permissions see [The effects of disabling a stage of address translation on page D4-2053.](#)
- From ARMv8.1, the `PSTATE.PAN` bit can affect the access permissions for privileged data accesses, see [About the PAN bit on page D4-2072.](#)
- From ARMv8.2, the `PSTATE.UAO` bit can affect the access permissions for unprivileged instructions, see [About the UAO bit on page D4-2072.](#)

### ———— Note ————

This section gives a general description of memory access permissions. In an implementation that includes EL2, software executing at EL1 in Non-secure state can see only the access permissions defined by the Non-secure EL1&0 stage 1 translations. However, software executing at EL2 can modify these permissions. This modification is invisible to the Non-secure software executing at EL1 or EL0.

The access permission bits control access to the corresponding memory region. The VMSAv8-64 translation table format:

- In stage 1 translations, uses AP[2:1] to define the data access permissions, see [The AP\[2:1\] data access permissions, for stage 1 translations on page D4-2073](#).

———— **Note** ————

The description of the access permission field as AP[2:1] is for consistency with the VMSAv8-32 Short-descriptor translation table format, see [The VMSAv8-32 Short-descriptor translation table format on page G4-4576](#). The VMSAv8-64 translation table format does not define an AP[0] bit.

- In stage 2 translations, uses S2AP[1:0] to define the data access permissions, see [The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-2074](#).
- Uses the UXN, XN and PXN fields to define access controls for instruction fetches, see [Access permissions for instruction execution on page D4-2075](#).

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation.

———— **Note** ————

In an implementation that includes EL2, each stage of the translation of a memory access made using the Non-secure EL1&0 translation regime has its own, independent, permission check.

#### D4.4.2 About the PAN bit

When the value of `PSTATE.PAN` is 1, any privileged data access from EL1 or EL2 to a virtual memory address that is accessible at EL0 generates a Permission fault.

When the value of `PSTATE.PAN` is 0, the translation system is the same as in ARMv8.0.

A corresponding PAN bit is added to `SPSR_EL1`, `SPSR_EL2`, and `SPSR_EL3` for exception returns, and `DSPSR_EL0` for entry to or exit from Debug state.

A new SPAN bit is added to `SCTLR_EL1` and `SCTLR_EL2`, and applies when `HCR_EL2.{E2H, TGE} == {1, 1}`. The bit is used to control whether the PAN bit is set on an exception to EL1 or EL2.

The PAN bit has no effect on:

- Data Cache instructions other than DC ZVA.
- Address translation instructions, other than `ATS1E1RP` and `ATS1E1WP` when [ARMv8.2-ATS1E1](#) is implemented.
- Unprivileged instructions, `LDTR`, `LDTRB`, `LDTRH`, `LDTRSB`, `LDTRSH`, `LDTRSW`, `STTR`, `STTRB`, and `STTRH`, unless `HCR_EL2.{E2H, TGE} == {1, 0}`.
- Instruction accesses.

If access is disabled, then the access will give rise to a stage 1 Permission fault.

On an exception that is taken from AArch64 to AArch64, `PSTATE.PAN` is copied to `SPSR_ELx.PAN`.

On an exception return from AArch64:

- `SPSR_ELx.PAN` is copied to `PSTATE.PAN`, when the target Exception level is in AArch64.
- `SPSR_ELx.PAN` is copied to `CPSR.PAN`, when the target Exception level is in AArch32.

#### D4.4.3 About the UAO bit

When the value of `PSTATE.UAO` is 1, and when executed at EL1 or at EL2 with `HCR_EL2.{E2H, TGE} == {1, 1}`, the memory accesses made by the Load/Store unprivileged instructions behave as if they were made by the Load/Store register instructions. See [Load/Store unprivileged on page C3-164](#) and [Load/Store register on page C3-160](#).

When ARMv8.2-UAO is implemented and PSTATE.UAO is 0, it has no effect on the described behavior of any Load/Store unprivileged instruction.

A corresponding UAO bit is added to SPSR\_EL1, SPSR\_EL2, and SPSR\_EL3 for exception returns, and DSPSR\_EL0 for entry to or exit from Debug state.

On an exception that is taken from AArch64 to AArch64, PSTATE.UAO is copied to SPSR\_ELx.UAO and then set to 0.

On an exception that is taken from AArch32 to AArch64:

- PSTATE.UAO is set to 0.
- SPSR\_ELx.UAO is set to 0.

On an exception return from AArch64 to AArch64, SPSR\_ELx.UAO is copied to PSTATE.UAO.

#### D4.4.4 Data access permission controls

The following subsections describe the data access permission controls:

- *The AP[2:1] data access permissions, for stage 1 translations.*
- *The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-2074.*
- *Hierarchical control of data access permissions on page D4-2074.*

##### The AP[2:1] data access permissions, for stage 1 translations

In VMSAv8-64, for a translation regime that applies to both EL0 and a higher Exception level, the AP[2:1] bits control the stage 1 data access permissions, and:

**AP[2]** Selects between read-only and read/write access.

**AP[1]** Selects between Application level (EL0) control and the higher Exception level control.

This provides four permission settings for data accesses:

- Read-only at all levels.
- Read/write at all levels.
- Read-only at the higher Exception level, no access by software executing at EL0.
- Read/write at the higher Exception level, no access by software executing at EL0.

##### ————— Note —————

In an implementation that does not include [ARMv8.1-VHE](#), the only translation regime that applies to EL0 and a higher Exception level is the EL1&0 translation regime. In an implementation that includes [ARMv8.1-VHE](#), the EL2&0 translation regime applies to both Non-secure EL0 and EL2 when the value of [HCR\\_EL2](#).{E2H, TGE} is {1, 1}.

For translation regimes that apply only to accesses from a single Exception level, AP[2] determines the stage 1 data access permissions, and AP[1] is RES1, meaning it is ignored by hardware and is treated as if it is 1.

[Table D4-29](#) shows the meaning of the AP[2:1] field for stage 1 of a translation regime that applies to both EL0 and a higher Exception level. In this table, an entry of None indicates that any access from that Exception level faults.

**Table D4-29 Data access permissions for stage 1 translations that applies to EL0 and a higher Exception level**

AP[2:1]	Access from higher Exception level	Access from EL0
00	Read/write	None
01	Read/write	Read/write
10	Read-only	None
11	Read-only	Read-only

For the Non-secure EL1&0 translation regime:

- The stage 2 translation also defines data access permissions, see [The S2AP data access permissions, Non-secure EL1&0 translation regime](#).
- When both stages of translation are enabled, [Combining the stage 1 and stage 2 data access permissions on page D4-2095](#) describes how these permissions are combined.

Table D4-30 shows the effect of the AP[2] field for stage 1 of a translation regime that applies to only a single Exception level.

**Table D4-30 Data access permissions for stage 1 translations that apply to only a single Exception level**

AP[2]	Access permission
0	Read/write
1	Read-only

### The S2AP data access permissions, Non-secure EL1&0 translation regime

In the Non-secure EL1&0 translation regime, when stage 2 address translation is enabled, the S2AP field in the stage 2 translation table descriptors define the data access permissions as Table D4-31 shows. In this table, an entry of None indicates that any access generates a Permission fault.

**Table D4-31 Data access permissions for stage 2 of the Non-secure EL1&0 translation regime**

S2AP	Access from Non-secure EL1 or Non-secure EL0
00	None
01	Read-only
10	Write-only
11	Read/write

The S2AP access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined by AP[2:1], see [Combining the stage 1 and stage 2 data access permissions on page D4-2095](#).

[Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime on page D4-2095](#) gives more information about the use of the stage 1 and stage 2 access permissions in an implementation of virtualization.

### Hierarchical control of data access permissions

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the data access permissions.

#### ————— Note —————

Similar hierarchical controls apply to instruction fetching, see [Hierarchical control of instruction fetching on page D4-2079](#).

However, in an implementation that includes [ARMv8.1-HPD](#), when the value of a TCR\_ELx.HPD{0} field is 1, or the value of the TCR\_ELx.HPD1 field is 1, the hierarchical control of data access permissions is disabled for the translation stage controlled by that TCR\_ELx, and the information in this subsection does not apply.

The restrictions apply only to subsequent levels of lookup for the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table D4-32 shows. As stated in the table footnote, for a translation regime that applies to only a single Exception level, APTable[0] is RES0, meaning it is ignored by the hardware.

**Table D4-32 Effect of APTable[1:0] on subsequent levels of lookup**

APTable[1:0]	Effect
00	No effect on permissions in subsequent levels of lookup.
01 <sup>a</sup>	Access at EL0 not permitted, regardless of permissions in subsequent levels of lookup.
10	Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup.
11 <sup>a</sup>	Regardless of permissions in subsequent levels of lookup: <ul style="list-style-type: none"> <li>• Write access not permitted, at any Exception level.</li> <li>• Read access not permitted at EL0.</li> </ul>

a. Not valid any translation regime that applies to only a single Exception level. In the translation tables for such a regime, APTable[0] is RES0.

———— **Note** ————

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The VMSAv8-64 provides APTable[1:0] control only for stage 1 translations. The corresponding bits are RES0 in the stage 2 translation table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

## D4.4.5 Access permissions for instruction execution

Execute-never controls determine whether instructions can be executed from a memory region. These controls are:

### UXN, Unprivileged execute-never

Descriptor bit[54], defined as UXN only for stage 1 of any translation regime that applies to EL0 and a higher Exception level.

### XN, Execute-never

Descriptor bit[54], defined as XN for:

- Stage 1 of any translation regime that applies to only a single Exception level.
- Stage 2 of the Non-secure EL1&0 translation regime when ARMv8.2-TTS2UXN is not implemented.

———— **Note** ————

XN[1:0], Execute-never, for stage 2 control describes the stage 2 control when ARMv8.2-TTS2UXN is implemented.

A value of 0 indicates that this control permits execution.

### PXN, Privileged execute-never

Descriptor bit[53], used only for stage 1 of any translation regime that applies to EL0 and a higher Exception level:

- For stage 1 of a translation regime that applies to only a single Exception level the descriptors define a PXN field that is RES0, meaning it is ignored by hardware.

#### Note

For stage 2 of the Non-secure EL1&0 translation regime in an implementation where ARMv8.2-TTS2UXN is not supported, descriptor bit[53] is RES0, meaning it is ignored by hardware.

A value of 0 indicates that this control permits execution.

#### XN[1:0], Execute-never, for stage 2 control

Descriptor bits[54:53], defined as XN[1:0] for:

- Stage 2 of the Non-secure EL1&0 translation regime in an implementation where ARMv8.2-TTS2UXN is supported.

Table D4-33 shows the operation of this control.

**Table D4-33 XN[1:0] stage 2 access permissions model**

XN[1]	XN[0]	Access
0	0	The stage 2 control permits execution at EL1 and EL0
0	1	The stage 2 control does not permit execution at EL1, but permits execution at EL0
1	0	The stage 2 control does not permit execution at EL1 or EL0
1	1	The stage 2 control permits execution at EL1, but does not permit execution at EL0

#### Note

In an implementation that does not include ARMv8.1-VHE, the only translation regime that applies to EL0 and a higher Exception level is the EL1&0 translation regime. In an implementation that includes ARMv8.1-VHE:

- When the value of HCR\_EL2.E2H is 1, TCR\_EL2 controls the EL2&0 translation regime, and this regime:
  - Supports two VA ranges, corresponding to TTBR0\_EL2 and TTBR1\_EL2.
  - Always supports both UXN and PXN fields.
- Memory accesses from Non-secure EL0 are translated using the EL2&0 translation regime only when the value of HCR\_EL2.{E2H, TGE} is {1, 1}.

Table D4-33 shows the operation of the stage 2 XN[1:0] control, and for each single-bit execute-never field a value of 1 indicates that instructions cannot be executed from the target memory region. In addition:

- For a translation regime that applies to EL0 and a higher Exception level, if the value of the AP[2:1] bits is 0b01, permitting write access from EL0, then the PXN field is treated as if it has the value 1, regardless of its actual value.
- In a translation regime with two stages of translation, a region is execute-never if execution is not permitted by the value of the applicable execute-never field in one or both of:
  - The stage 1 translation table descriptor.
  - The stage 2 translation table descriptor.
- For each translation regime, if the value of the corresponding SCTLR\_ELx.WXN field is 1 then any memory region that is writable is treated as XN, regardless of the value of the corresponding UXN, XN, or PXN field. For more information, see *Preventing execution from writable locations* on page D4-2080.
- The SCR\_EL3.SIF bit prevents execution in Secure state of any instruction fetched from Non-secure memory, see *Restriction on Secure instruction fetch* on page D4-2080.

The execute-never controls apply to speculative instruction fetching, meaning speculative instruction fetch from a memory region that is execute-never at the current Exception level is prohibited.

---

**Note**

---

- Although the execute-never controls apply to speculative fetching, on a speculative instruction fetch from an execute-never location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an execute-never location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.
- The software that defines a translation table must mark any region of memory that is read-sensitive as execute-never, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as execute-never. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.
- When no stage of address translation for the translation regime is enabled, memory regions cannot have UXN, XN, or PXN attributes assigned. *Behavior of instruction fetches when all associated stages of translation are disabled on page D4-2054* describes how disabling all stages of address translation affects instruction fetching.

The following subsections describe the data access permission controls:

- *Stage 1 instruction access and execution permissions.*
- *Stage 2 instruction execution permissions on page D4-2079.*
- *Hierarchical control of instruction fetching on page D4-2079.*
- *Preventing execution from writable locations on page D4-2080.*
- *Restriction on Secure instruction fetch on page D4-2080.*

**Stage 1 instruction access and execution permissions**

Table D4-34 and Table D4-35 on page D4-2078 include the AP[2:1] read and write permissions shown in Table D4-29 on page D4-2073 and Table D4-30 on page D4-2074. These permissions are shown as:

- R** . Indicates Read permission granted.  
**W** . Indicates Write permission granted.

Table D4-34 shows the stage 1 access permissions for instruction execution when using a translation regime that applies to EL0 and a higher Exception level.

**Table D4-34 Stage 1 access permissions for instruction execution for a translation regime that applies to EL0 and a higher Exception level**

UXN	PXN	AP[2:1]	SCTLR_ELx.WXN <sup>a</sup>	Access from higher Exception level	Access from EL0
0	0	00	0	R, W, Executable	Executable
			1	R, W, Not executable <sup>b</sup>	Executable
	01	0	0	R, W, Not executable <sup>c</sup>	R, W, Executable
			1	R, W, Not executable	R, W, Not executable <sup>d</sup>
	10	x	x	R, Executable	Executable
	11	x	x	R, Executable	R, Executable

**Table D4-34 Stage 1 access permissions for instruction execution for a translation regime that applies to EL0 and a higher Exception level (continued)**

UXN	PXN	AP[2:1]	SCTLR_ELx.WXN <sup>a</sup>	Access from higher Exception level	Access from EL0
0	1	00	x	R, W, Not executable	Executable
		01	0	R, W, Not executable	R, W, Executable
			1	R, W, Not executable	R, W, Not executable <sup>d</sup>
		10	x	R, Not executable	Executable
		11	x	R, Not executable	R, Executable
1	0	00	0	R, W, Executable	Not executable
			1	R, W, Not executable <sup>b</sup>	Not executable
		01	x	R, W, Not executable <sup>c</sup>	R, W, Not executable
		10	x	R, Executable	Not executable
		11	x	R, Executable	R, Not executable
	1	00	x	R, W, Not executable	Not executable
		01	x	R, W, Not executable	R, W, Not executable
		10	x	R, Not executable	Not executable
		11	x	R, Not executable	R, Not executable

a. Where ELx is the higher Exception level to which the translation regime applies.

b. Not executable because of SCTLR\_ELx.WXN control, because region is writable at ELx.

c. Not executable, because AArch64 execution treats all regions writable at EL0 as being PXN.

d. Not executable because of SCTLR\_ELx.WXN control, because region is writable at EL0.

Table D4-35 shows the stage 1 access permissions for instruction execution when using a translation regime that applies to only a single Exception level.

**Table D4-35 Access permissions for instruction execution for a translation regime that applies to only a single Exception level**

XN	AP[2]	SCTLR_ELx.WXN <sup>a</sup>	Access permission
0	0	0	R, W, Executable
		1	R, W, Not executable <sup>b</sup>
	1	x	R, Executable
1	0	x	R, W, Not executable
	1	x	R, Not executable

a. Where ELx is the higher Exception level to which the translation regime applies.

b. Not executable because of the SCTLR\_ELx.WXN control, because region is writable at ELx.

#### ———— Note ————

The Access permissions for an AArch64 translation regime that applies to only a single Exception level are consistent with the following fields in the translation table entries being treated as shown:

- AP treated as RES1.

- [APTable\[0\]](#) treated as RES0.
- [PXN](#) treated as RES0.
- [PXNTable](#) treated as RES0.

## Stage 2 instruction execution permissions

For the Non-secure EL1&0 stage 2 translation, the XN fields in the stage 2 translation table descriptors control the execution permission, and this control is completely independent of the S2AP access permissions.

**Table D4-36 Access permissions for instruction execution for stage 2 of the Non-secure EL1&0 translation regime**

XN	Access from Non-secure EL1or Non-secure EL0
0	Executable
1	Not executable

The stage 2 XN access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined at stage 1 of the translation, see [Combining the stage 1 and stage 2 instruction execution permissions on page D4-2096](#).

## Hierarchical control of instruction fetching

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the instruction fetching controls.

### Note

Similar hierarchical controls apply to data accesses, see [Hierarchical control of data access permissions on page D4-2074](#).

However, in an implementation that includes [ARMv8.1-HPD](#), when the value of a [TCR\\_ELx.HPD{0}](#) field is 1, or the value of the [TCR\\_ELx.HPD1](#) field is 1, the hierarchical control of instruction fetching is disabled for the translation stage controlled by that [TCR\\_ELx](#), and the information in this subsection does not apply.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- [UXNTable](#) or [XNTable](#) restricts the execute-never control:
  - When the value of the [XNTable](#) bit is 1, the [XN](#) bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of the [UXNTable](#) bit is 1, the [UXN](#) bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of a [UXNTable](#) or [XNTable](#) bit is 0 the bit has no effect.
- For a translation regime that applies to EL0 and a higher Exception level, [PXNTable](#) restricts the [PXN](#) control:
  - When the value of [PXNTable](#) is 1, the [PXN](#) bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When the value of [PXNTable](#) is 0 it has no effect.

---

**Note**

---

The [UXNTable](#), [XNTable](#), and [PXNTable](#) settings are combined with the [UXN](#), [XN](#), and [PXN](#) bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

---

The [UXNTable](#), [XNTable](#), and [PXNTable](#) controls are provided only for stage 1 translations. The corresponding bits are RES0 in the stage 2 translation table descriptors.

The effect of [UXNTable](#), [XNTable](#), or [PXNTable](#) applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to [UXNTable](#), [XNTable](#), or [PXNTable](#) requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

### Preventing execution from writable locations

ARMv8 provides control bits that, when corresponding stage 1 address translation is enabled, force writable memory to be treated as [UXN](#), [PXN](#), or [XN](#), regardless of the value of the [UXN](#), [PXN](#), or [XN](#) bit:

- For a translation regime that applies to EL0 and a higher Exception value, when the value of the applicable [SCTLR\\_ELx.WXN](#) field is 1:
  - All regions that are writable from EL0 at stage 1 of the address translation are treated as [UXN](#).
  - All regions that are writable from EL1 at stage 1 of the address translation are treated as [PXN](#).
- For a translation regime that applies to only a single Exception level, when the value of the applicable [SCTLR\\_ELx.WXN](#) field is 1, all regions that are writable at stage 1 of the address translation are treated as [XN](#).

---

**Note**

---

- The [SCTLR\\_ELx.WXN](#) controls are intended to be used in systems with very high security requirements.
  - Setting a [WXN](#) field to 1 changes the interpretation of the translation table entry, overriding a zero value of a [UXN](#), [XN](#), or [PXN](#) field. It does not cause any change to the translation table entry.
- 

For any given virtual machine, ARM expects [WXN](#) to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular [VMID](#) reflect the effect of the values of these fields. This means that any change of these fields without a corresponding change of [VMID](#) might require synchronization and TLB invalidation, as described in [TLB maintenance requirements and the TLB maintenance instructions](#) on page D4-2119.

### Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, [SCR\\_EL3.SIF](#). When the value of this bit is 1, and execution is using the EL3 translation regime or the Secure EL1&0 translation regime, any attempt to execute an instruction fetched from Non-secure physical memory causes a Permission fault. TLB entries might reflect the value of this bit, and therefore any change to the value of this bit requires synchronization and TLB invalidation, as described in [TLB maintenance requirements and the TLB maintenance instructions](#) on page D4-2119.

#### D4.4.6 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0.

The AF bit in the translation table descriptors is the Access flag.

In ARMv8.0, the Access flag is managed by software as described in [Software management of the Access flag](#).

From ARMv8.1, the Access flag can be managed by hardware as described in [Hardware management of the Access flag on page D4-2082](#).

---

**Note**

The support for hardware management of the Access flag is in AArch64 state only.

---

#### D4.4.7 The dirty state bit

The dirty state bit indicates whether a page or section of memory is modified.

The DBM bit in the translation table descriptors is the dirty state bit.

The dirty state bit can be managed by hardware as described in [Hardware management of dirty state on page D4-2083](#).

#### D4.4.8 Software management of the Access flag

ARMv8.0 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a translation table descriptor entry for which the value of Access flag is 0.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

---

**Note**

If a system incorporates components that can autonomously update translation table entries that are shared with the ARM PE, then the software must be aware of the possibility that such components can update the access flag autonomously.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

---

#### D4.4.9 Hardware management of the Access flag and dirty state

ARMv8.1 introduces the following optional features that perform hardware updates to the translation tables:

- [Hardware management of the Access flag on page D4-2082](#).
- [Hardware management of dirty state on page D4-2083](#).

The support for hardware management of the Access flag and dirty state is identified by the feature [ARMv8.1-TTHM](#).

When the hardware management of the Access flag is enabled, in situations where, without this feature, an Access flag fault would be generated, the hardware instead performs an atomic read-modify-write of the appropriate translation table descriptor to update the Access flag from 0 to 1.

When the hardware management of dirty state is enabled, if the Block or Page descriptor in a translation table indicates that a data access does not have write permission, then in situations where, without this feature, a data access would generate a Permission fault only because of this lack of write permission, the hardware checks the

value of the DBM field in the Block or Page descriptor. If this field is 1, then instead of generating a Permission fault, the hardware performs an atomic read-modify-write of the translation table descriptor, to change the value of the bit that prohibits the write access.

## Hardware management of the Access flag

Hardware management of the Access flag is enabled, for the corresponding stage of address translation, by the following configuration fields:

### For stage 1 translations

- [TCR\\_EL1.HA](#).
- [TCR\\_EL2.HA](#).
- [TCR\\_EL3.HA](#).

### For stage 2 translations

- [VTCR\\_EL2.HA](#).

Implementations are not required to support the hardware management of the Access flag. If [ARMv8.1-TTHM](#) is not supported, then the HA bit in [TCR\\_EL1](#), [TCR\\_EL2](#), [TCR\\_EL3](#), and [VTCR\\_EL2](#) is RES0.

When the value of a configuration bit, HA, is 1, then when a memory access is made using a translation table Block or Page descriptor from the corresponding stage of address translation:

- The PE sets the value of the Access flag to 1 in the translation table descriptor in memory, in a coherent manner, by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:
  - The descriptor does not generate a Permission fault or an Alignment fault based on the memory type.
  - If the hardware update mechanism was disabled or not implemented, the access would have generated an Access flag fault.

When the PE updates the Access flag in this way no Access flag fault is generated.

- It is CONSTRAINED UNPREDICTABLE whether the PE sets the value of the Access flag in the translation table entry in memory to 1, in a coherent manner, by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true.
  - The descriptor generates a Permission fault or an Alignment fault based on the memory type.
  - If the hardware update mechanism was disabled or not implemented, the access would have generated an Access flag fault.

This means that the value of the Access flag becomes UNKNOWN if the above conditions are all true.

The Access flag might be set to 1 as a result of speculative accesses by the PE.

### ———— Note ————

A consequence of the architectural rules for translation table accesses is that the architecture requires that for any translation to which an architecturally executed memory access occurs, the Access flag is set to 1, except as indicated in [Using break-before-make when updating translation table entries on page D4-2120](#). However, because the architecture permits speculative accesses, the Access flag is permitted to be set to 1, even if there is no architecturally executed memory accesses by the processor.

When hardware updating of the Access flag is enabled, each stage of translation is treated independently. This means that a single memory access can cause a hardware update to either or both:

- The stage 1 Access flag.
- The stage 2 Access flag.

---

**Note**

---

Since speculative accesses are permitted to update the Access flags, it is permissible for:

- The stage 1 Access flag for a translation of a virtual address to be updated in situations where the stage 2 translation of the associated intermediate physical address that is returned by the stage 1 of the virtual address does not permit access.
  - The stage 2 Access flag for a translation of an intermediate physical address to be updated in situations where the stage 1 translation of the associated virtual address which returned that intermediate physical address does not permit access.
- 

An address translation instruction for an address is permitted, but not required, to set the Access flag in the translation table entries for that address. Correspondingly, it is IMPLEMENTATION DEFINED whether such an instruction can generate a Data Abort if the Access flag for a stage of translation is updated to be set.

When hardware updates of the Access flag are enabled for a stage of translation an address translation instruction that uses that stage of translation will not report that the address will give rise to an Access flag fault in the PAR, and the result in PAR will be as if the value of the Access flag in the translation table entries for that address was 1.

### Hardware management of dirty state

The hardware management of dirty state mechanism can only be enabled if hardware management of the Access flag is enabled. For information on the hardware management of the Access flag, see [Hardware management of the Access flag on page D4-2082](#).

---

**Note**

---

The hardware management of dirty state mechanism uses:

- In a stage 1 translation table access, the AP[2] bit in conjunction with the DBM bit in the translation table descriptors.
  - In a stage 2 translation table access, the S2AP[1] bit in conjunction with the DBM bit in the translation table descriptors.
- 

Hardware management of dirty state is enabled, for the corresponding stage of address translation, by the following configuration fields:

**For stage 1 translations**

- [TCR\\_EL1.HD](#).
- [TCR\\_EL2.HD](#).
- [TCR\\_EL3.HD](#).

**For stage 2 translations**

- [VTCR\\_EL2.HD](#).

Implementations are not required to support the dirty state mechanism. If this mechanism is not supported, then the HD bit in [TCR\\_EL1](#), [TCR\\_EL2](#), [TCR\\_EL3](#), and [VTCR\\_EL2](#) is RES0.

When hardware management of dirty state is enabled, and a memory access is made using a translation table Block or Page descriptor:

- For a stage 1 address translation, if the value of the TCR\_ELx.HD field corresponding to the address translation is 1, then the PE sets AP[2] to 0 in the translation descriptor in memory, in a coherent manner by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:
  - The value of the DBM field in the descriptor is 1.
  - If the hardware update mechanism was disabled or not implemented, the access using this descriptor would have generated a Permission fault only because the value of the AP[2] field is 1, indicating that the access does not have write permission.

When the PE updates AP[2] in this way no Permission fault is generated because of the value of the AP[2] field.

- For a stage 2 address translation, if the value of the VTCR\_EL2.HD field is 1, then the PE sets S2AP[1] to 1 in the translation descriptor in memory, in a coherent manner by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:
  - The value of the DBM field in the descriptor is 1.
  - If the hardware update mechanism was disabled or not implemented, the access using this descriptor would have generated a Permission fault only because the value of the S2AP[1] field is 0, indicating that the access does not have write permission.

When the PE updates S2AP[1] in this way no Permission fault is generated because of the value of the S2AP[1] field.

---

**Note**

The PE that does the atomic update of the translation table descriptor is expected to ensure that any cached copy of that translation table descriptor for that PE is similarly updated, or removed from the TLB, so that multiple writes from the same thread on the same PE do not lead to multiple updates to the table. This is only a performance expectation.

---

If, for a write access, the PE finds that a cached copy of the descriptor in a TLB had the DBM bit set to 1 and the AP[2] or S2AP[1] bit set to the value that forbids writes, then the PE must check that the cached copy is not stale with regard to the descriptor entry in memory, and if necessary perform an atomic read-modify-write update of the descriptor in memory. This applies if the cached copy of the descriptor in a TLB is either:

- A stage 1 descriptor in which DBM has the value 1 and AP[2] has the value 1.
- A stage 2 descriptor in which DBM has the value 1 and S2AP[1] has the value 0.

---

**Note**

ARM expects that, in many implementations, any atomic update of a translation table entry required by the dirty state management mechanism will cause a translation table walk.

---

For the hardware updating of the AP[2] and S2AP[1] bits, each translation stage is treated independently. This means a single memory access can update either or both of:

- The stage 1 AP[2] bit.
- The stage 2 S2AP[1] bit.

The architecture does not permit updates to AP[2] and S2AP[1] by the hardware management of dirty state mechanism to occur as a result of speculative accesses by the PE that are not performed architecturally, except that:

- A non-speculative access that passes its stage 1 permissions check can update AP[2] and subsequently encounter a stage 2 fault.

---

**Note**

This update of AP[2] is permitted even if the transaction subsequently encounters a stage 2 Translation fault or a Permission fault. This avoids a need to update both AP[2] and S2AP[1] as a single atomic update.

- 
- A non-speculative access that generates an Alignment fault only because the memory type accessed is Device memory by a stage of translation can update AP[2] or S2AP[1] of that stage of translation if the memory access would have updated that translation table bit had the memory access not generated the Alignment fault.
  - If the stage 2 hardware management of dirty state mechanism is enabled, the S2AP[1] field of a stage 2 translation table entry that is translating a stage 1 translation table without generating a stage 2 MMU fault:
    - Is updated from 0 to 1 as a result of a speculative update of the Access flag in an entry of that stage 1 translation table.
    - Is permitted to be updated speculatively from 0 to 1 as a result of performing a translation table walk using that stage1 translation table, even if the entry in the stage 1 translation table is not updated.

---

**Note**

---

This applies even if the stage 1 translation table contains entries that are not the final level entries and therefore would not be updated. This relaxation avoids the hardware complexity of having to detect whether the stage 1 entry is a final level entry before deciding to set the stage 2 dirty state information.

---

- If an instruction that generates more than one single-copy atomic memory access has a fault on some, but not all, of those memory accesses, then AP[2] and S2AP[1] bits associated with accesses from that instruction, which do not fault are permitted to be updated if the associated hardware update of dirty state mechanism is enabled.

For a Block or Page translation table descriptor for which the AF bit is 0, the DBM bit is 1, and either the value of the stage 1 AP[2] bit is 1 or the value of the stage 2 S2AP[1] bit is 0, both AF can be set to 1, and either AP[2] set to 0 or S2AP[1] set to 1, in a single atomic read-modify-write operation, as a result of an attempted write to a memory location that uses the translation table entry.

### Implications of enabling the dirty state management mechanism

This subsection describes behaviors that result from having the dirty state management mechanism enabled for a particular stage of address translation.

For the final level of lookup in a stage 1 translation:

#### In the EL3 translation regime

The OA of the lookup is treated as writable if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2] is 1.
- In the descriptor for every higher level of lookup, the value of APTable[1] is 0.

In this case, if the value of SCTLRL\_EL3.WXN is 1 then the OA is treated as Execute-never.

#### In the EL2 or EL2&0 translation regime, when the value of HCR\_EL2.{E2H, TGE} is not {1, 1}

---

**Note**

---

When the value of HCR\_EL2.E2H is 1, [TCR\\_EL2](#) controls the EL2&0 translation regime, and otherwise it controls the EL2 translation regime.

---

The OA of the lookup is treated as writable if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2] is 1.
- In the descriptor for every higher level of lookup the value of APTable[1] is 0.

In this the value of [SCTLRL\\_EL2](#).WXN is 1 then the OA is treated as Execute-never.

In addition, if the value of HCR\_EL2.E2H is 1, the OA is treated as Privileged execute-never if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
- In the descriptor for every higher level of lookup, the value of APTable[1:0] is 0b00.

---

**Note**

---

When the value of HCR\_EL2.{E2H, TGE} is not {1, 1}, memory accesses from EL0 do not use the EL2, or EL2&0, translation regime.

---

**In the EL2&0 translation regime, when the value of HCR\_EL2.{E2H, TGE} is {1, 1}**

The OA of the lookup is treated as writable at EL2 and EL0, Privileged execute-never, if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
- In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b00.

In this case, if the value of SCTLR\_EL2.WXN is 1 then the OA is also treated as Unprivileged execute-never.

The OA of the lookup is treated as writable at EL2 but not writable at EL0 if either:

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b10.
  - In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b0x.

In this case, if the value of SCTLR\_EL2.WXN is 1 then the OA is treated as Privileged execute-never.

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
  - In at least one of the descriptors for higher levels of lookup the value of APTable[1:0] is 0b01.

In this case, if the value of SCTLR\_EL2.WXN is 1 then the OA is treated as Privileged execute-never.

**In the EL1&0 translation regime**

The OA of the lookup is treated as writable at EL1 and EL0, Privileged execute-never, if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
- In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b00.

In this case, if the value of SCTLR\_EL1.WXN is 1 then the OA is treated as Unprivileged execute-never.

The OA of the lookup is treated as writable at EL1 but not writable at EL0 if either:

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
  - In at least one of the descriptors for higher levels of lookup the value of APTable[1:0] is 0b01.

In this case, if the value of SCTLR\_EL1.WXN is 1 then the OA is treated as Privileged execute-never.

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b10.
  - In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b0x.

In this case, if the value of SCTLR\_EL1.WXN is 1 then the OA is treated as Privileged execute-never.

The OA of a translation table entry where the DBM bit is 1, and the stage 1 AP[2] bit is 1 or the stage 2 S2AP[1] bit is 0, is treated as writable:

- For data cache invalidation instructions that require write permission, that is for the DC IVAC instruction.
- For address translation instructions that require write permission, that is for the AT S12E0W, AT S12E1W, AT S1E0W, AT S1E1W, AT S1E2W, and AT S1E3W instructions.

Cache invalidation and address translation instructions never cause the stage 1 AP[2] bit or the stage 2 S2AP[1] bit in the translation table entry to be updated.

For a Store-Exclusive instruction to a memory location for which the DBM bit is 1 and the stage 1 AP[2] bit is 1, if the Store-Exclusive fails because the Exclusives monitor is not in the exclusive state, it is IMPLEMENTATION DEFINED whether the AP[2] bit in the translation table is updated.

For a Store-Exclusive instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, if the Store-Exclusive fails because the Exclusives monitor is not in the Exclusive access state, it is IMPLEMENTATION DEFINED whether the S2AP[1] bit in the translation table is updated.

For a store to a memory location for which the DBM bit is 1, and the stage 1 AP[2] bit is 1, it is IMPLEMENTATION DEFINED whether the AP[2] bit in the translation table is updated:

- If the memory location generates a synchronous external abort on a write for a store to a memory location.
- If the memory location generates a watchpoint on a write.

For a store to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, it is IMPLEMENTATION DEFINED whether the S2AP[1] bit in the translation table is updated:

- If the memory location generates a synchronous external abort on a write for a store to a memory location.
- If the memory location generates a watchpoint on a write.

In the event of a PE setting the stage 1 AP[2] bit to 0, it is not required that all associated entries are removed from the TLBs of other PEs in the system.

In the event of a PE setting the stage 2 S2AP[1] bit to 1, it is not required that all associated entries are removed from the TLBs of other PEs in the system.

For the stage 2 translation tables, it is CONSTRAINED UNPREDICTABLE whether the stage 2 S2AP[1] entry is updated in response to a stage 1 translation table walk where the stage 1 translation system is configured to perform hardware updates to the Access flag or stage 1 AP[2] bit, but the values of the Access flag and AP[2] bit are such that a hardware update to the stage 1 translation table entry being accessed is not required.

In the event of a PE encountering a situation for a data write for which the DBM bit is 1 and the stage 1 AP[2] bit is 1 in a TLB, it is required that the hardware checks that the cached copy is not stale with regards to the translation table entry in memory and performs the atomic read-modify-write update with respect to table entry in memory.

In the event of a PE encountering a situation for a data write for which the DBM bit is 1 and stage 2 S2AP[1] bit is 0 in a TLB, it is required that the hardware checks that the cached copy is not stale with regards to the translation table entry in memory and performs the atomic read-modify-write update with respect to table entry in memory.

For a CAS or CASP instruction to a memory location for which the DBM bit is 1, and the stage 1 AP[2] bit is 1, if the compare fails, and the location is not updated, it is CONSTRAINED UNPREDICTABLE whether the AP[2] bit in the translation table is updated.

For a CAS or CASP instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, if the compare fails, and the location is not updated, it is CONSTRAINED UNPREDICTABLE whether the S2AP[1] bit in the translation table is updated.

For an atomic instruction to a memory location for which the DMB bit is 1, and the stage 2 S2AP[0:1] is 00, if the instruction generates a stage 2 Permission fault as a result of not having read permission, it is CONSTRAINED UNPREDICTABLE whether the S2AP[1] bit in the translation table is updated.

#### D4.4.10 Ordering of hardware updates to the translation tables

A hardware update to the translation table that is caused by a load or a store, including an atomic instruction, is guaranteed to be observed, to the extent required by the shareability attributes:

- Before a load or store, including an atomic instruction, to an arbitrary address, other than the address of the translation table entry, that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load or store.

- Before a load to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load.
- Before a store or atomic access to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry.
- Before a cache maintenance instruction to an arbitrary address appearing in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction that caused the update to the translation table entry and the subsequent cache maintenance instruction.

An update to the translation table that is caused by a load is not ordered with respect to the load itself.

An update to the translation table that is caused by a store or an atomic access is observed by all observers, to the extent required by the shareability attributes, before the store itself in the case that the store is to the same location as the translation table update.

An update to the translation table that is caused by a store or an atomic access is not ordered with respect to the store itself in the case that the store is not the same location as the translation table update.

#### D4.4.11 Restriction on memory types for hardware updates on page tables

Translation tables can be placed in Normal memory with any cacheability, but the hardware updates to the translation tables require an atomic update of memory. The properties of the atomicity can be met only by functionality outside the PE. Some system implementations might not implement this functionality for all regions of memory. This can apply to:

- Any type of memory in the system that does not support hardware cache coherency.
- Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does not support hardware cache coherency.

An implementation can choose which memory type is treated as Non-cacheable.

The memory types for which it is architecturally guaranteed that the hardware updates of the translation tables will be atomic are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

If the hardware updates of the translation tables are not atomic in regard to other agents that access memory, then performing a hardware update to such a location can have one or more of the following effects:

- The hardware update generates a Synchronous external abort, which is presented as an external abort on a translation table walk.
- The instruction generates a SError interrupt.
- The hardware update generates an Unsupported atomic hardware update MMU fault reported using the Fault status code of:

— `ESR_ELx.DFSC = 110001` for Data Aborts.

— `ESR_ELx.IFSC = 110001` for Instruction Aborts.

For the Non-secure EL1&0 translation regime, if atomic hardware update is not supported because of the memory type that is defined in the first stage of translation, or the second stage of translation is not enabled, then this exception is a first stage abort and is taken to EL1. Otherwise, the exception is a second stage abort and is taken to EL2.

The priority of this MMU fault for a stage of the translation is immediately before or immediately after the priority of a Permission fault generated by the same stage of translation as the stage of this MMU fault, as determined by an IMPLEMENTATION DEFINED choice.

- The hardware updates are performed, but there is no guarantee that the memory accesses were performed atomically in regard to other agents that access memory. In this case, the instruction might also generate a SError interrupt.

#### D4.4.12 Use of the Contiguous bit with hardware updates of the translation table entries

The hardware update of the Access flag, and the AP[2]/S2AP[1] bit only apply to a single translation table entry. An update to one of these bits in a translation table entry that also has the Contiguous bit set to 1 can give rise to translation table entries that have different Access flag, or different AP[2] and S2AP[1] bits within the members of a group of contiguous translation table entries.

This is acceptable under the architecture when using hardware updates of the translation table entries. In addition, an access or a write to a location translated by an entry that has the Contiguous bit set might not result in a hardware update of the Access flag or the AP[2]/S2AP[1] bit, if at least one entry in the set of contiguous translation table entries has the Access flag set to 1, or the AP[2]/S2AP[1] bit indicating that the entry is dirty.

##### ————— **Note** —————

- The provision of the Contiguous bit permits, but does not require, the hardware to hold a single entry in a TLB for the set of translation table entries in the group, and to have updated only one or more of the Access flags and the AP[2] bit or S2AP[1] bit for the single translation table entry that gave rise to the TLB entry.
- A consequence of this is that software must combine the Access flag values, and AP[2] or S2AP[1] values, across all translation table entries in a contiguous group to determine whether any of the entries have been accessed or written to.

---

For more information on the Contiguous bit, see [The Contiguous bit on page D4-2094](#).

## D4.5 Memory region attributes

The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent. This section also describes some additional translation table fields, that this manual groups with the memory region attributes.

In the EL1&0 translation regime, each enabled stage of address translation assigns memory region attributes, as described in this section. When both stages of translation are enabled, [Combining the stage 1 and stage 2 attributes](#), [Non-secure EL1&0 translation regime on page D4-2095](#) describes how the assignments from the two stages are combined.

---

### Note

In a virtualization implementation, a hypervisor, executing at EL2, might usefully:

- Reduce the permitted cacheability of a region.
- Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

---

The following sections describe these attributes:

- [The stage 1 memory region attributes](#).
- [The stage 2 memory region attributes, EL1&0 translation regime on page D4-2092](#).
- [Other fields in the VMSAv8-64 translation table format descriptors on page D4-2093](#).

---

### Note

- This section describes the memory region attributes for each of the translation regimes, and for each stage of translation in the Non-secure EL1&0 translation regime.
- A translation applies to memory accesses from either:
  - Only a single Exception level, for example the EL3 translation regime.
  - EL0 and one higher Exception level, for example the EL1&0 translation regime.
- In general, attribute assignment is simpler in a regime that applies to only a single Exception level, and in these regimes behavior is consistent with fields in the translation tables being treated as follows:
  - [AP\[1\]](#) is RES1, meaning the PE ignores the value of the bit and behaves as if it is 1.
  - [APTable\[0\]](#) is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
  - The [PXN](#) field is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
  - The [PXNTable](#) bit is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.

### D4.5.1 The stage 1 memory region attributes

The description of the memory region attributes in a translation descriptor divides into:

#### Memory type and Cacheability

These are described indirectly, by registers referenced by bits in the table descriptor. This is described as *remapping* the memory type and attribute description. [Stage 1 memory region type and Cacheability attributes](#) describes this encoding.

**Shareability** The SH[1:0] field in the translation table descriptor encodes shareability information. [Stage 1 Shareability attribute, for Normal memory on page D4-2091](#) describes this encoding.

#### Stage 1 memory region type and Cacheability attributes

In the VMSAv8-64 translation table format, the AttrIdx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field in the [MAIR\\_ELx](#) that specifies the attributes for the corresponding memory region. The required field is Attr<sub>n</sub>, where  $n = \text{AttrIdx}[2:0]$ . For more information about AttrIdx[2:0] see [Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors on page D4-2066](#)

---

**Note**

---

Each **MAIR\_ELx** is a 64-bit register that is architecturally mapped to a pair of AArch32 registers. See the **MAIR\_ELx** register descriptions for more information.

---

Each **MAIR\_ELx.Attrn** field defines, for the corresponding memory region:

- The memory type, Device or Normal.
- For Device memory, the Device memory type, one of:
  - Device-nGnRnE.
  - Device-nGnRE.
  - Device-nGRE.
  - Device-GRE.
- For Normal memory:
  - The inner and outer cacheability, Non-cacheable, Write-Through, or Write-Back
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is *Allocate* or *No Allocate*, and the Transient allocation hints, if supported.

For more information about the memory type and attributes, see *Memory types and attributes* on page B2-107 and *Cacheability, cache allocation hints, and cache transient hints* on page D3-1977.

### Stage 1 Shareability attribute, for Normal memory

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. [Table D4-37](#) shows the encoding of this field.

**Table D4-37 SH[1:0] field encoding for Normal memory, VMSAv8-64 translation table format**

SH[1:0]	Normal memory
00	Non-shareable
01	Reserved, CONSTRAINED UNPREDICTABLE <sup>a</sup>
10	Outer Shareable
11	Inner Shareable

a. See *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6133 for the permitted CONSTRAINED UNPREDICTABLE behavior.

---

**Note**

---

The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes

---

See *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D4-2097 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

## D4.5.2 The stage 2 memory region attributes, EL1&0 translation regime

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- [Stage 2 memory region type and Cacheability attributes](#) describes how the MemAttr[3:0] field defines these attributes.
- The SH[1:0] field in the translation table descriptor encodes shareability information. [Stage 2 Shareability attribute, for Normal memory on page D4-2093](#) describes this encoding.

The following sections describe how, when both stages of address translation are enabled, the memory region attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- [Combining the stage 1 and stage 2 memory type attributes on page D4-2096](#).
- [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D4-2097](#).
- [Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D4-2097](#).

### Stage 2 memory region type and Cacheability attributes

[Table D4-38](#) shows how MemAttr[3:2] gives a top-level definition of the memory type, and of the Outer cacheability of a Normal memory region.

**Table D4-38 VMSAv8-64 MemAttr[3:2] encoding, stage 2 translation**

MemAttr[3:2]	Memory type	Outer cacheability
00	Device. MemAttr[1:0] encodes the Device memory type.	Not applicable
01	Normal. MemAttr[1:0] encodes the Inner Cacheability.	Outer Non-cacheable
10		Outer Write-Through Cacheable
11		Outer Write-Back Cacheable

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2] == 0b00, indicating Device memory, [Table D4-39](#) shows the encoding of MemAttr[1:0].

**Table D4-39 MemAttr[1:0] encoding for Device memory**

MemAttr[1:0]	Meaning when MemAttr[3:2] == 0b00
00	Region is Device-nGnRnE memory
01	Region is Device-nGnRE memory
10	Region is Device-nGRE memory
11	Region is Device-GRE memory

- When MemAttr[3:2] != 0b00, indicating Normal memory, [Table D4-40](#) shows the encoding of MemAttr[1:0].

**Table D4-40 MemAttr[1:0] encoding for Normal memory**

MemAttr[1:0]	Meaning when MemAttr[3:2] != 0b00
00	Reserved, CONSTRAINED UNPREDICTABLE <sup>a</sup>

**Table D4-40 MemAttr[1:0] encoding for Normal memory (continued)**

MemAttr[1:0]	Meaning when MemAttr[3:2] != 0b00
01	Inner Non-cacheable
10	Inner Write-Through Cacheable
11	Inner Write-Back Cacheable

- a. See *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6133 for the permitted CONSTRAINED UNPREDICTABLE behavior.

**Note**

- The stage 2 translation does not assign any allocation hints.
- The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
  - MemAttr[3:2] == 0b11, Normal memory, Outer Write-Back Cacheable.
  - MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

**Stage 2 Shareability attribute, for Normal memory**

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D4-41 shows the encoding of this field.

**Table D4-41 SH[1:0] field encoding for Normal memory, VMSAv8-64 translation table format**

SH[1:0]	Normal memory
00	Non-shareable
01	Reserved, CONSTRAINED UNPREDICTABLE <sup>a</sup>
10	Outer Shareable
11	Inner Shareable

- a. See *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6133 for the permitted CONSTRAINED UNPREDICTABLE behavior.

**Note**

- This encoding is the same as the shareability encoding described in *Stage 1 Shareability attribute, for Normal memory* on page D4-2091.
- The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes.

See *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D4-2097 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

### D4.5.3 Other fields in the VMSAv8-64 translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors:

- The Contiguous bit* on page D4-2094.
- IGNORED fields* on page D4-2095.
- Field reserved for software use* on page D4-2095.

## The Contiguous bit

When the value of the Contiguous bit is 1, it indicates that the entry is one of a number of adjacent translation table entries that point to a *contiguous output address range*. The required number of adjacent entries depends on the current translation granule size, as follows:

**4KB granule** 16 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 16 entries must be aligned in the translation table. If accessing a full-sized 4KB translation table, this means that the top 5 of the 9 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

**16KB granule** This bit indicates that adjacent translation table entries point to contiguous output address range that has the same permissions and attributes. With the 16KB granule, the number of contiguous entries indicated by setting this bit to 1 depends on the lookup level of the translation table:

**Level 2 lookup** The bit indicates 32 contiguous entries, giving a 1GB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 6 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

**Level 3 lookup** The bit indicates 128 contiguous entries, giving a 2MB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 4 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 128 translation table entries at the same translation table level.

**64KB granule** 32 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 32 entries must be aligned in the translation table. If accessing a full-sized 64KB translation table, this means that the top 8 of the 13 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Setting this bit to 1 means that the TLB can cache a single entry to cover the contiguous translation table entries.

This section defines the requirements for programming the Contiguous bit. [Possible errors in programming the translation table registers on page D4-2048](#) describes the effect of not meeting these requirements.

The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of the Contiguous bit.

TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues.

[Use of the Contiguous bit with hardware updates of the translation table entries on page D4-2089](#) describes the effect of hardware management of the Access flag and dirty state on the Contiguous bit.

---

### Note

When ARMv8.2-LVA is implemented, the level 1 block size for the 64KB granule does not support the Contiguous bit, and that field is RES0.

---

## IGNORED fields

In the VMSAv8-64 translation table descriptors, the following fields are identified as IGNORED, meaning the architecture guarantees that a PE makes no use of these fields:

- In the stage 1 table descriptors, bits[58:52].
- In the stage 1 and stage 2 block and page descriptors, bit[63] and bits[58:55].
- In the stage 1 and stage 2 block and page descriptors at any level above level 3, and in level 3 descriptors in an implementation that does not include ARMv8.2-TTPBHA, bits[62:59].

Of these fields:

- In the stage 1 and stage 2 block and page descriptors, bits[58:55] are reserved for software use, see [Field reserved for software use](#).
- In the stage 2 block and page descriptors, bit[63] is reserved for use by a System MMU.

## Field reserved for software use

The architecture reserves a 4-bit IGNORED field in the Block and Page table descriptors, bits[58:55], for software use. The definition of IGNORED means the architecture guarantees that hardware makes no use of this field.

### ———— Note ————

This means there is no need to invalidate the TLB if these bits are changed.

## D4.5.4 Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime

The Non-secure EL1&0 translation regime comprises two stage of translation, each of which can be enabled independently:

- Stage 1 translation is configured and controlled from EL1. When enabled, stage 1 translation can define access permissions independently for access from EL0 and for accesses from EL1.  
Stage 1 MMU faults are taken to EL1.
- When stage 2 translation is enabled, the stage 2 access controls defined at EL2:
  - Affect only the Non-secure stage 1 access permissions settings.
  - Take no account of whether the accesses are at EL1 or EL0.
  - Permit software executing at EL2 to assign a write-only attribute to a memory region.Stage 2 MMU faults are taken to EL2.

### ———— Note ————

In an implementation of virtualization, the attributes defined in the stage 2 translation tables mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The effects of the combination of attributes defined by the Hypervisor are functionally transparent to the Guest OS.

## Combining the stage 1 and stage 2 data access permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in [The AP\[2:1\] data access permissions, for stage 1 translations on page D4-2073](#).
- The stage 2 permissions described in [The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-2074](#).

The stage 1 and stage 2 permissions are combined as follows:

1. If an access is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an access is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.
3. If an access is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

### Combining the stage 1 and stage 2 instruction execution permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in [Stage 1 instruction access and execution permissions on page D4-2077](#).
- The stage 2 permissions described in [Stage 2 instruction execution permissions on page D4-2079](#).

The stage 1 and stage 2 permissions are combined as follows:

1. If an instruction fetch is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an instruction fetch is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.
3. If an instruction fetch is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

### Combining the stage 1 and stage 2 memory type attributes

[Table D4-42](#) shows the rules for combining the stage 1 and stage 2 memory type assignments.

**Table D4-42 Combining the stage 1 and stage 2 memory type assignments**

Rule	If either stage of translation assigns:	The resultant memory type is:
Device has precedence over Normal	Any Device memory type	A Device memory type
Non-Gathering has precedence over Gathering	A Device-nGxx memory type	A Device-nGxx memory type
Non-Reordering has precedence over Reordering	A Device-nGnRx memory type	A Device-nGnRx memory type
No Early write acknowledge has precedence over Early write acknowledge	The Device-nGnRnE memory type	The Device-nGnRnE memory type

Regardless of any shareability attribute obtained as described in [Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D4-2097](#):

- Any location for which the resultant memory type is any type of Device memory is always treated as Outer Shareable.
- Any location for which the resultant memory type is Normal Inner Non-cacheable, Outer Non-cacheable is always treated as Outer Shareable.

For information about how the cacheability attribute is obtained from the attributes assigned at each stage of translation see [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D4-2097](#).

The combining of the memory type attributes from the two stages of translation means a translation table walk for stage 1 translation can be made to a type of Device memory. If this occurs then:

- If the value of [HCR\\_EL2.PTW](#) is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of [HCR\\_EL2.PTW](#) is 1, then the memory access generates a stage 2 Permission fault.

### Combining the stage 1 and stage 2 cacheability attributes for Normal memory

For a Normal memory region, [Table D4-43](#) shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes.

**Table D4-43 Combining the stage 1 and stage 2 cacheability assignments for Normal memory**

Assignment in stage 1	Assignment in stage 2	Resultant cacheability
Non-cacheable	Any	Non-cacheable
Any	Non-cacheable	Non-cacheable
Write-Through Cacheable	Write-Through or Write-Back Cacheable	Write-Through Cacheable
Write-Through or Write-Back Cacheable	Write-Through Cacheable	Write-Through Cacheable
Write-Back Cacheable	Write-Back Cacheable	Write-Back Cacheable

### Combining the stage 1 and stage 2 shareability attributes for Normal memory

A memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation, if either:

- The resultant memory type attribute, described in [Combining the stage 1 and stage 2 memory type attributes on page D4-2096](#), is any type of Device memory.
- The resultant memory type attribute, described in [Combining the stage 1 and stage 2 memory type attributes on page D4-2096](#), is Normal memory, and the resultant cacheability, described in [Combining the stage 1 and stage 2 cacheability attributes for Normal memory](#), is Inner Non-cacheable, Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal, that is not Inner Non-cacheable, Outer Non-cacheable, [Table D4-44](#) shows how the stage 1 and stage 2 shareability assignments are combined.

**Table D4-44 Combining the stage 1 and stage 2 Shareability assignments for Normal memory<sup>a</sup>**

Assignment in stage 1	Assignment in stage 2	Resultant shareability
Outer Shareable	Any	Outer Shareable
Inner Shareable	Outer Shareable	Outer Shareable
Inner Shareable	Inner Shareable	Inner Shareable
Inner Shareable	Non-shareable	Inner Shareable
Non-shareable	Outer Shareable	Outer Shareable
Non-shareable	Inner Shareable	Inner Shareable
Non-shareable	Non-shareable	Non-shareable

a. Applies only if the Normal memory is not Inner Non-cacheable, Outer Non-cacheable, see text.

## D4.6 Virtualization Host Extensions

ARMv8.1 introduces the Virtualization Host Extensions that provide enhanced support for a Type 2 virtualization solution, where there is a Host OS, which is either more privileged than the hypervisor, or is a peer of the hypervisor.

The Virtualization Host Extensions only apply to an implementation that includes EL2 using AArch64.

### D4.6.1 State added by the Virtualization Host Extensions

The following state is added as part of the Virtualization Host Extensions:

- A new configuration bit, EL2 host (E2H), is added to [HCR\\_EL2](#). This only applies to execution in Non-secure state. When [SCR\\_EL3.NS](#)==0, [HCR\\_EL2.E2H](#) is treated as 0 for all purposes other than reading or writing the value of the register
- New registers added:
  - [TTBR1\\_EL2](#), which has the same format and contents as the [TTBR1\\_EL1](#).
  - [CONTEXTIDR\\_EL2](#), which has the same format and contents as [CONTEXTIDR\\_EL1](#).
- A new virtual timer is added to EL2 and is accessed using the registers: [CNTHV\\_CTL\\_EL2](#), [CNTHV\\_CVAL\\_EL2](#), and [CNTHV\\_TVAL\\_EL2](#). The registers take the same format as [CNTV\\_CTL\\_EL0](#), [CNTV\\_CVAL\\_EL0](#), and [CNTV\\_TVAL\\_EL0](#) respectively. The virtual offset is treated as 0 for this timer.

### D4.6.2 Behavior of HCR\_EL2.E2H

When the value of [HCR\\_EL2.E2H](#) is 0:

- There are no changes to the ARMv8 functionality other than the new state described in *State added by the Virtualization Host Extensions*.

———— **Note** ————

This means the translation regime controlled by [TCR\\_EL2](#) is called the EL2 translation regime.

- The contents of [TTBR1\\_EL2](#) are ignored by hardware, other than reads by an MRS instruction and writes by an MSR instruction.
- The Context ID matching breakpoint is disabled at EL2, and uses the value of [CONTEXTIDR\\_EL1](#) at EL0 and EL1.

When the value of [HCR\\_EL2.E2H](#) is 1:

- The translation regime controlled by [TCR\\_EL2](#) is the EL2&0 translation regime, and the behaviors of this translation regime differ from those of the EL2 translation regime.
- The EL2&0 translation regime behaves in the same way as stage 1 of the EL1&0 translation regime, with an upper address range translated by tables pointed to by [TTBR1\\_EL2](#). The existing [TTBR0\\_EL2](#) translates the lower address range of the EL2&0 translation regime and is extended to have the same contents and format as the [TTBR0\\_EL1](#).
- The translation tables used in the EL2&0 translation regime take the same format as the EL1&0 translation regime. EL2 accesses are treated as privileged in this format.
- Context ID matching can occur at EL2. When executing at EL2, a Context ID matching breakpoint uses [CONTEXTIDR\\_EL2](#).
- [VMID](#) and [VMID](#) + Context ID matching breakpoints do not match at EL2.
- The virtual offset is treated as 0 when [CNTVCT\\_EL0](#) is read from EL2.
- The Privileged Access Never mechanism applies to accesses from EL2 to a virtual address which has access permitted in the EL2&0 translation regime.

- The following registers are redefined:
  - CNTHCTL\_EL2.
  - CPTR\_EL2.
  - TCR\_EL2.

If  $\text{HCR\_EL2}\{E2H, TGE\} = \{1, 0\}$ , then all accesses from EL1 and EL0 are not included in the EL2&0 translation regime.

If  $\text{HCR\_EL2}\{E2H, TGE\} = \{1, 1\}$ :

- The EL2&0 translation regime is used when executing at Non-secure EL0 as well as when executing at EL2, where Non-secure EL0 accesses are treated as unprivileged.

———— **Note** ————

Accesses from Non-secure EL1 are not possible under this configuration.

- In EL2, the unprivileged instructions LDTR, LDTRB, LDTRH, LDTRSB, LDTRSH, LDTRSW, STTR, STTRB, and STTRH act as if they are executing at Non-secure EL0 for permission and watchpoint checking.
- Except for the purpose of reading the value held in the register, some fields in [HCR\\_EL2](#) and all fields in [HSTR\\_EL2](#) are treated as having a specific value.
- [SCTLR\\_EL2](#) is redefined to include additional fields from [SCTLR\\_EL1](#), and to apply to execution at Non-secure EL0.
- The following timer registers, and their equivalent AArch32 registers, are redefined to access the associated \_EL2 register, rather than accessing the \_EL0 register when in EL0:
  - CNTP\_CTL\_EL0.
  - CNTP\_CVAL\_EL0.
  - CNTP\_TVAL\_EL0.
  - CNTV\_CTL\_EL0.
  - CNTV\_CVAL\_EL0.
  - CNTV\_TVAL\_EL0.

For some information on registers that are redirected, see [System and Special-purpose register redirection on page D4-2100](#).

- When executing at Non-secure EL0, a Context ID matching breakpoint uses [CONTEXTIDR\\_EL2](#).
- [VMID](#) and [VMID](#) + Context ID matching breakpoints do not match at Non-secure EL0.
- The [CPACR\\_EL1](#) register does not cause any instructions to be trapped to EL1, regardless of the contents of [CPACR\\_EL1](#).
- The [CNTKCTL\\_EL1](#) register does not cause any instructions to be trapped to EL1, and the event stream event caused by the [CNTKCTL\\_EL1](#) is disabled, regardless of the contents of [CNTKCTL\\_EL1](#).
- The virtual offset is treated as 0 when [CNTVCT\\_EL0](#) is read from EL0 or EL2.
- The TLB maintenance and address translation instructions that apply to the EL1&0 translation regime are redefined to apply to the EL2&0 translation regime. See [A64 system instructions for address translation on page C5-427](#) and [A64 system instructions for TLB maintenance on page C5-454](#).
- When executing at EL2 or Non-secure EL0, any physical interrupt that is configured to be taken at EL2 is subject to the Process state interrupt mask. If the mask bit is set, then the corresponding interrupt will not be taken. If the mask bit is not set, then the corresponding interrupt will be taken. See [Asynchronous exception masking on page D1-1836](#).
- When an exception is taken from EL0 to EL2, the value of the [HCR\\_EL2.RW](#) bit is not considered when determining the exception vector offset to use. [Table D1-7 on page D1-1800](#) lists the vector offsets used when an exception is taken from EL0.

### D4.6.3 System and Special-purpose register redirection

When [ARMv8.1-VHE](#) is implemented, and [HCR\\_EL2.E2H](#) is set to 1, when executing at EL2, some EL1 System register access instructions are redefined to access the equivalent EL2 register. Register access behavior is unchanged when executing at EL3, EL1, or EL0.

[Table D4-45](#) shows the System register access instruction encodings that are redirected to the equivalent EL2 register when the named mnemonic is used.

**Table D4-45 System register redirection**

System register access instruction encoding					Mnemonic	Equivalent register accessed at EL2
op0	op1	CRn	CRm	op2		
3	0	1	0	0	SCTLR_EL1	<a href="#">SCTLR_EL2</a>
				2	CPACR_EL1	<a href="#">CPTR_EL2</a>
		2	0	0	TTBR0_EL1	<a href="#">TTBR0_EL2</a>
				1	TTBR1_EL1	<a href="#">TTBR1_EL2</a>
				2	TCR_EL1	<a href="#">TCR_EL2</a>
		5	1	0	AFSR0_EL1	<a href="#">AFSR0_EL2</a>
				1	AFSR1_EL1	<a href="#">AFSR1_EL2</a>
				2	ESR_EL1	<a href="#">ESR_EL2</a>
		6	0	0	FAR_EL1	<a href="#">FAR_EL2</a>
		10	2	0	MAIR_EL1	<a href="#">MAIR_EL2</a>
				3	AMAIR_EL1	<a href="#">AMAIR_EL2</a>
		12	0	0	VBAR_EL1	<a href="#">VBAR_EL2</a>
		13	0	1	CONTEXTIDR_EL1	<a href="#">CONTEXTIDR_EL2</a>
		14	1	0	CNTKCTL_EL1	<a href="#">CNTHCTL_EL2</a>
	3	14	2	0	CNTP_TVAL_EL0	<a href="#">CNTHP_TVAL_EL2</a>
				1	CNTP_CTL_EL0	<a href="#">CNTHP_CTL_EL2</a>
				2	CNTP_CVAL_EL0	<a href="#">CNTHP_CVAL_EL2</a>
3	3	14	3	0	CNTV_TVAL_EL0	<a href="#">CNTHV_TVAL_EL2</a>
				1	CNTV_CTL_EL0	<a href="#">CNTHV_CTL_EL2</a>
				2	CNTV_CVAL_EL0	<a href="#">CNTHV_CVAL_EL2</a>

Table D4-46 shows the Special-purpose register access instruction encodings that are redirected to the equivalent EL2 register when the named mnemonic is used.

Table D4-46 Special-purpose register redirection

Special-purpose register access instruction encoding			Mnemonic	Equivalent register accessed at EL2
op1	CRm	op2		
0	0	0	SPSR_EL1	SPSR_EL2
		1	ELR_EL1	ELR_EL2

#### D4.6.4 System and Special-purpose register aliasing

New register encodings, and aliases, are provided so that software executing at EL2 can access the EL1 registers for which accesses from EL2 are redirected as described in [System and Special-purpose register redirection on page D4-2100](#). These aliases can also be used at EL3, but are UNDEFINED at EL1 and EL0.

Table D4-47 shows the System register access instruction encodings that are aliased.

Table D4-47 System register aliases

System register access instruction encoding					Mnemonic	Register accessed
op0	op1	CRn	CRm	op2		
3	5	1	0	0	SCTLR_EL12	SCTLR_EL1
				2	CPACR_EL12	CPACR_EL1
		2	0	0	TTBR0_EL12	TTBR0_EL1
				1	TTBR1_EL12	TTBR1_EL1
				2	TCR_EL12	TCR_EL1
		5	1	0	AFSR0_EL12	AFSR0_EL1
				1	AFSR1_EL12	AFSR1_EL1
			2	0	ESR_EL12	ESR_EL1
		6	0	0	FAR_EL12	FAR_EL1
		10	2	0	MAIR_EL12	MAIR_EL1
				3	AMAIR_EL12	AMAIR_EL1
		12	0	0	VBAR_EL12	VBAR_EL1
		13	0	1	CONTEXTIDR_EL12	CONTEXTIDR_EL1
		14	1	0	CNTKCTL_EL12	CNTKCTL_EL1
				2	CNTP_TVAL_EL02	CNTP_TVAL_EL0
				1	CNTP_CTL_EL02	CNTP_CTL_EL0
				2	CNTP_CVAL_EL02	CNTP_CVAL_EL0

**Table D4-47 System register aliases (continued)**

System register access instruction encoding					Mnemonic	Register accessed
op0	op1	CRn	CRm	op2		
3	5	14	3	0	CNTV_TVAL_EL02	CNTV_TVAL_EL0
				1	CNTV_CTL_EL02	CNTV_CTL_EL0
				2	CNTV_CVAL_EL02	CNTV_CVAL_EL0

Table D4-48 shows the Special-purpose register aliasing.

**Table D4-48 Special-purpose register aliases**

Special-purpose register access instruction encoding			Register name	Register accessed
op1	CRm	op2		
5	0	0	SPSR_EL12	SPSR_EL1
		1	ELR_EL12	ELR_EL1

## D4.7 MMU faults

In a VMSAv8-64 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

<b>Debug exception</b>	An exception caused by the debug configuration, see <a href="#">Chapter D2 AArch64 Self-hosted Debug</a> .
<b>Alignment fault</b>	An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information, see <a href="#">Alignment support on page B2-102</a> .
<b>MMU fault</b>	An MMU fault is a fault generated by the fault checking sequence for the current translation regime. The remainder of this section describes MMU faults.
<b>External abort</b>	Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault.

Collectively, these mechanisms are called *aborts*.

In AArch64 state MMU faults are synchronous exceptions that are reported as either:

- Data Aborts.
- Instruction Aborts

---

**Note**

---

Instruction Aborts report any synchronous memory abort on an instruction fetch.

---

External aborts can be reported synchronously or asynchronously. Asynchronous external aborts are reported using the SError interrupt. For more information, see [External aborts on page D3-1997](#).

An access that causes an abort is said to be aborted, and uses the *Fault Address Registers* (FARs) and *Exception Syndrome Registers* (ESRs) to record context information.

For more information, see [Synchronous exception types, routing and priorities on page D1-1826](#).

The Exception level that the MMU fault is taken to depends on the translation regime that generated the fault. The fault context saved in the appropriate `ESR_ELx`, where ELx is the Exception level that the fault is taken to, is dependent on whether:

- The MMU fault is due to an Instruction or Data Abort.
- The exception is taken from the same or a lower Exception level.

Software stepping, which is a debug feature, and a PC alignment fault exception are the only exceptions that are higher priority than an Instruction Abort. Only watchpoints are at a lower priority than Data Aborts in the exception priority hierarchy. For more information, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#).

The following sections describe the abort mechanisms:

- [Types of MMU faults on page D4-2104](#).
- [The MMU fault-checking sequence on page D4-2106](#).
- [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-2110](#).
- [Pseudocode description of the MMU faults on page D4-2112](#).

## D4.7.1 Types of MMU faults

This section describes the faults that might be detected during one of the fault-checking sequences described in *The MMU fault-checking sequence* on page D4-2106. The following list includes all the types of exceptions that can occur:

- Alignment fault on a data access, see *Alignment support* on page B2-102.
- Permission fault, see *Permission fault*.
- Translation fault, see *Translation fault* on page D4-2105.
- Address size fault, see *Address size fault* on page D4-2105.
- Synchronous external abort on a translation table walk, see *External abort on a translation table walk* on page D4-2105.
- Access flag fault, see *Access flag fault* on page D4-2106.
- TLB conflict abort, see *TLB conflict aborts* on page D4-2118.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as Device.

The following subsections describe the MMU faults that are not described elsewhere in this Manual.

### Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See *About access permissions* on page D4-2071 for information about conditions that cause a Permission fault.

A TLB might hold a translation table entry that causes a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access.

This maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache maintenance instructions cannot generate Permission faults, except that:

- A stage 1 translation table walk performed as part of a cache maintenance instruction can generate a stage 2 Permission fault as described in *Stage 2 fault on a stage 1 translation table walk* on page D4-2109.
- When the value of `SCTLR_EL1.UCI` is 1, enabling EL0 execution of the `DC CVAU`, `DC CVAC`, `DC CVAP`, `DC CIVAC`, and `IC IVAU` instructions:
  - Executing a `DC CVAU`, `DC CVAC`, `DC CVAP`, or `DC CIVAC` instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault.
  - It is IMPLEMENTATION DEFINED whether executing a `IC IVAU` instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault.
- A `DC IVAC` instruction requires write permission to the address it invalidates, otherwise it generates a Permission fault.

#### ———— Note ————

- Execution of the `DCIMVAC` instruction in AArch32 state does not have this write permission requirement.
- When Non-secure EL1&0 stage 2 address translation is enabled, a `DC IVAC` instruction executed in Non-secure state performs a cache clean and invalidate, meaning it performs the same invalidation as a `DC CIVAC` instruction, as described in *Effects of virtualization and security on the cache maintenance instructions* on page D3-1990.

The Data Cache Zero instruction, `DC ZVA`, operates as set of stores to each byte within the block being accessed, and therefore it generates a Permission fault if the translation system does not permit writes to these locations.

## Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information, see *VMSAv8-64 translation table format descriptors* on page D4-2060.

In addition, a Translation fault is generated if the input address for a translation either does not map onto an address range of a **TTBR\_ELx**, or the **TTBR\_ELx** range that it maps onto is disabled. In these cases, the fault is reported as a level 0 Translation fault on the translation stage at which the mapping to a region described by a **TTBR\_ELx** failed.

A data or unified cache maintenance by **VA** instruction can generate a Translation fault. If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by **VA** instruction can generate a Translation fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by **VA** operation can generate a Translation fault.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by **VA** to the Point of Unification instruction can generate a Translation fault.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

## Address size fault

An Address size fault can be generated at any level of lookup.

An Address size fault is generated if one of the following has nonzero address bits above the output address size, for the current stage of translation:

- The **TTBR\_ELx** used for the translation.
- A translation table entry.
- The output address of the translation.

For an Address size fault generated because the **TTBR\_ELx** used for the translation has nonzero address bits above the output address size, the reported fault code indicates a fault at level 0. Otherwise, the reported fault code indicates the lookup level at which the fault occurred.

A data or unified cache maintenance by **VA** instruction can generate an Address size fault. If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by **VA** instruction can generate an Address size fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by **VA** operation can generate an Address size fault.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by **VA** to the Point of Unification instruction can generate an Address size fault.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

For more information on Address size faults, see *Output address size* on page D4-2015.

## External abort on a translation table walk

An external abort on a translation table walk can be either synchronous or asynchronous. An external abort on a translation table walk is reported:

- If the external abort is synchronous, using:
  - A synchronous Instruction Abort exception if the translation table walk is for an instruction fetch.
  - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the external abort is asynchronous, using the SError interrupt exception.

### **Behavior of external aborts on a translation table walk caused by address translation instructions**

The address translation instructions summarized in [Address translation instructions, functional group on page G4-4737](#) require translation table walks. An external abort can occur in the translation table walk. This is reported as follows:

- If the external abort is synchronous, using a synchronous Data Abort exception.
- If the external abort is asynchronous, using the SError interrupt exception.

For more information, see [Synchronous faults generated by address translation instructions on page D4-2057](#).

### **Access flag fault**

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if a translation table descriptor with the Access flag bit set to 0 is used.

For more information about the Access flag bit, see [VMSAv8-64 translation table format descriptors on page D4-2060](#).

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to execute any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance by VA instructions can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see [The Access flag on page D4-2081](#).

## **D4.7.2 The MMU fault-checking sequence**

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

- If an instruction fetch faults, it generates an Instruction Abort.
- If a data memory access faults, it generates a Data Abort.

MMU fault checking is performed for each stage of address translation.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see [About address translation and supported input address ranges on page D4-2011](#).

### **———— Note ————**

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in [TLB conflict aborts on page D4-2118](#).

[Types of MMU faults on page D4-2104](#) describes the faults that an MMU fault-checking sequence can report.

[Figure D4-17 on page D4-2107](#) shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, if the translation is stage 1 of the Non-secure EL1&0 translation regime, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

**Figure D4-17 Fetching the descriptor in a VMSAv8-64 translation table walk**

Figure D4-18 on page D4-2108 shows the full VMSA fault checking sequence, including the alignment check on the initial access.

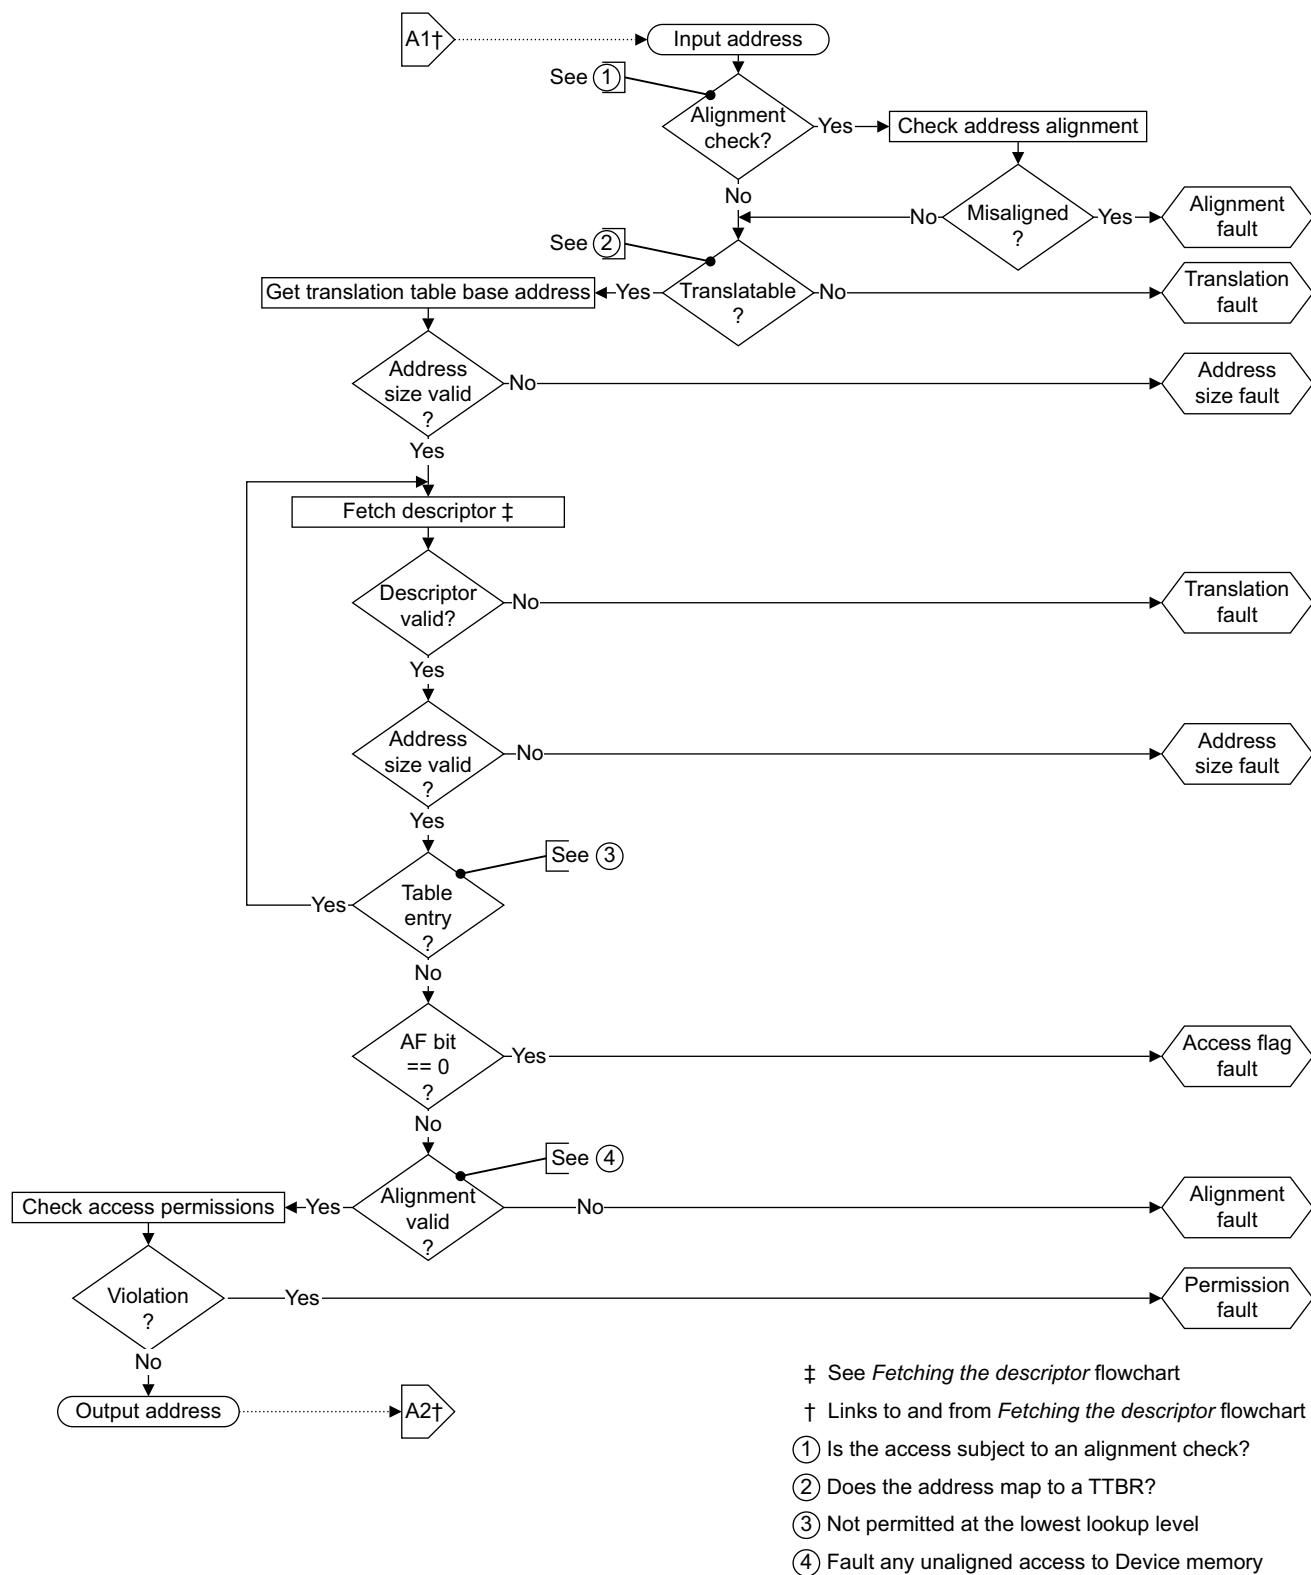

Figure D4-18 VMSAv8-64 fault checking sequence

## Stage 2 fault on a stage 1 translation table walk

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous external abort on the memory access.

If [SCR\\_EL3.EA](#) is set to 1, a synchronous external abort is taken to EL3. Otherwise, these faults are reported as stage 2 memory aborts. [ESR\\_EL2.ISS\[7\]](#) is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see [Use of the ESR\\_EL1, ESR\\_EL2, and ESR\\_EL3 on page D1-1801](#).

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the Device attribute assigned on the stage 2 translation of the address accessed. When the [HCR\\_EL2.PTW](#) bit is set to 1, such an access generates a stage 2 Permission fault.

### ———— Note ————

On most systems, such a mapping to Device memory on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of [HCR\\_EL2.PTW](#). Therefore, if [HCR\\_EL2.PTW](#) is changed without changing the current [VMID](#), the TLBs must be invalidated before executing in Non-secure EL1 or Non-secure EL0 state. For more information see [Changing HCR\\_EL2.PTW on page D4-2132](#).

A cache maintenance instruction executed at Non-secure EL1 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault. If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by [VA](#) instruction can generate a Permission fault in this way.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by [VA](#) to the Point of Unification instruction can generate a Permission fault in this way.

## The level associated with MMU faults

For MMU faults, [Table D4-49](#) shows how the LL bits in the [ESR\\_ELx.STATUS](#) fields encode the lookup level associated with the fault.

**Table D4-49 Use of LL bits to encode the lookup level at which the fault occurred**

LL bits	Meaning
00	Level 0 of translation or translation table base register.
01	Level 1.
10	Level 2.
11	Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.

- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see [Synchronous external aborts from address translation caching structures](#) on page D4-2111

### D4.7.3 AArch64 state prioritization of synchronous aborts from a single stage of address translation

[Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1827 describes the prioritization of exceptions taken to an Exception level that is using AArch64. This section gives additional information about the prioritization of MMU faults from VMSAv8-64 translation regimes.

#### ————— Note —————

The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a VMSAv8-64 translation regime. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in [AArch32 state prioritization of synchronous aborts from a single stage of address translation](#) on page G4-4660.

For a single stage of translation in a VMSAv8-64 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list:

- For memory accesses that undergo two stages of translation, the *italic entries show where the faults from the stage 2 translation can occur*. A stage 2 fault within a stage 1 translation table walk follows the same prioritization of faults:
- For synchronous external aborts from translation table walks see also [Synchronous external aborts from address translation caching structures](#) on page D4-2111.

The priority order, from highest priority to lowest priority, is:

1. Alignment fault not caused by memory type. This is possible for a stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring a [TTBR\\_ELx](#) that is disabled. This includes [VTCR\\_EL2.SL0](#) being inconsistent with [VTCR\\_EL2.T0SZ](#) or programmed to a reserved value.
3. Address size fault on a [TTBR\\_ELx](#) caused by either:
  - The check on [TCR\\_EL1.IPS](#), [TCR\\_EL2.PS](#), [TCR\\_EL3.PS](#), or [VTCR\\_EL2.PS](#).
  - The [PA](#) being out of the range implemented.
4. *Second stage abort on a level 0 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the [PA](#) being out of the range implemented. This is second stage abort during a first stage translation table walk.*
5. Synchronous parity or ECC error on a level 0 lookup of a translation table walk.
6. Synchronous external abort on a level 0 lookup level of a translation table walk.
7. Translation fault on a level 0 translation table entry.
8. Address Size fault a level 0 lookup translation table entry caused by either:
  - The check on [TCR\\_EL1.IPS](#), [TCR\\_EL2.PS](#), [TCR\\_EL3.PS](#), or [VTCR\\_EL2.PS](#).
  - The output address being out of the range implemented.
9. *Second stage abort on a level 1 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the [PA](#) being out of the range implemented. This is second stage abort during a first stage translation table walk.*
10. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.
11. Synchronous external abort on a level 1 lookup level of a translation table walk.

12. Translation fault on a level 1 translation table entry.
13. Address size fault on a level 1 lookup translation table entry caused by either:
  - The check on [TCR\\_EL1.IPS](#), [TCR\\_EL2.PS](#), [TCR\\_EL3.PS](#), or [VTCR\\_EL2.PS](#).
  - The output address being out of the range implemented.
14. *Second stage abort on a level 2 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the [PA](#) being out of the range implemented. This is second stage abort during a first stage translation table walk.*
15. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.
16. Synchronous external abort on a level 2 lookup level of a translation table walk.
17. Translation fault on a level 2 translation table entry.
18. Address size fault on a level 2 lookup translation table entry caused by either:
  - The check on [TCR\\_EL1.IPS](#), [TCR\\_EL2.PS](#), [TCR\\_EL3.PS](#), or [VTCR\\_EL2.PS](#).
  - The output address being out of the range implemented.
19. *Second stage abort on a level 3 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the [PA](#) being out of the range implemented. This is second stage abort during a first stage translation table walk.*
20. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.
21. Synchronous external abort on a level 3 lookup level of a translation table walk.
22. Translation fault on a level 3 translation table entry.
23. Address size fault on a level 3 lookup translation table entry caused by either:
  - The check on [TCR\\_EL1.IPS](#), [TCR\\_EL2.PS](#), [TCR\\_EL3.PS](#), or [VTCR\\_EL2.PS](#).
  - The output address being out of the range implemented.
24. Access Flag fault.
25. Alignment fault caused by the memory type.
26. Permission fault.
27. *A fault from the stage 2 translation of the memory access. When stage 2 address translation is enabled this includes an Address size fault caused by the [PA](#) being out of the range implemented.*
28. Synchronous parity or ECC error on the memory access.
29. Synchronous External Abort on the memory access.

#### **Note**

- The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.
- The prioritization of IMPLEMENTATION DEFINED MMU faults for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

### **Synchronous external aborts from address translation caching structures**

A caching structure used for caching translation table walks might support:

- An arbitrary number of levels of translation table lookup.
- One or more stages of translation, that might not correspond to the stages of an address translation lookup.

This might mean that, on a synchronous external aborts arising from the caching structure, including parity or ECC errors, the PE cannot precisely determine one or both of the translation stage and level of lookup at which the error occurred. In this case:

- If the PE cannot determine precisely the translation stage at which the error occurred, it is reported and prioritized as a stage 1 error.
- If the PE cannot determine precisely the lookup level at which the error occurred, the level is reported and prioritized as either:
  - The lowest-numbered level that could have given rise to the error.
  - Level 0 if the PE cannot determine any information about the level.

#### D4.7.4 Pseudocode description of the MMU faults

The following functions generate fault records that describe MMU faults:

- [AArch64.AccessFlagFault\(\)](#).
- [AArch64.AddressSizeFault\(\)](#).
- [AArch64.PermissionFault\(\)](#).
- [AArch64.TranslationFault\(\)](#).

[Abort exceptions on page D3-2002](#) describes how fault records are used.

## D4.8 Translation Lookaside Buffers (TLBs)

*Translation Lookaside Buffers* (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and the VMSA provides TLB maintenance instructions for the management of TLB contents.

---

### Note

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

---

The following sections describe the architectural requirements for Translation Lookaside Buffers (TLBs) and their maintenance:

- [Use of ASIDs and VMIDs to reduce TLB maintenance requirements.](#)
- [About ARMv8 Translation Lookaside Buffers \(TLBs\) on page D4-2115.](#)
- [TLB maintenance requirements and the TLB maintenance instructions on page D4-2119.](#)

In these descriptions, TLB entries for a translation regime for a particular Exception level are *out of context* when executing at a higher Exception level.

### D4.8.1 Use of ASIDs and VMIDs to reduce TLB maintenance requirements

To reduce the need for TLB maintenance on context switches, the lookups from some translation regimes can be associated with an ASID, or with an ASID and a VMID, as follows:

**ASID** For stage 1 translations that support two VA ranges the VMSA can distinguish between *Global pages* and *Process-specific pages*. The *Address Space Identifier* (ASID) identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

For these stage 1 translations, each of [TTBR0\\_ELx](#) and [TTBR1\\_ELx](#) has a valid ASID field, and [TCR\\_ELx.A1](#) determines which of these holds the current ASID.

---

### Note

The selected ASID applies regardless of which set of translation tables are used. For example, when the value of [TCR\\_ELx.A1](#) is 0, any translation table lookup using this stage of translation is associated with the ASID from [TTBR0\\_ELx.ASID](#), regardless of whether the translation lookup uses [TTBR0\\_ELx](#) or [TTBR1\\_ELx](#).

---

See also [ASID size on page D4-2114](#) and [Global and process-specific translation table entries on page D4-2116](#).

For a symmetric multiprocessor cluster where a single operating system is running on the set of processing elements, the ARM architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all processing elements in the system.

**VMID** For the Non-secure EL1&0 translation regime, the *virtual machine identifier* (VMID) identifies the current virtual machine, with its own independent [ASID](#) space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another if the virtual machines have different VMIDs.

[VTTBR\\_EL2.VMID](#) holds the current VMID.

## Common not private translations

In an implementation that includes ARMv8.2-TTCNP, multiple PEs in the same Inner Shareable domain can use the same translation table entries for a given stage of translation in a particular translation regime. This sharing is enabled by the TTBR\_ELx.CnP field for the stage of address translation.

When the value of a TTBR\_ELx.CnP field is 1, translation table entries pointed to by that TTBR\_ELx are shared with all other PEs in the Inner Shareable domain for which the following conditions are met:

- The corresponding TTBR\_ELx.CnP field has the value 1.
- That TTBR\_ELx relates to the same translation regime.

---

### Note

- For TTBR0\_EL1 the current Security state determines whether the register relates to the Secure EL1&0 translation regime, or to the Non-secure EL1&0 translation regime.
  - For TTBR0\_EL2 the value of HCR\_EL2.E2H determines whether the register relates to the EL2 translation regime, or to the EL2&0 translation regime.
- 

- If an ASID applies to the stage of translation corresponding to that TTBR\_ELx then the current ASID value must be the same for all of the PEs that are sharing entries.
- If a VMID applies to the stage of translation corresponding to that TTBR\_ELx then the current VMID value must be the same for all of the PEs that are sharing entries.

Where a TLB combines information from stage 1 and stage 2 translation table entries into a single entry, this entry can be shared between different PEs only if the value of the TTBR\_ELx.CnP bit is 1 for both stage 1 and stage 2 of the translation table walk.

The TTBR\_ELx.CnP bit can be cached in a TLB.

For a given TTBR\_ELx, if the value of TTBR\_ELx.CnP is 1 on multiple PEs in the same Inner Shareable domain, and those PEs meet the other conditions for sharing translation table entries as defined in this section, but those TTBR\_ELxs do not point to the same translation table entries, then the system is misconfigured, and performing an address translation using that TTBR\_ELx:

- Might generate multiple hits in the TLB, and as a result generate an exception that is reported using the TLB conflict fault code, see *TLB conflict aborts* on page D4-2118.
- Otherwise, has a **CONSTRAINED UNPREDICTABLE** result, as described in *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-6120.

## ASID size

In VMSAv8-64, the **ASID** size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and **ID\_AA64MMFR0\_EL1.ASIDBits** identifies the supported size.

When an implementation supports a 16-bit **ASID**, **TCR\_ELx.AS** selects whether the top 8 bits of the **ASID** are used.

When the value of **TCR\_ELx.AS** is 0, **ASID[15:8]**:

- Are ignored by hardware for every purpose other than direct reads of **TTBR0\_ELx.ASID** and **TTBR1\_ELx.ASID**.
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

---

### Note

VMSAv8-32 uses an 8-bit **ASID**. For backwards compatibility, when executing using translations controlled from an Exception level that is using AArch32, the **ASID** size remains at 8 bits. If the implementation supports 16-bit **ASIDs**, the 8-bit **ASID** used is zero-extended to 16 bits.

---

## VMID size

From ARMv8.1, the **VMID** size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and **ID\_AA64MMFR1\_EL1.VMIDBits** identifies the supported size.

When **ARMv8.1-VMID16** is implemented, **VTTBR\_EL2[63:48]** contains the 16-bit **VMID**.

When an implementation supports a 16-bit **VMID**, **VTSCR\_EL2.VS** selects whether the top 8 bits of the **VMID** are used.

When the value of **VTSCR\_EL2.VS** is 0, **VMID[63:56]**:

- Are ignored by hardware for every purpose other than reads of **ID\_AA64MMFR1\_EL1**.
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

**ARMv8.1-VMID16** is only supported when EL2 is using AArch64.

## D4.8.2 About ARMv8 Translation Lookaside Buffers (TLBs)

*Translation Lookaside Buffers* (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement for every memory access to perform a translation table walk in memory. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Permission fault might be held in the TLB.
- When address translation is enabled, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not from a translation regime for an Exception level that is lower than the current Exception level can be allocated to a TLB at any time. The only translation table entries guaranteed not to be held in a TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

### ————— **Note** —————

A TLB can hold a translation table entry that does not itself generate a Translation fault but that points to a subsequent table in the translation table walk. This is referred to as *intermediate caching* of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not have been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- [Global and process-specific translation table entries on page D4-2116.](#)
- [TLB matching on page D4-2116.](#)
- [TLB behavior at reset on page D4-2117.](#)
- [TLB lockdown on page D4-2117.](#)
- [TLB conflict aborts on page D4-2118.](#)

See also [TLB maintenance requirements and the TLB maintenance instructions on page D4-2119.](#)

## Global and process-specific translation table entries

In a VMSA implementation, system software can divide the virtual memory map used by a stage of translation that supports two VA ranges into global and non-global regions, indicated by the nG bit in the translation table descriptors:

- nG == 0**      The translation is global, meaning the region is available for all processes.
- nG == 1**      The translation is non-global, or process-specific, meaning it relates to the current [ASID](#), as defined by:
- [TTBR0\\_ELx.ASID](#), if the value of [TCR\\_ELx.A1](#) is 0.
  - [TTBR1\\_ELx.ASID](#), if the value of [TCR\\_ELx.A1](#) is 1.

As indicated by the nG field definitions, each non-global region has an associated [ASID](#). These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

### ———— Note ————

- The selected [ASID](#) applies to the translation of any address for which the value of the nG bit is 1, regardless of whether the address is translated based on [TTBR0\\_ELx](#) or on [TTBR1\\_ELx](#).
- In an implementation that does not include [ARMv8.1-VHE](#), the only stage of translation that supports two VA ranges is stage 1 of the EL1&0 translation regime. In an implementation that includes [ARMv8.1-VHE](#) stage 1 of the EL2&0 translation regime also supports two VA ranges.

[ASIDs](#) are supported only by stage 1 translations that support two VA ranges. Stage 2 translations, and stage 1 translations that support only a single VA range do not support [ASIDs](#), and all descriptors in these regimes are treated as global.

In a translation regime that supports global and non-global translations, translation table entries from lookup levels other than the final level of lookup are treated as being non-global, regardless of the value of the nG bit.

When a PE is using the VMSAv8-64 translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information, see [Control of Secure or Non-secure memory access](#) on page D4-2070.

## TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in [TLB maintenance requirements and the TLB maintenance instructions](#) on page D4-2119 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular [ASID](#) and [VMID](#) are changed without suitable invalidation of the TLB. This can occur only if the architecturally-required break-before-make sequence described in [Using break-before-make when updating translation table entries](#) on page D4-2120 is not used. If the break-before make sequence is not used, the TLB can hold two mappings for the same address, and this:

- Might generate an exception that is reported using the TLB conflict fault code, see [TLB conflict aborts](#) on page D4-2118.
- Might lead to CONSTRAINED UNPREDICTABLE behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. For more information, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values](#) on page K1-6120.

## TLB behavior at reset

The ARM architecture does not require a reset to invalidate the TLBs. The architecture recognizes that an implementation might require caches, including TLBs, to maintain their contents over a system reset. Possible reasons for doing so include power management and debug requirements.

Therefore, for ARMv8:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- All TLBs are disabled from reset. All stages of address translation are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information, see [Controlling address translation stages on page D4-2012](#).
- An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device.  
ARM recommends that if an invalidation routine is required for this purpose, the routine is based on the TLB maintenance instructions described in [TLB maintenance instructions on page D4-2121](#).

Similar rules apply to cache behavior, see [Behavior of caches at reset on page D3-1980](#).

## TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- VMSAv8-64 does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that a region of the system instruction encoding space is reserved for IMPLEMENTATION DEFINED functions, see [Reserved encodings for IMPLEMENTATION DEFINED registers on page C5-334](#). An implementation might use some of these encodings to implement TLB lockdown functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.

In an implementation that includes EL2, exceptions generated as a result of TLB lockdown when executing in Non-secure EL1 or Non-secure EL0 state can be routed to either:

- Non-secure EL1, as a Data Abort exception.
- Non-secure EL2, as a Hyp Trap exception.

For more information, see [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1857](#).

## TLB conflict aborts

If an address matches multiple entries in the TLB, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

### ———— Note ————

An address can hit multiple entries in the TLB if the TLB has been invalidated inappropriately, for example if TLB invalidation required by the architecture has not been performed.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses. A TLB conflict abort:

- On an instruction fetch is reported as an Instruction Abort, see [ISS encoding for an exception from an Instruction Abort on page D7-2275](#).
- On a data access is reported as a Data Abort, see [ISS encoding for an exception from a Data Abort on page D7-2277](#).

ARMv8 defines the Fault status encoding of 0b110000 for TLB conflict aborts. On a TLB conflict abort, the returned syndrome includes the address that generated the fault. That is, it includes the address that was being looked up in the TLB.

It is IMPLEMENTATION DEFINED whether a TLB conflict abort is a stage 1 abort or a stage 2 abort.

### ———— Note ————

A stage 2 abort cannot be generated if stage 2 of the Non-secure EL1&0 translation regime is disabled.

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of a TLB that can generate the abort. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

If an address matches multiple entries in the TLB and no TLB conflict abort is generated, the resulting behavior is CONSTRAINED UNPREDICTABLE, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6120](#). The CONSTRAINED UNPREDICTABLE behavior must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Exception level.

## D4.9 TLB maintenance requirements and the TLB maintenance instructions

*Translation Lookaside Buffers* (TLBs) are an implementation mechanism that caches translations or translation table entries. The ARM architecture does not specify the form of any TLB structures, but defines the mechanisms by which TLBs can be maintained. The following sections describe the VMSA TLB maintenance instructions:

- [General TLB maintenance requirements](#).
- [TLB maintenance instructions on page D4-2121](#).

See also:

- [Maintenance requirements on changing System register values on page D4-2132](#).
- [Atomicity of register changes on changing virtual machine on page D4-2020](#).

### D4.9.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures to ensure that changes to the translation tables are reflected correctly in those TLB caching structures.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault, provided that the entry does not, itself, cause a Translation fault, an Address size fault, or an Access Flag fault. This means that the entries that can be cached include:

- Entries in translation tables that point to subsequent tables to be used in that stage of translation.
- Stage 2 translation table entries used as part of a stage 1 translation table walk
- Stage 2 translation table entries used to translate the output address of the stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are used during a translation table walk and that are distinct from the data caches in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction of the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries, and in particular for a translation regime that involves two stages of translation, it is recognized that such caching structures might contain:

- Entries containing information from stage 1 translation table entries, at any level of the translation table walk.
- Entries containing information from stage 2 translation table entries, at any level of the translation table walk.
- Entries that combine information from stage 1 and stage 2 translation table entries, at any level of the translation table walk.

#### ———— **Note** ————

For the purpose of TLB maintenance, the term *TLB entry* denotes any structure, including temporary working registers in translation table walk hardware, that holds a translation table entry.

Where a TLB maintenance instruction is:

- Required to apply to stage 1 entries, then it must apply to any cached entries in caching structures that include any stage 1 information that are used to translate the address being invalidated.

#### ———— **Note** ————

- Where stage 1 information has been cached in multiple TLB entries, as could occur from splintering a page when caching in the TLB, then the invalidation must apply to each cached entry containing stage 1 information from the page that is used to translate the address being invalidated, regardless of whether or not that cached entry would be used to translate the address being invalidated.
- As stated in [Global and process-specific translation table entries on page D4-2116](#), translation table entries from levels of translation other than the final level are treated as being non-global. ARM expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their **ASID**, regardless of whether the final level is global. This means that TLB invalidations that involve the **ASID** require the **ASID** to match such entries to perform the required invalidation.

- Required to apply to stage 2 entries only, then:
  - It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
  - It must apply to caching structures that contain information only from stage 2 translation table entries.
- Required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Whenever translation tables entries associated with a particular **VMID** or **ASID** are changed, the corresponding entries must be invalidated from the TLB to ensure that these changes are visible to subsequent execution, including speculative execution, that uses the changed translation table entries.

Some System register field descriptions state that the effect of the field is permitted to be cached in a TLB. This means that all TLB entries that might be affected by a change of the field must be invalidated whenever that field is changed, to ensure that the effect of the change of that control field is visible to subsequent execution, including speculative execution, that uses that control field. This invalidation is required in addition to, and after, the normal synchronization of the System registers described in [Synchronization requirements for AArch64 System registers on page D7-2191](#), and applies to any stage of address translation that is implemented for the translation regime, and **VMID** and **ASID** as appropriate, that is affected by that control field. A control field that is permitted to be cached in a TLB requires this maintenance even when all stages of address translation are disabled.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see [Cache maintenance requirement created by changing translation table attributes on page D4-2135](#).

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access Flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB invalidation.

Special considerations apply to translation table updates that change the memory type, cacheability, or output address of an entry, see [Using break-before-make when updating translation table entries](#).

### Using break-before-make when updating translation table entries

To avoid possibly creating multiple TLB entries for the same address, and to avoid the effects of TLB caching possibly breaking coherency, ordering guarantees or uniprocessor semantics, or possibly failing to clear the Exclusives monitors, the architecture requires the use of a break-before-make sequence when changing translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation table entries involves any of:

- A change of the memory type.
- A change of the cacheability attributes.
- A change of the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable, including if the DBM bit is set and hardware updates to the dirty bits are enabled.
- A change to the size of block used by the translation system. This applies both:
  - When changing from a smaller size to a larger size, for example by replacing a table mapping with a block mapping in a stage 2 translation table.
  - When changing from a larger size to a smaller size, for example by replacing a block mapping with a table mapping in a stage 2 translation table.
- Creating a global entry when there might be non-global entries in a TLB that overlap with that global entry.

A break-before-make sequence on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a DSB instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a DSB instruction to ensure the completion of that invalidation.
3. Write the new translation table entry, and execute a DSB instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution, and therefore the problems described at the start of this subsection cannot arise.

In ARMv8.1, with the introduction of hardware updates to the translation table entries, the effects of not following the break-before-make rules are extended.

If the break-before-make rules are not followed for changing the translation table entries, the ARMv8.1 architecture permits that the following failures associated with the hardware updates of the translation table entries could occur:

- The Access flag is not set on such a translation table entry despite the fact that the memory location associated with that entry was accessed.
- The AP[2] or S2AP[1] bit is modified by the hardware on such a translation table entry despite the fact that the memory location associated with that entry was not written to.
- The AP[2] or S2AP[1] bit is not modified by the hardware on such a translation table entry despite the fact that the memory location associated with that entry was written to.
- The ordering required between hardware updates to such a translation table entry and stores appearing later in program order is not followed.

## D4.9.2 TLB maintenance instructions

The architecture defines TLB maintenance instructions, that provide the following:

- Invalidate all entries in the TLB.
- Invalidate a single TLB entry by [ASID](#) for a non-global entry.
- Invalidate all TLB entries that match a specified [ASID](#).
- Invalidate all TLB entries that match a specified [VA](#), regardless of the [ASID](#).

Each instruction can be specified as applying only to the PE that executes the instruction, or as applying to all PEs in the same Inner Shareable shareability domain as the PE that executes the instruction.

The following subsections describe these instructions:

- [TLB maintenance instruction syntax on page D4-2122.](#)
- [Operation of the TLB maintenance instructions on page D4-2123.](#)
- [Scope of the A64 TLB maintenance instructions on page D4-2124.](#)
- [Invalidation of TLB entries from stage 2 translations on page D4-2128.](#)
- [Broadcast TLB maintenance between AArch32 and AArch64 on page D4-2128.](#)
- [Broadcast TLB maintenance with different translation granule sizes on page D4-2130.](#)
- [Ordering and completion of TLB maintenance instructions on page D4-2130.](#)
- [TLB maintenance in the event of TLB conflict on page D4-2131.](#)
- [The interaction of TLB lockdown with TLB maintenance instructions on page D4-2131.](#)

[TLB maintenance instructions on page C5-320](#) describes the encoding of the TLB maintenance instructions.

## TLB maintenance instruction syntax

The A64 syntax for TLB maintenance instructions is:

TLBI <operation>{, <Xt>}

Where:

<operation> Is one of ALLE1, ALLE2, ALLE3, ALLE1IS, ALLE2IS, ALLE3IS, VMALLE1, VMALLE1IS, VMALLS12E1, VMALLS12E1IS, ASIDE1, ASIDE1IS, VA{L}E1, VA{L}E2, VA{L}E3, VA{L}E1IS, VA{L}E2IS, VA{L}E3IS, VAA{L}E1, VAA{L}E1IS, IPAS2{L}E1, or IPAS2{L}E1IS.

<operation> has a structure of <type><level>{IS} where:

<type> Is one of:

ALL All translations used at <level>.

For the scope of ALL instructions see [ALL on page D4-2124](#).

The ALL instructions are valid for all values of <level>.

VMALL All stage 1 translations used at <level> with the current VMID, if appropriate.

For the scope of the VMALL instructions see [VMALL on page D4-2125](#).

The VMALL instructions are valid only when level == E1.

VMALLS12 All stage 1 and stage 2 translations used at EL1 with the current VMID, if appropriate.

For the scope of the VMALLS12 instructions see [VMALLS12 on page D4-2125](#).

The VMALLS12 instructions are valid only when level == E1.

ASID All translations used at EL1 with the supplied ASID.

For the scope of the ASID instructions see [ASID on page D4-2125](#).

The ASID instructions are valid only when level == E1.

VA{L} Translations used at <level> for the specified address and, if appropriate, the specified ASID.

For the scope of the VA instructions see [VA on page D4-2126](#). For the scope of the VAL instructions see [VAL on page D4-2126](#).

The VA{L} instructions are valid for all values of <level>.

VAA{L} Translations used at <level> for the specified address, for all ASID values, if appropriate.

For the scope of the VAA instructions see [VAA on page D4-2126](#). For the scope of the VAAL instructions see [VAAL on page D4-2126](#).

The VAA{L} instructions are valid only when level == E1.

IPAS2{L} Translations used at <level> for the specified IPA that are held in stage 2 only caching structures.

For the scope of the IPAS2 instructions see [IPAS2 on page D4-2127](#). For the scope of the IPAS2L instructions see [IPAS2L on page D4-2127](#)

The IPAS2{L} instructions are valid only when level == E1.

In the VA{L}, VAA{L}, and IPAS2{L} types:

L An optional parameter that indicates that the invalidation only applies to caching of entries returned from the final lookup level of the translation table walk.

<level> Defines the Exception level of the translation regime that the invalidation applies to. Is one of:

E1 EL1.

E2 EL2.

E3 EL3.

An instruction that applies to the translation regime of an Exception level higher than the Exception level at which the instruction is executed is UNDEFINED.

TLBI ALLE1{IS}, TLBI IPAS2{L}E1{IS} and TLBI VMALLS12E1{IS} are UNDEFINED at EL1.

———— **Note** ————

All TLB maintenance instructions are UNDEFINED at EL0.

IS When present, it indicates that the function applies to all TLBs in the Inner Shareable shareability domain.

<Xt> Passes one or both of an address and an **ASID** as an argument, where required. <Xt> is required for the TLB ASID, TLB VA{L}, TLB VAA{L}, and TLB IPAS2{L} instructions.

If EL2 is not implemented, the TLBI VA{L}E2, TLBI VA{L}E2IS, TLBI ALLE2, and TLBI ALLE2IS instructions are UNDEFINED.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds a **VA**, an **ASID**, or both, use the following register argument format:

**Bits[63:48]** ASID. These bits are RES0 if the instruction does not require an **ASID** argument.

**Bits[47:44]** RES0.

**Bits[43:0]** **VA**[55:12]. For an instruction that requires a **VA** argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:

**4KB granule size** All bits are valid and used for the invalidation.

**16KB granule size** Bits[1:0] RES0 and ignored when the instruction is executed, because **VA**[13:12] have no effect on the operation of the instruction.

**64KB granule size** Bits[3:0] are RES0 and ignored when the instruction is executed, because **VA**[15:12] have no effect on the operation of the instruction.

These bits are RES0 if the instruction does not require a **VA** argument.

For TLB maintenance instructions that take an address argument, hardware interprets **VA**[63:56] as each having the same value as **VA**[55].

If a TLB maintenance instruction targets a translation regime that is using AArch32, meaning the **VA** is only 32-bit, then software must treat **VA**[55:32] as RES0, and these bits are ignored when the instruction is executed.

If the implementation supports 16 bits of **ASID** then the upper 8 bits of the **ASID** are RES0 when the context being invalidated only uses 8 bits.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds an **IPA**, use the following register argument format:

**Bits[63:36]** RES0.

**Bits[35:0]** **IPA**[47:12]. For an instruction that requires a **VA** argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:

**4KB granule size** All bits are valid and used for the invalidation.

**16KB granule size** Bits[1:0] RES0 and ignored when the instruction is executed, because **IPA**[13:12] have no effect on the operation of the instruction.

**64KB granule size** Bits[3:0] are RES0 and ignored when the instruction is executed, because **IPA**[15:12] have no effect on the operation of the instruction.

## Operation of the TLB maintenance instructions

Any TLB maintenance instruction can affect any TLB entries that are not locked down.

The TLB maintenance instructions specify the Exception level of the translation regime to which they apply.

———— **Note** ————

Because there is no guarantee that an unlocked TLB entry remains in the cache, architecturally it is not possible to tell whether a TLB maintenance instruction has affected any TLB entries that were not specified by the instruction.

If a TLB maintenance instruction specifies a VA, and a data or instruction access to that VA would generate an MMU abort, the TLB maintenance instruction does not generate an abort. VAs for which a TLB maintenance instruction does not generate an abort include VAs that are not in the range of VAs that can be translated.

When EL3 is implemented:

- The TLB maintenance instructions that apply to the EL1&0 translation regime take account of the current Security state, as part of the address translation required for the TLB operation.
- SCR\_EL3.NS modifies the effect of the TLB maintenance instructions as follows:
  - For instructions that apply to the EL1&0 translation regime, the SCR\_EL3.NS bit identifies whether the maintenance instructions apply to the Secure or Non-secure EL1&0 translation regime.

———— **Note** ————

If EL3 is not implemented, then there is only a single EL1&0 translation regime.

- For instructions that apply to the EL2 translation regime, or to the EL2&0 translation regime, the SCR\_EL3.NS bit must be 1 or the instruction is UNDEFINED.
- For instructions that apply to the EL3 translation regime, the SCR\_EL3.NS bit has no effect.

———— **Note** ————

- An address-based TLB maintenance instruction that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the instruction.
- Previous versions of the ARM architecture included TLB maintenance instructions that operated only on instruction TLBs, or only on data TLBs. From the introduction of ARMv7, ARM deprecated any use of these instructions. In ARMv8:
  - AArch64 state does not include any of these instructions.
  - AArch32 state includes some of these instructions, but ARM deprecates their use.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, when a TLB maintenance instruction is executed, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

———— **Note** ————

The Contiguous bit does not affect the minimum size of entry that must be invalidated from the TLB

## Scope of the A64 TLB maintenance instructions

The TLB invalidation instruction <type> affects the different possible cached entries in the TLB as follows:

ALL            The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with the state specified by SCR\_EL3.NS.

For entries from the Non-secure EL1&0 translation regime, ALL applies to entries with any VMID.

For entries from a translation regime for which an ASID is valid, the invalidation applies to:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

———— **Note** ————

This means the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

VMALL	<p>The invalidation applies to all cached copies of the stage 1 translation table entries, from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:</p> <ul style="list-style-type: none"> <li>• The Security state specified by <a href="#">SCR_EL3.NS</a>.</li> <li>• For the Non-secure EL1&amp;0 translation regime, the current <a href="#">VMID</a>.</li> </ul> <p>For entries from a translation regime for which an <a href="#">ASID</a> is valid that meet the other specified conditions, the invalidation applies to:</p> <ul style="list-style-type: none"> <li>• All entries above the final level of lookup.</li> <li>• All entries at the final level of lookup.</li> </ul> <p style="text-align: center;"><b>———— Note ————</b></p> <p>This means the invalidation applies to both:</p> <ul style="list-style-type: none"> <li>— Global entries.</li> <li>— Non-global entries with any <a href="#">ASID</a>.</li> </ul> <hr/> <p>VMALL is valid for:</p> <ul style="list-style-type: none"> <li>• EL1.</li> <li>• EL2, when <a href="#">HCR_EL2</a>.{E2H, TGE} is {1, 1}.</li> </ul>
VMALLS12	<p>The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:</p> <ul style="list-style-type: none"> <li>• The Security state specified by <a href="#">SCR_EL3.NS</a>.</li> <li>• For the Non-secure EL1&amp;0 translation regime, the current <a href="#">VMID</a>.</li> </ul> <p>For entries from a translation regime for which an <a href="#">ASID</a> is valid that meet the other specified conditions, the invalidation applies to:</p> <ul style="list-style-type: none"> <li>• All entries above the final level of lookup.</li> <li>• All entries at the final level of lookup.</li> </ul> <p style="text-align: center;"><b>———— Note ————</b></p> <p>This means the invalidation applies to both:</p> <ul style="list-style-type: none"> <li>— Global entries.</li> <li>— Non-global entries with any <a href="#">ASID</a>.</li> </ul> <hr/> <p>VMALLS12 is valid for:</p> <ul style="list-style-type: none"> <li>• EL1.</li> <li>• EL2, when <a href="#">HCR_EL2</a>.{E2H, TGE} is {1, 1}.</li> </ul>
	<p>If EL2 is not implemented, or if the TLBI VMALLS12 instruction is executed when the value of <a href="#">SCR_EL3.NS</a> is 0, the instruction is not UNDEFINED but it has the same effect as TLBI VMALL. This is because there are no stage 2 translations to invalidate.</p>
ASID	<p>The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:</p> <ul style="list-style-type: none"> <li>• The Security state specified by <a href="#">SCR_EL3.NS</a>.</li> <li>• For the Non-secure EL1&amp;0 translation regime, the current <a href="#">VMID</a>.</li> </ul> <p>For entries from a translation regime for which an <a href="#">ASID</a> is valid that meet the other specified conditions, the invalidation applies only if either:</p> <ul style="list-style-type: none"> <li>• The entry is from a level of lookup above the final level and matches the specified <a href="#">ASID</a>.</li> <li>• The entry is a non-global entry from the final level of lookup and matches the specified <a href="#">ASID</a>.</li> </ul> <p>ASID is valid for:</p> <ul style="list-style-type: none"> <li>• EL1.</li> <li>• EL2, when <a href="#">HCR_EL2</a>.{E2H, TGE} is {1, 1}.</li> </ul>

VA	<p>The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:</p> <ul style="list-style-type: none"> <li>• The Security state specified by <a href="#">SCR_EL3.NS</a>.</li> <li>• For the Non-secure EL1&amp;0 translation regime, the current <a href="#">VMID</a>.</li> </ul> <p>For entries from a translation regime for which an <a href="#">ASID</a> is valid that meet the other specified conditions, the invalidation applies only if one of the following applies:</p> <ul style="list-style-type: none"> <li>• The entry is from a level of lookup above the final level and matches the specified <a href="#">ASID</a>.</li> <li>• The entry is a global entry from the final level of lookup.</li> <li>• The entry is a non-global entry from the final level of lookup that matches the specified <a href="#">ASID</a>.</li> </ul>
VAL	<p>The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level, that would be used with all of:</p> <ul style="list-style-type: none"> <li>• The Security state specified by <a href="#">SCR_EL3.NS</a>.</li> <li>• For the Non-secure EL1&amp;0 translation regime, the current <a href="#">VMID</a>.</li> </ul> <p>For entries from a translation regime for which an <a href="#">ASID</a> is valid that meet the other specified conditions, the invalidation applies only if either:</p> <ul style="list-style-type: none"> <li>• The entry is a global entry from the final level of lookup.</li> <li>• The entry is a non-global entry from the final level of lookup that matches the specified <a href="#">ASID</a>.</li> </ul>
VAA	<p>The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:</p> <ul style="list-style-type: none"> <li>• The Security state specified by <a href="#">SCR_EL3.NS</a>.</li> <li>• For the Non-secure EL1&amp;0 translation regime, the current <a href="#">VMID</a>.</li> </ul> <p>For entries from a translation regime for which an <a href="#">ASID</a> is valid that meet the other specified conditions, the invalidation applies to all of:</p> <ul style="list-style-type: none"> <li>• All entries above the final level of lookup.</li> <li>• All entries at the final level of lookup.</li> </ul> <p style="text-align: center;"><b>————— Note —————</b></p> <p>This means the invalidation applies to both:</p> <ul style="list-style-type: none"> <li>— Global entries.</li> <li>— Non-global entries with any <a href="#">ASID</a>.</li> </ul>
VAAI	<p>The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:</p> <ul style="list-style-type: none"> <li>• The Security state specified by <a href="#">SCR_EL3.NS</a>.</li> <li>• For the Non-secure EL1&amp;0 translation regime, the current <a href="#">VMID</a>.</li> </ul> <p>For entries from a translation regime for which an <a href="#">ASID</a> is valid that meet the other specified conditions, the invalidation applies to all entries at the final level of lookup.</p> <p style="text-align: center;"><b>————— Note —————</b></p> <p>This means the invalidation applies to both:</p> <ul style="list-style-type: none"> <li>• Global entries.</li> <li>• Non-global entries with any <a href="#">ASID</a>.</li> </ul>

- IPAS2** The invalidation applies to all cached copies of the stage 2 translation table entries from any level of the translation table walk required to translate the specified [IPA](#), that both:
- Are held in TLB caching structures holding stage 2 only entries.
  - Would be used with the current [VMID](#).
- It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.
- The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.
- When executed with the [SCR\\_EL3.NS](#)=0, or in an implementation that does not implement EL2, this instruction is a NOP.
- For more information about the architectural requirements for the IPAS2 instruction see [Invalidation of TLB entries from stage 2 translations on page D4-2128](#).
- IPAS2L** The invalidation applies to cached copies of the stage 2 translation table entry from the final level of the stage 2 translation table walk required to translate the specified [IPA](#), that both:
- Are held in TLB caching structures holding stage 2 only entries.
  - Would be used with the current [VMID](#).
- It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.
- The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.
- When executed with the [SCR\\_EL3.NS](#)=0, or in an implementation that does not implement EL2, this instruction is a NOP.
- For more information about the architectural requirements for the IPAS2L instruction see [Invalidation of TLB entries from stage 2 translations on page D4-2128](#).

The entries that the invalidations apply to are not affected by the state of any other control bits involved in the translation process. Therefore, the following is a non-exhaustive list of control bits that do not affect how a TLB maintenance instruction updates the TLB entries:

**In AArch64 state**

[SCTLR\\_EL1.M](#), [SCTLR\\_EL2.M](#), [SCTLR\\_EL3](#).{M, RW}, [HCR\\_EL2](#).{VM, RW},  
[TCR\\_EL1](#).{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}, [TCR\\_EL2](#).{TG0, T0SZ},  
[TCR\\_EL3](#).{TG0, T0SZ}, [VTCR\\_EL2](#).{SL0, T0SZ}, [TTBR0\\_EL1](#).ASID, [TTBR1\\_EL1](#).ASID.

**In AArch32 state**

[SCTLR.M](#), [HCR.VM](#), [TTBCR](#).{EAE, PD1, PD0, N, EPD1, T1SZ, EPD0, T0SZ, A1},  
[HTCR](#).T0SZ, [VTCR](#).{SL0, T0SZ}, [TTBR0](#).ASID, [TTBR1](#).ASID, [CONTEXTIDR](#).ASID.

———— **Note** ————

- ARM expects most TLB maintenance performed by an operating system to occur to the last level entries of the stage 1 translation table walks, and the purpose of the address-based TLB invalidation instructions where the invalidation need only apply to caching of entries returned from the last level of translation table walk of stage 1 translation is to avoid unnecessary loss of the intermediate caching of the translation table entries. Similarly, for stage 2 translations ARM expects that most TLB maintenance performed by a hypervisor for a given Guest operation system will affect only the last level entries of the stage 2 translations. Therefore, similar capability is provided for instructions that invalidate single stage 2 entries.
- The architecture permits the invalidation of entries in TLB caching structures at any time, so for each of these instructions the definition is in terms of the minimum set of entries that must be invalidated from TLB caching structures, and an implementation might choose to invalidate more entries. In general, for best performance, ARM recommends not invalidating entries that are not required to be invalidated.

- Dependencies on the [VMID](#) for the Non-secure EL1&0 translation regime apply even when [HCR\\_EL2.VM](#) is set to 0. Because the architecture does not require the [VTTBR\\_EL2.VMID](#) field to be reset in hardware, the reset routine of each active PE must initialize [VTTBR\\_EL2.VMID\[7:0\]](#) to a common value such as 0, even if stage 2 translation is not in use.
- 

## Invalidation of TLB entries from stage 2 translations

The architectural requirements of the IPAS2 instruction are that:

1. The following code is sufficient to invalidate all cached copies of the stage 2 translation of the [IPA](#) held in Xt for the current [VMID](#), with the corresponding requirement for the broadcast versions of the instructions:

```
TLBI IPAS2E1, Xt
DSB
TLBI VMALLE1
```

2. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the [IPA](#) held in Xt used to translate the [VA](#) (and the specified [ASID](#) when executing TLBI VAE1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:

```
TLBI IPAS2E1, Xt
DSB
TLBI VAE1, Xt2 ; or TLBI VAAE1, Xt2
```

3. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the [IPA](#) held in Xt used to translate the [IPA](#) produced by the last level of stage 1 translation table lookup for the [VA](#) (and [ASID](#) when executing TLBI VALE1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:

```
TLBI IPAS2E1, Xt
DSB
TLBI VALE1, Xt2 ; or TLBI VAALE1, Xt2
```

---

### Note

Depending on the invalidation required, software must use the entire sequence 1, 2, or 3, even when Non-secure EL1&0 stage 1 translation is disabled.

---

Equivalent architectural requirements apply to the IPAS2L instruction, except that the only TLB entries that must be invalidated by an IPAS2L instruction are those that come from the final level of the translation table lookup.

## Broadcast TLB maintenance between AArch32 and AArch64

In most cases, a TLB maintenance instruction affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch64 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch32, provided that the address, qualify the scope of the [ASID](#) and [VMID](#) matching requirements of the original instruction are met, as specified in [Scope of the A64 TLB maintenance instructions on page D4-2124](#).

---

### Note

The requirement to match means that the invalidation only occurs on the PE that is using AArch32 if, for the PE that executed the TLB maintenance instruction at an Exception level that is using AArch64, both of the following apply:

- If [VA](#) matching is required, the [VA](#) is 0x0000FFFFFFFF or lower in the memory map.
  - If [ASID](#) matching is required and the PE is using a 16-bit [ASID](#), then the top 8 bits of the [ASID](#) are zero.
-

Except for the cases identified here, a TLB maintenance instructions affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch32 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch64, provided that the address, [ASID](#), and [VMID](#) matching requirements of the original instruction are met, as specified in [Scope of the A64 TLB maintenance instructions on page D4-2124](#). In addition, for the instruction executed in AArch32 state:

- For a TLBIMVAAIS, TLBIMVAALIS, TLBIMVAHIS, TLBIMVAIS, TLBIMVALHIS, or TLBIMVALIS instruction, the [VA](#) supplied as an argument is zero-extended.
- For a TLBIIPAS2IS or TLBIIPAS2LIS instruction, the [IPA](#) supplied as an argument is zero-extended.
- For a TLBIASIDIS, TLBIMVAIS, or TLBIMVALIS instruction, the [ASID](#) supplied as an argument is zero-extended if the PE executing in AArch64 state is using a 16-bit [ASID](#).

The [VA](#) from the instruction executed in AArch32 state is zero-extended, and the [ASID](#) is zero-extended if the PE executing in AArch64 state is using a 16-bit [ASID](#).

The exceptions to these general rules are as follows:

1. An ARMv7 PE in the same Inner Shareable domain is treated in the same way as an ARMv8 PE for which EL3 is using AArch32, except that if an ARMv8 PE issues a broadcast instruction that is not defined in ARMv7, then that instruction is not required to have an effect on the TLBs of the ARMv7 PE. The instructions that do not exist in ARMv7 include the following TLB maintenance instructions that ARMv8 adds to the T32 and A32 instruction sets:
  - The following instructions that operate on TLB entries for the final level of translation table walk for stage 1 translations:  
TLBIMVALIS, TLBIMVAALIS, TLBIMVALHIS, TLBIMVAL, TLBIMVAAL, and TLBIMVALH.
  - The following instructions that operate by [IPA](#) on TLB entries for stage 2 translations:  
TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, and TLBIIPAS2L.
2. The number of Exception levels in Secure state depends on whether EL3 is using AArch32 or EL3 is using AArch64. This means that, within the Inner Shareable domain, there might be PEs with different numbers of Exception levels in Secure state. Therefore, the following exceptions are made to the general rules:
  - If a PE with EL3 using AArch32 issues a broadcast AArch32 TLB maintenance instruction affecting Secure entries, and the Inner Shareable domain also contains PEs with EL3 using AArch64, then the architecture does not require that the broadcast AArch32 TLB maintenance instruction has any effect on either:
    - The EL3 translation regime of the PEs with EL3 using AArch64.
    - The Secure EL1&0 translation regime of the PEs with EL3 using AArch64, regardless of whether the Secure EL1&0 translation regime is using AArch64 or AArch32.
  - If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting EL3 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32, then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.
  - If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting Secure EL1 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32 then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.

#### ———— **Note** ————

While the exceptions to the general rule mean the architecture does not require the specified TLB invalidations, the architecture also does not require that entries in the TLB remain in the TLB at any time, and so it is permissible that such broadcast instructions affect these translation regimes.

## Broadcast TLB maintenance with different translation granule sizes

In the following cases, a broadcast TLB maintenance instruction is not required to perform any invalidation on the recipient PE:

- The TLB maintenance instruction specifying a **VA** and affecting the EL2 translation regime, the EL2&0 translation regime, or the EL3 translation regime is broadcast from a PE using one translation granule size for that translation regime to a PE using a different translation granule size for that same translation regime
- The TLB maintenance instruction specifying a **VA** and affecting the EL1&0 translation regime is broadcast from a PE using one stage 1 translation granule size for that translation regime for a particular **ASID** (if applicable), **VMID** (if applicable), and Security state, to a PE where EL1 for the same **ASID** (if applicable), **VMID** (if applicable), and Security state, is using a different stage 1 translation granule size.
- The TLB maintenance instruction specifying a **VA** and affecting the Non-secure EL1&0 translation regime is broadcast from a PE using one stage 2 translation granule size for a particular **ASID** (if applicable) and **VMID**, to a PE where EL1 for the same **ASID** (if applicable) and **VMID** is using a different stage 2 translation granule size.
- The TLB maintenance instruction specifying an **IPA** and affecting the Non-secure EL1&0 translation regime is broadcast from a PE using one stage 2 translation granule size for a particular **VMID** to a PE where EL1 for the same **VMID** is using a different stage 2 translation granule size.

## Ordering and completion of TLB maintenance instructions

For AArch64 execution, a TLB maintenance instruction can be executed in any order relative to:

- Any load or store instruction, unless a DSB is executed between the load or store and the TLB maintenance instruction.

### ———— **Note** ————

In the ARM architecture, a translation table walk is considered to be a separate observer, and a store to the translation tables can be observed by that separate observer at any time after the instruction has been executed, but is only guaranteed to be observable after the execution of a DSB instruction by the PE that executed the store to the translation tables.

- Another TLB maintenance instruction, unless a DSB is executed between the instructions.
- A data or instruction cache maintenance instruction, unless a DSB is executed between the instructions.

For AArch64 execution, the completion rules are:

- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated have been observed by all observers, to the extent that those accesses must be observed. The shareability and cacheability of the accessed memory locations determine the extent to which the accesses must be observed.

### ———— **Note** ————

For TLB maintenance instructions that affect other PEs, the memory accesses from those PEs that used the TLB entries that have been invalidated are included in the set of memory accesses that must have been observed when the TLB maintenance instruction is complete.

After the TLB invalidate instruction is complete, no new memory accesses using the invalidated TLB entries will be observed by those observers.

### ———— **Note** ————

This requirement does not mean that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.

- A TLB maintenance instruction can complete at any time after it is issued, but is only guaranteed to be complete after the execution of DSB by the PE that executed the TLB maintenance instruction.
- The effects of a completed TLB maintenance instruction are only guaranteed to be visible on the PE that executed the instruction after the execution of a [Context synchronization event](#) by the PE that executed the TLB maintenance instruction.

In all cases in this section where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores. A DSB NSH is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE. A DSB ISH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

### TLB maintenance in the event of TLB conflict

In the event that multiple entries in the TLB are being used to translate a given address (which implies that an attempt to access the given address might give rise to a TLB Conflict abort), it is IMPLEMENTATION DEFINED as to the form of TLB maintenance operation that the software must perform in order to be guaranteed that all TLB entries associated with the given address and translation regime have been invalidated. In all cases, an ALL or VMALL form of TLB maintenance operation that targets the given translation regime is guaranteed to remove all entries within that regime, even if there are multiple, conflicting TLB entries for any given address within that regime.

### The interaction of TLB lockdown with TLB maintenance instructions

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on a locked TLB entry of a TLB invalidate all operation that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  - The operation has no effect on entries that are locked down.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down.  
Any such exceptions taken from Non-secure EL1 can be trapped to EL2, see [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1857](#).

#### ———— Note —————

These options permit a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.

- The effect on a locked TLB entry of a TLB invalidate by VA or invalidate by ASID match operation that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  - The locked entry is invalidated in the TLB.
  - The operation has no effect on any locked entry in the TLB. In the case of an invalidate single entry by VA, this means the PE treats the operation as a NOP.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down.

The exception syndrome definitions include a fault code for cache and TLB lockdown faults, see [ESR\\_EL1, Exception Syndrome Register \(EL1\) on page D7-2249](#).

#### ———— Note —————

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling the effect of TLB maintenance instructions on entries that can be locked down but are not actually locked down must provide an IMPLEMENTATION DEFINED mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see [The interaction of cache lockdown with cache maintenance instructions on page D3-1995](#).

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of any TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

### D4.9.3 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the [VMID](#) or [ASID](#) that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```
; Change control bits in System registers
ISB          ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that maintenance requirement applies to are:

- Any change to the [MAIR\\_EL1](#), [MAIR\\_EL2](#), or [MAIR\\_EL3](#) registers.
- Any change to the [AMAIR\\_EL1](#), [AMAIR\\_EL2](#), or [AMAIR\\_EL3](#) registers.
- Any change to [SCTLR\\_EL1.EE](#), [SCTLR\\_EL2.EE](#), or [SCTLR\\_EL3.EE](#).
- Any change to [SCTLR\\_EL1.WXN](#), [SCTLR\\_EL2.WXN](#), or [SCTLR\\_EL3.WXN](#).
- Any change to any of the [SCR\\_EL3](#).{RW, SIF} bits.
- Any change to any of the [HCR\\_EL2](#).{RW, DC, PTW, VM} bits. See also [Changing HCR\\_EL2.PTW](#).
- Any changes to the registers that control address translation:
  - Any change to any of the [TCR\\_EL1](#), [TCR\\_EL2](#), [TCR\\_EL3](#), or [VTCR\\_EL2](#) registers.
  - Any change to the [TTBR0\\_EL1](#), [TTBR1\\_EL1](#), [TTBR1\\_EL2](#), [TTBR0\\_EL2](#), [TTBR0\\_EL3](#), or [VTTBR\\_EL2](#) registers.

#### Changing HCR\_EL2.PTW

When the value of the Protected table walk bit, [HCR\\_EL2.PTW](#), is 1, a stage 1 translation table access in the Non-secure EL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular [VMID](#) might hold entries that depend on the effect of [HCR\\_EL2.PTW](#). Therefore, if the value of [HCR\\_EL2.PTW](#) is changed without a change to the [VMID](#) value, all TLB entries associated with the current [VMID](#) must be invalidated before executing software at Non-secure EL1 or EL0. If this is not done, behavior is CONSTRAINED UNPREDICTABLE, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6120](#).

## D4.10 Caches in a VMSAv8-64 implementation

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

In particular, maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

- Summarizes the architectural requirements for the interaction between caches and address translation.
- Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

- [Data and unified caches](#).
- [Instruction caches](#).

In addition, [Cache maintenance requirement created by changing translation table attributes on page D4-2135](#) describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see [A64 Cache maintenance instructions on page D3-1985](#), that describes the cache maintenance instructions in the A64 instruction set.

### D4.10.1 Data and unified caches

For data and unified caches, the use of address translation is entirely transparent to any data access other than as described in [Mismatched memory attributes on page B2-118](#).

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as *Physically-indexed, physically-tagged* (PIPT) caches.

### D4.10.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture permits different behaviors for instruction caches. These are identified by descriptions of the associated expected implementation. The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of address translation transparent to the instruction cache:

- [PIPT \(Physically-indexed, physically-tagged\) instruction caches on page D4-2134](#).
- [VPIPT \(VMID-aware PIPT\) instruction caches on page D4-2134](#).
- [VIPT \(Virtually-indexed, physically-tagged\) instruction caches on page D4-2134](#).
- [The IVIPT Extension on page D4-2135](#).

The CTR\_EL0.L1Ip field identifies the form of the instruction caches.

---

**Note**

---

For software to be portable between implementations that might use any of PIPT instruction caches, VPIPT instruction caches, or VIPT instruction caches, software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

---

### **PIPT (*Physically-indexed, physically-tagged*) instruction caches**

For a PIPT instruction cache:

- The use of memory address translation is entirely transparent to all instruction fetches other than as described in *Mismatched memory attributes* on page B2-118.
- If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see *The IVIPT Extension* on page D4-2135.

### **VPIPT (*VMID-aware PIPT*) instruction caches**

An implementation that includes ARMv8.2-VPIPT can implement VPIPT instruction caches.

For a VPIPT instruction cache:

- Instruction fetches from Non-secure EL1 and Non-secure EL0 are only permitted to hit in the cache if the instruction fetch is made using the VMID that was used when the entry in the instruction cache was fetched.
- An instruction cache maintenance instruction executed at Non-secure EL0 or at Non-secure EL1 is required to have an effect on entries in the instruction cache only if those entries were fetched using the VMID that is current when the cache maintenance instruction is executed.

All other requirements for the use of cache maintenance instructions are the same as for *PIPT (Physically-indexed, physically-tagged) instruction caches*.

An implementation that provides VPIPT instruction caches implements the IVIPT Extension, see *The IVIPT Extension* on page D4-2135.

### **VIPT (*Virtually-indexed, physically-tagged*) instruction caches**

For a VIPT instruction cache:

- The use of memory address translation is transparent to all instruction fetches other than for the effect of memory address translation on instruction cache invalidate by address operations or as described in *Mismatched memory attributes* on page B2-118.

---

**Note**

---

Cache invalidation is the only cache maintenance that can be performed on an instruction cache.

---

- If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the VA supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a PA from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see *The IVIPT Extension* on page D4-2135.

## The IVIPT Extension

In ARMv8, any permitted instruction cache implementation can be described as implementing the *IVIPT Extension* to the ARM architecture.

The formal definition of the ARM IVIPT Extension is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a [PA](#) that holds an instruction.

---

### Note

---

Previous versions of the ARM architecture have permitted an instruction cache option that does not implement the ARM IVIPT Extension.

---

## D4.10.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in [General TLB maintenance requirements on page D4-2119](#). If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through
- Write-Back to Non-cacheable
- Write-Through to Non-cacheable
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the shareability attributes to the required new values.

# Chapter D5

## The Performance Monitors Extension

This chapter describes the ARMv8 implementation of the ARM Performance Monitors, that are an optional non-invasive debug component. It describes version 3 of the *Performance Monitor Unit* (PMU) architecture, PMUv3. It contains the following sections:

- [About the Performance Monitors on page D5-2138.](#)
- [Accuracy of the Performance Monitors on page D5-2140.](#)
- [Behavior on overflow on page D5-2142.](#)
- [Attributability on page D5-2144.](#)
- [Effect of EL3 and EL2 on page D5-2145.](#)
- [Event filtering on page D5-2147](#)
- [Performance Monitors and Debug state on page D5-2149.](#)
- [Counter enables on page D5-2150.](#)
- [Counter access on page D5-2151.](#)
- [Events, event numbers, and mnemonics on page D5-2152.](#)
- [Performance Monitors Extension registers on page D5-2176.](#)

---

**Note**

[Table K11-1 on page K11-6282](#) disambiguates the general register references used in this chapter.

---

## D5.1 About the Performance Monitors

In ARMv8-A, the Performance Monitors Extension is an OPTIONAL feature of an implementation, but ARM strongly recommends that ARMv8-A implementations include version 3 of the Performance Monitors Extension, PMUv3.

---

**Note**

No previous versions of the Performance Monitors Extension can be implemented in ARMv8.

---

The basic form of the Performance Monitors is:

- A 64-bit cycle counter, see [Time as measured by the Performance Monitors cycle counter on page D5-2139](#).
- A number of 32-bit event counters. The event counted by each counter is programmable. ARMv8 provides space for up to 31 counters. The actual number of counters is IMPLEMENTATION DEFINED, and the specification includes an identification mechanism.

---

**Note**

ARM recommends that at least two counters are implemented, and that hypervisors provide at least this many counters to guest operating systems.

---

- When EL2 is implemented, the required controls to partition the implemented counters into the following sets:
  - A set which is available for use by the guest operating system.
  - A set which is available for use by the hypervisor.
- Controls for:
  - Enabling and resetting counters.
  - Flagging overflows.
  - Enabling interrupts on overflow.

Monitoring software can enable the cycle counter independently of the event counters.

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures.

---

**Note**

Implementations that include PMUv3 must, as a minimum requirement, implement a subset of the common events. See [Common event numbers on page D5-2156](#).

---

- Reserves a large event number space for IMPLEMENTATION DEFINED events.

The full set of events for an implementation is IMPLEMENTATION DEFINED. ARM recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation.

When an implementation includes the Performance Monitors Extension, ARMv8 defines the following possible interfaces to the Performance Monitors Extension registers:

- A System register interface. This interface is mandatory.

---

**Note**

In AArch32 state, the interface is in the (coproc==0b1111) encoding space.

---

- An external debug interface which optionally supports memory-mapped accesses. Implementation of this interface is OPTIONAL. See [Chapter 12 Recommended External Interface to the Performance Monitors](#).

An operating system can use the System registers to access the counters.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:

- A set of events, from which a selection can be exported onto a bus for use as external events.
- The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

The Performance Monitors Extension is common to AArch64 operation and AArch32 operation. This means the ARMv8 architecture defines both AArch64 and AArch32 System registers to access the Performance Monitors. For example, the Performance Monitors Cycle Count Register is accessible as:

- When executing in AArch64 state, [PMCCNTR\\_EL0](#), see [PMCCNTR\\_EL0, Performance Monitors Cycle Count Register on page D7-2633](#).
- When executing in AArch32 state, [PMCCNTR](#), see [PMCCNTR, Performance Monitors Cycle Count Register on page G6-5335](#).

### D5.1.1 Time as measured by the Performance Monitors cycle counter

The Performance Monitors cycle counter, accessed through [PMCCNTR\\_EL0](#) or [PMCCNTR](#), increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

#### ————— Note —————

- This means that, in an implementation where PEs are multithreaded, the counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.
- Although the architecture requires that direct reads of [PMCCNTR\\_EL0](#) or [PMCCNTR](#) occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

The architecture requires that an indirect write to the [PMCCNTR\\_EL0](#) or [PMCCNTR](#) is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

### D5.1.2 Interaction with trace

It is IMPLEMENTATION DEFINED whether the implementation exports counter events to a Trace macrocell, or other external monitoring agent, to provide triggering information. The form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting might be enabled as part of the performance monitoring control functionality.

ARM recommends system designers include a mechanism for importing a set of external events to be counted, but such a feature is IMPLEMENTATION DEFINED. When implemented, this feature enables the Trace macrocell to pass in events to be counted.

### D5.1.3 Interaction with power saving operations

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.

## D5.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See [Non-invasive behavior](#).
- Must provide broadly accurate and statistically useful count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See [A reasonable degree of inaccuracy on page D5-2141](#).
- IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to put the PE in an operating state that might do one or both of the following:
  - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
  - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

### D5.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug feature. A non-invasive debug feature permits the observation of data and program flow. Performance Monitors, PC Sample-based Profiling and Trace are non-invasive debug features.

Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the processor. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled in a multitasking operating system. As such, a reasonable variation in performance is permissible.

———— **Note** ————

Power consumption is one measure of performance. Therefore, a reasonable variation in power consumption is permissible.

ARM does not define a *reasonable variation in performance*, but recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code that is representative of the application workload.

———— **Note** ————

For profiles other than A-profile, there is the potential for stronger requirements. Ultimately, performance requirements are determined by end-users, and not set by the architecture.

For some common architectural events, this requirement to be non-invasive can conflict with the requirement to present an accurate value of the count under normal operating conditions. Should an implementation require more performance-invasive techniques to accurately count an event, there are the following options:

- If the event is optional, define an alternative IMPLEMENTATION DEFINED event that accurately counts the event and document the impact on performance of enabling the event.
- Provide an IMPLEMENTATION DEFINED control that disables accurate counting of the event to restore broadly accurate performance, and document the impact on performance of accurate counting.

## D5.2.2 A reasonable degree of inaccuracy

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the counts is acceptable. ARM does not define a *reasonable degree of inaccuracy* but recommends the following guidelines:

- Under normal operating conditions, the counters must present an accurate value of the count.
- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the count to be inaccurate.
- Under very unusual, non-repeating pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

### ———— Note ————

An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, it is not reasonable for the count of branch behavior to be inaccurate when caused by a systematic error generated by the loop structure producing a dropping in branch count.

However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the point in a pipeline where the event counter is incremented, relative to the point where a read of the event counters is made. This means that pipelining effects can cause some imprecision.

A change of Security state can also affect the accuracy of the Performance Monitors, see [Interaction with EL3 on page D5-2145](#).

In addition to this, entry to and exit from Debug state can disturb the normal running of the PE, causing further inaccuracy in the Performance Monitors. Disabling the counters while in Debug state limits the extent of this inaccuracy. An implementation can employ methods to limit this inaccuracy, for example by promptly disabling the counters during the Debug state entry sequence.

An implementation must document any particular scenarios where significant inaccuracies are expected.

## D5.3 Behavior on overflow

All events are counted in 32-bit wrapping counters, that overflow when they wrap. The cycle counter, [PMCCNTR](#), is a 64-bit wrapping counter, that is configured by [PMCR.LC](#) to either:

- Signal an overflow when bit [PMCCNTR\[63\]](#) overflows.
- Signal an overflow when bit [PMCCNTR\[31\]](#) overflows into bit [PMCCNTR\[32\]](#).

On a Performance Monitors counter overflow:

- An overflow status bit is set to 1. See [PMOVSCLR](#).
- An interrupt request is generated if the PE is configured to generate counter overflow interrupts. For more information, see [Generating overflow interrupt requests](#).
- The counter continues counting events.

### D5.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See [PMINTENSET](#) and [PMINTENCLR](#).

---

**Note**

- The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.
- ARM recommends that the overflow interrupt requests:
  - Translate into a **PMUIRQ** signal, so that they are observable to external devices.
  - Connect to inputs on an IMPLEMENTATION DEFINED generic interrupt controller as a *Private Peripheral Interrupt* (PPI) for the originating processor. See the *ARM Generic Interrupt Controller Architecture Specification* for information about PPIs.
  - Connect to a *Cross Trigger Interface* (CTI), see [Chapter H5 The Embedded Cross-Trigger Interface](#).
- ARM strongly discourages implementations from connecting overflow interrupt requests from multiple PEs to the same *System Peripheral Interrupt* (SPI) identifier.
- From GICv3, the *ARM® Generic Interrupt Controller Architecture Specification* recommends that the *Private Peripheral Interrupt* (PPI) with ID 23 is used for overflow interrupt requests.

---

Counter overflow when counting one or more events generates an unsigned carry out. Software can write to the counters to control the frequency at which interrupt requests occur. For counters other than the cycle counter, the counter is always a 32-bit unsigned wrapping value. For example, software might set a counter to `0xFFFF0000`, to generate another counter overflow after 65 536 increments, and reset it to this value every time an overflow interrupt occurs.

---

**Note**

If an event can occur multiple times in a single clock cycle, then counter overflow can occur without the counter registering a value of zero.

The overflow interrupt request is a level-sensitive request. The PE signals a request for:

- Any given PMNx counter, when the value of [PMOVSSET\[x\]](#) is 1, the value of [PMINTENSET\[x\]](#) is 1, and one of the following is true:
  - EL2 is not implemented and the value of [PMCR.E](#) is 1.
  - EL2 is implemented,  $x$  is less than the value of [HDCR.HPMN](#), and the value of [PMCR.E](#) is 1.
  - EL2 is implemented,  $x$  is greater than or equal to the value of [HDCR.HPMN](#), and the value of [HDCR.HPME](#) is 1.
- The cycle counter, when the values of [PMOVSSET\[31\]](#), [PMINTENSET\[31\]](#), and [PMCR.E](#) are all 1.

The overflow interrupt request is active in both Secure and Non-secure states. In particular, if EL3 and EL2 are both implemented, overflow events from PMNx where *x* is greater than or equal to the value of [HDCR.HPMN](#) can be signaled from all modes and states but only if the value of [HDCR.HPME](#) is 1.

The interrupt handler for the counter overflow request must cancel the interrupt request, by writing to [PMOVSCLR\[x\]](#) to clear the overflow bit to 0.

### Pseudocode description of overflow interrupt requests

See [Chapter J1 ARMv8 Pseudocode](#) for a pseudocode description of overflow interrupt requests. The [AArch64.CheckForPMUOverflow\(\)](#) and [AArch32.CheckForPMUOverflow\(\)](#) pseudocode functions signal PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface.

## D5.4 Attributability

An event caused by the PE counting the event is Attributable. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:

- The current Security state of the PE.
- The current Exception level of the PE.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

In a multithreaded implementation, an event might be Attributable either to the current Exception level alone, or to both the Exception level and the Security state of another PE with the same values for affinity level 1 and higher.

### ———— Note ————

An implementation is described as multithreaded when the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. In this section, when referring to a multithreaded implementation, *thread* is used to mean processing elements with different affinity level 0 values and the same values for affinity level 1 and higher.

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are Attributable, unless otherwise stated.

Unattributable events might be counted when Attributable events are not counted. See:

- [Interaction with EL3 on page D5-2145](#).
- [Event filtering on page D5-2147](#).
- [Performance Monitors and Debug state on page D5-2149](#).

These sections are summarized by [Table D5-1](#) for events Attributable to the processor, and Unattributable events.

**Table D5-1 Counting events**

Counter and PMU enabled	State	Allowed or prohibited	Filtered	Event type		
				If Attributable to:	Then	Else
Yes	Non-debug	Allowed	Not filtered	X	Count	Count
			Filtered	Current Exception level	Do not count	IMPLEMENTATION DEFINED
		Prohibited	X	Current Security state	Do not count	IMPLEMENTATION DEFINED
	Debug	X	X	Debugger operations or raw cycles	Do not count	IMPLEMENTATION DEFINED
No	X	X	X	X	Do not count	Do not count

## D5.5 Effect of EL3 and EL2

This section describes the effects of implementing EL3 and EL2 on the Performance Monitors. It contains the following subsections:

- [Interaction with EL3](#).
- [Interaction with EL2 on page D5-2146](#).

### D5.5.1 Interaction with EL3

While counting events is never prohibited in Non-secure state, there are some restrictions on counting events in Secure state. From reset, counting events Attributable to Secure state is prohibited in Secure state. When executing in AArch32 state, software can set [SDCR.SPME](#) to 1 to permit event counting in Secure state. In AArch64 state, software can set [MDCR\\_EL3.SPME](#) to 1 to permit event counting in Secure state.

#### ———— Note ————

This enables a Secure Monitor to permit profiling within Secure state without having to configure an IMPLEMENTATION DEFINED debug authentication interface.

The system can use the external authentication interface to override SPME.

If EL3 is not implemented, the behavior is as if the value of [SDCR.SPME](#) or [MDCR\\_EL3.SPME](#) is 1, as appropriate.

Counting Attributable events in Secure state is prohibited unless any one of the following is true:

- EL3 is not implemented.
- EL3 is implemented, is using AArch64, and the value of [MDCR\\_EL3.SPME](#) is 1.
- EL3 is implemented, is using AArch32, and the value of [SDCR.SPME](#) is 1.
- EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0, and the value of [SDER32\\_EL3.SUNIDEN](#) is 1.
- In ARMv8.0 and ARMv8.1 implementations, EL3 is implemented, and counting is permitted by an IMPLEMENTATION DEFINED authentication interface, `ExternalSecureNoninvasiveDebugEnabled() == TRUE`.

#### ———— Note ————

Software can read the Authentication Status register, [DBGAUTHSTATUS](#), to determine the state of an IMPLEMENTATION DEFINED authentication interface.

Software executing at EL3 can trap attempts by lower Exception levels to access the PMU. This means that the Secure monitor can identify any software which is using the PMU and switch contexts, if required.

The cycle counter, [PMCCNTR](#), counts even when event counting is prohibited, unless [PMCR.DP](#) is set to 1 or the PE is in Debug state.

The Performance Monitors registers are always accessible regardless of the values of the authentication signals and the [SDER.SUNIDEN](#) bit. Authentication controls whether the counters count events, it does not control access to the Performance Monitors registers.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when counting Attributable events is prohibited.

#### ———— Note ————

- Additional controls in [PMCR](#), [HDCR](#), [PMCNTENSET](#), and [PMCNTENCLR](#) can also disable the event counters and the cycle counter.
- Controls in [PMEVTYPER<n>](#) and [PMCCFILTR](#) can also disable counting based on Exception level and Security state.

See [AArch64.CountEvents\(\)](#) and [AArch32.CountEvents\(\)](#) in [Chapter J1 ARMv8 Pseudocode](#) for more information. The [CountEvents\(\)](#) functions return TRUE if PMNx counts events or the cycle counter counts cycles at the current Exception level and state. However, these functions do not completely describe the behavior for Unattributable events.

In AArch32 state, the Performance Monitors registers are Common registers, see [Classification of System registers](#) on page G4-4692.

The Performance Monitors are intended to be broadly accurate and statistically useful, see [Accuracy of the Performance Monitors](#) on page D5-2140. Some inaccuracy is permitted at the point of changing Security state, however. To avoid the leaking of information from the Secure state, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.

## Multithreaded implementations

If an implementation is multithreaded and the value of [PMEVTYPER<n>.MT == 1](#), then the PE does not count an event that is Attributable to Secure state on another thread if counting events Attributable to Secure state is prohibited in Secure state on the PE that is counting the events.

### Example D5-1 The effect of having [PMEVTYPER<n>.MT == 1](#)

---

If the value of [MDCR\\_EL3.SPME](#) is 0 on one thread, then it does not count events Attributable to Secure state on another thread, even if one or both of the following applies:

- This thread is in Non-secure state.
- [MDCR\\_EL3.SPME == 1](#) on the other thread.

---

Otherwise:

- When the current configuration prohibits counting of events Attributable to Secure state in Secure state, it is IMPLEMENTATION DEFINED whether:
  - Counting events Attributable to Secure state on this PE in Non-secure state is permitted.
  - Counting Unattributable events related to other secure operations in the system is permitted.
- Otherwise, counting events in Non-secure state is permitted.

## D5.5.2 Interaction with EL2

In an implementation that includes EL2, Non-secure software executing at EL2 can:

- Trap any attempt by the Guest OS to access the PMU. This means the hypervisor can identify which Guest OSs are using the PMU and intelligently employ switching of the PMU state.
- Trap accesses to the [PMCR](#), so that it can fully virtualize the PMU identity registers, [PMCR.IMP](#) and [PMCR.IDCODE](#).
- Reserve the highest-numbered counters for its own use by overriding the value of [PMCR.N](#) seen by the Guest OS. The PE does not permit a Guest OS to access the reserved counters.

[HDCR](#) controls Performance Monitors virtualization.

- [Counter enables](#) on page D5-2150.
- [Counter access](#) on page D5-2151.

## D5.6 Event filtering

The PMU can filter events by various combinations of Exception level and Security state. This gives software the flexibility to count events across multiple processes.

### D5.6.1 Filtering by Exception level and PE state

In AArch64 state:

- For each event counter `PMEVTYPER<n>_EL0` specifies the Exception levels in which the counter counts events Attributable to Exception levels.
- `PMCCFILTR_EL0` specifies the Exception levels in which the cycle counter counts.

In an implementation that supports multithreading:

- When the value of `PMEVTYPER<n>_EL0.MT` is 1, if an event is Attributable to another thread, then the specified filtering applies to the current Exception level and PE state of the thread to which the event is attributable, regardless of the Exception level and state of the counting thread.
- When the value of `PMEVTYPER<n>_EL0.MT` is 0, the event only counts events that are attributable to the counting thread, and the filtering applies to the Exception level and PE state of the counting state, see [Example D5-2](#).

#### Example D5-2 Example of the effect of the `PMEVTYPER<n>_EL0.MT` control

If the value of `PMEVTYPER<n>_EL0.U` is 0 on the current thread, then it does not count events Attributable to EL0 on the other thread, even if this thread is not executing at EL0.

Otherwise, for each Unattributable event, it is IMPLEMENTATION DEFINED whether the filtering applies.

In AArch32 state, the filtering controls are provided by the `PMEVTYPER<n>` and `PMCCFILTR` registers.

For more information, see the individual register descriptions.

### Reserved combinations of the filtering controls

The filtering controls are provided by the {P, U, NSK, NSU, NSH, M} fields of the controlling register, `PMEVTYPER<n>_EL0`, `PMCCFILTR_EL0`, `PMEVTYPER<n>`, or `PMCCFILTR`.

Some combinations of these fields select filtering options that do not represent a meaningful use case, and therefore these cases are reserved. [Table D5-2](#) shows these reserved filtering encodings.

**Table D5-2 Reserved filter encodings**

P	U	NSK	NSU	NSH	M	Exception level and state the filter applies to
0	1	1	1	x	x	Secure EL1 and Non-secure EL0 <sup>a</sup>
1	0	0	0	Not 0b00		EL0 and at least one of EL2 and EL3
1	0	0	1	Not 0b00		Secure EL0 and at least one of EL2 and EL3
1	0	1	1	x	x	Non-secure EL1 and Secure EL0 <sup>a</sup>
1	1	0	0	0	0	None
1	1	0	1	Not 0b00		Non-secure EL0 and at least one of EL2 and EL3

a. Software must not program the counter to count at EL0 in one state and at EL1 in the other state.

The reserved filtering encodings shown in [Table D5-2 on page D5-2147](#) are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. Implementations must implement the filtering controls as described in the appropriate register descriptions.

## D5.6.2 Accuracy of event filtering

The PMU architecture does not require event filtering to be accurate.

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- [Exception-related events](#).
- [Software increment events](#).

### Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level in which the event occurred. These events are:

- [EXC\\_TAKEN on page D5-2159](#), Exception taken.
- [EXC\\_RETURN on page D5-2160](#), Instruction architecturally executed, Condition code check pass, exception return.
- [CID\\_WRITE\\_RETIRED on page D5-2160](#), Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR.
- [TTBR\\_WRITE\\_RETIRED on page D5-2162](#), Instruction architecturally executed, Condition code check pass, write to translation table base.

The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to [CONTEXTIDR](#) after the return from the exception.

### Software increment events

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any speculatively executed software increment.

Software increment events must also be counted without the need for explicit synchronization. For example, two software increments executed without an intervening [Context synchronization event](#) must increment the event counter twice.

For more information, see [SW\\_INCR on page D5-2159](#), Instruction architecturally executed, Condition code check pass, software increment.

### Pseudocode description of event filtering

See [AArch64.CountEvents\(\)](#) and [AArch32.CountEvents\(\)](#) in [Chapter J1 ARMv8 Pseudocode](#) for a pseudocode description of event filtering. However, this function does not completely describe the behavior for Unattributable events.

## D5.7 Performance Monitors and Debug state

Events that count cycles are not counted in Debug state.

Events Attributable to the operations issued by the debugger through the external debug interface are not counted in Debug state.

In an implementation that supports multithreading, when the value of `PMEVTYPER<n>_EL0.MT` is 1, if an event is Attributable to an operation issued by the debugger through the external debug interface to another thread that is in Debug state, then the event is not counted, and it is IMPLEMENTATION DEFINED whether the event is counted when the counting thread is in Debug state.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when the counting PE is in Debug state. If the event might be counted, then the rules in [Filtering by Exception level and PE state on page D5-2147](#) apply for the current Security state in Debug state.

## D5.8 Counter enables

Table D5-3 shows an implementation that does not include EL2, and where the **PMCR.E** bit is a global counter enable bit, and **PMCNTENSET** provides an enable bit for each counter.

**Table D5-3 Event counter enables when an implementation does not include EL2**

<b>PMCR.E</b>	<b>PMCNTENSET[x] == 0</b>	<b>PMCNTENSET[x] == 1</b>
0	PMNx disabled	PMNx disabled
1	PMNx disabled	PMNx enabled

If the implementation includes EL2, then in addition to the **PMCR.E** and **PMCNTENSET** enable bits:

- **HDCR.HPME** overrides the value of **PMCR.E** for counters configured for access in Hyp mode.
- **HDCR.HPMN** specifies the number of performance counters that the Guest OS can access. The minimum permitted value of **HDCR.HPMN** is 1, meaning there must be at least one counter that the Guest OS can access.

Table D5-4 shows the combined effect of all the counter enable controls.

**Table D5-4 Event counter enables when an implementation includes EL2**

<b>HDCR.HPME</b>	<b>PMCR.E</b>	<b>PMCNTENSET[x] == 0</b>	<b>PMCNTENSET[x] == 1</b>	
			<b>x &lt; HDCR.HPMN</b>	<b>x ≥ HDCR.HPMN</b>
0	0	PMNx disabled	PMNx disabled	PMNx disabled
0	1	PMNx disabled	PMNx enabled	PMNx disabled
1	0	PMNx disabled	PMNx disabled	PMNx enabled
1	1	PMNx disabled	PMNx enabled	PMNx enabled

### Note

The effect of **HDCR**.{HPME, HPMN} on the counter enables applies in both Security states. However, in Secure state the value returned for **PMCR.N** is not affected by **HDCR.HPMN**.

EL2 does not affect the enabling of **PMCCNTR**. Table D5-5 shows the **PMCCNTR** enables, for all implementations.

**Table D5-5 Cycle counter enables**

<b>PMCR.E</b>	<b>PMCNTENSET[31] == 0</b>	<b>PMCNTENSET[31] == 1</b>
0	<b>PMCCNTR</b> disabled	<b>PMCCNTR</b> disabled
1	<b>PMCCNTR</b> disabled	<b>PMCCNTR</b> enabled

## D5.9 Counter access

All implemented counters are accessible in EL3, Secure EL1 and EL2. If EL2 is implemented the hypervisor uses [HDCR.HPMN](#) to reserve an event counter, with the effect that software cannot access that counter and its associated state from Non-secure EL1 or from Non-secure EL0.

### ———— Note ————

This section describes a counter as being accessible from a particular Exception level and state. However, access to the registers is subject to the access permissions described in [Access permissions on page D5-2176](#). In particular, accesses from EL0 might be UNDEFINED and accesses might be trapped to EL1 or EL2.

### D5.9.1 PMNx event counters

For an implementation that includes EL2 and EL3, [Table D5-6](#) shows how the values of the [HDCR.HPMN](#) field control the behavior of accesses to the PMNx event counter registers.

**Table D5-6 Result of PMNx event counter accesses**

Condition	Secure state			Non-secure state		
	EL3	EL1	EL0	EL2	EL1	EL0
$x < \text{HDCR.HPMN}$	Succeeds	Succeeds	Succeeds	Succeeds	Succeeds	Succeeds
$x \geq \text{HDCR.HPMN}$	Succeeds	Succeeds	Succeeds	Succeeds	No access	No access

Where [Table D5-6](#) shows no access:

- If [PMSELR.SEL](#) is  $x$  then:
  - A direct read of [PMXEVTYPER](#) or [PMXEVCNTR](#) is CONSTRAINED UNPREDICTABLE.
  - A direct write to [PMXEVTYPER](#) or [PMXEVCNTR](#) is CONSTRAINED UNPREDICTABLE.
- A direct read of [PMEVTYPER<n>](#) or [PMEVCNTR<n>](#) is CONSTRAINED UNPREDICTABLE.
- A direct write of [PMEVTYPER<n>](#) or [PMEVCNTR<n>](#) is CONSTRAINED UNPREDICTABLE.
- For direct reads and direct writes, [PMOVSLR\[x\]](#), [PMOVSSET\[x\]](#), [PMCINTENSET\[x\]](#), [PMCINTENCLR\[x\]](#), [PMINTENSET\[x\]](#), and [PMINTENCLR\[x\]](#) are RAZ/WI.
- Direct writes to [PMSWINC\[x\]](#) are ignored.
- A direct write of 1 to [PMCR.P](#) does not reset PMNx.

For more information on the CONSTRAINED UNPREDICTABLE behavior of the Performance Monitor Extension, see:

- For AArch32, [The Performance Monitors Extension on page K1-6103](#).
- For AArch64, [The Performance Monitors Extension on page K1-6121](#).

### ———— Note ————

In Secure state, and in the Non-secure EL2 mode, the value of [HDCR.HPMN](#) does not affect the value returned for [PMCR.N](#).

### D5.9.2 Cycle counter

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. The only control over the cycle counter is an access permission control for EL0. See [Access permissions on page D5-2176](#).

## D5.10 Events, event numbers, and mnemonics

The following sections describe the events that can be counted and their associated event numbers, and the mnemonics for the events:

- [Definitions](#).
- [The event number space on page D5-2156](#).
- [Common event numbers on page D5-2156](#).
- [Common architectural event numbers on page D5-2159](#).
- [Common microarchitectural event numbers on page D5-2163](#).
- [Meaningful ratios between common microarchitectural events on page D5-2174](#).
- [Required events on page D5-2174](#).
- [IMPLEMENTATION DEFINED event numbers on page D5-2175](#).

### D5.10.1 Definitions

The following subsections give more information about terms used in the event definitions:

- [Definition of terms](#).
- [Levels of caches and TLBs on page D5-2155](#).
- [Shared caches and buses on page D5-2155](#).

#### Definition of terms

##### Speculatively executed

Many events relate to speculatively executed operations. Here, speculatively executed means the PE did some work associated with one or more instructions but the instructions were not necessarily architecturally executed.

An instruction might create one or more *microarchitectural operations* ( $\mu$ -ops) at any point in the execution pipeline. For the purpose of event counting, the  $\mu$ -ops are counted. The definition of a  $\mu$ -op is implementation specific. An architecture instruction might create more than one  $\mu$ -op for each instruction.  $\mu$ -ops might also be removed or merged in the execution stream, so an architecture instruction might create no  $\mu$ -ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of  $\mu$ -ops is permitted.

This means there is no architecturally guaranteed relationship between a speculatively executed  $\mu$ -op and an architecturally executed instruction. The results of such an operation can also be discarded, if it transpires that the operation was not required, such as a mispredicted branch. Therefore, ARMv8-A defines these events as *operation speculatively executed*, where appropriate.

##### ———— Note ————

The definition of *speculatively executed* does not mean only those operations that are executed speculatively and later abandoned, for example due to a branch misprediction or fault. That is, speculatively executed operations must count operations on both false and correct execution paths.

The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

For example, an implementation might split an A32 or T32 LDM instruction of six registers into six  $\mu$ -ops, one for each load, and a seventh address-generation operation to determine the base address or writeback address. Also, for doubleword alignment, the six load  $\mu$ -ops might combine into four operations, that is, a word load, two doubleword loads, and a second word load. This single instruction can then be counted as five, or possibly six, events:

- Four (Operation speculatively executed - Load) events.
- One (Operation speculatively executed - Integer data processing) event.
- One (Operation speculatively executed - Software change of the PC) event if the PC was one of the six registers in the LDM instruction.

Different groups of events can have different IMPLEMENTATION DEFINED definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example is of the base type, operation speculatively executed.

For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Within these groups, events are commonly defined with reference to a particular architecture instruction or group of instructions. In the case of speculatively executed operations this means operations with semantics that map to that type of instruction.

### Instruction memory access

A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:

- Fetching instructions that are architecturally executed.
- The result of the execution of an instruction preload instruction, PLI.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is IMPLEMENTATION DEFINED. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

### Memory-read operations

A PE accesses memory through memory-read and memory-write operations. A memory-read operation might be due to:

- The result of an architecturally executed memory-reading instructions.
- The result of a speculatively executed memory-reading instructions.
- A translation table walk.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to:

- Memory-read operations or memory-write operations that miss in the cache
- The execution of a data preload instruction.
- The execution of an instruction preload instruction on a unified cache.
- The execution of a cache maintenance instruction.

#### **Note**

A preload instruction or cache maintenance instruction is not, in itself, an access to that cache. However, it might generate cache refills which are then treated as memory-read operations beyond that cache.

- Speculation that a future instruction might access the memory location.

This list is not exhaustive.

The relationship between memory-read instructions and memory-read operations is IMPLEMENTATION DEFINED. For example, for some implementations an LDP instruction that reads two 64-bit registers might generate one memory-read operation if the address is quadword-aligned, but for other addresses it generates two or more memory-read operations.

### Memory-write operations

Memory-write operations might be due to:

- The result of an architecturally executed memory-writing instructions.
- The result of a speculatively executed memory-writing instructions.

---

#### Note

---

Speculatively executed memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a memory-write operation that is later undone in some implementation specific way.

---

For levels of cache hierarchy beyond the Level 1 caches, memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see memory-read operations.
- The execution of a cache maintenance instruction.

---

#### Note

---

A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as memory-write operations beyond that cache.

---

- The result of a coherency request from another PE.

This list is not exhaustive.

The relationship between memory-writing instructions and memory-write operations is IMPLEMENTATION DEFINED. For example, for some implementations an STP instruction that writes two 64-bit registers might generate one memory-write operation if the address is quadword-aligned, but for other addresses it generates two or more memory-write operations. In some implementations, the result of two STR instructions that write to adjacent memory might be merged into a single memory-write operation.

---

#### Note

---

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

---

### Instruction architecturally executed

*Instruction architecturally executed* is a class of event that counts for each instruction of the specified type. Architecturally executed means that the program flow is such that the counted instruction would be executed in a *Simple sequential execution* of the program. Therefore an instruction that has been executed and retired is defined to be *architecturally executed*. When a PE can perform speculative execution, an instruction is not architecturally executed if the PE discards the results of the speculative execution.

If an instruction that would be executed in a *Simple sequential execution* of the program generates a synchronous exception, it is IMPLEMENTATION DEFINED whether the instruction is counted.

Each architecturally executed instruction is counted once, even if the implementation splits the instruction into multiple operations. Instructions that have no visible effect on the architectural state of the PE are architecturally executed if they form part of the architecturally executed program flow. The point where such instructions are retired is IMPLEMENTATION DEFINED.

Examples of instructions that have no visible effect are:

- A NOP.
- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.

The point at which an event causes an event counter to be updated is not defined.

Unless otherwise stated, all instructions of the specified type are counted even if they have no visible effect on the architectural state of the PE. This includes a conditional instruction that fails its Condition code check.

For events that count only the execution of instructions that update context state, such as writes to the [CONTEXTIDR](#), if such an instruction is executed twice without an intervening [Context synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the first instruction is counted.

#### Instruction architecturally executed, Condition code check pass

*Instruction architecturally executed, Condition code check pass* is a class of events that explicitly do not occur for:

- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.
- A Test and Branch on Zero, TBZ, instruction that does not branch.
- A Test and Branch on Nonzero, TBNZ, instruction that does not branch.
- A Store-Exclusive instruction that does not write to memory.

Otherwise, the definition of architecturally executed is the same as for *Instruction architecturally executed*.

#### Levels of caches and TLBs

The mapping of different levels of cache or TLB to the PMU events is determined by the implementation. Although the [CLIDR\\_EL1](#), or the AArch32 [CLIDR](#), defines the implemented levels of cache, the architecture does provide any way of determining implemented levels of TLB. Also, many implementations include structures that provide some caching at a higher level than the level 1 caches or TLBs. Typically, these structures, that might be called Level 0 caches, or mini caches, or microcaches, are invisible to software. The implementation-specific nature of cache and TLB implementations mean that, in general, PMU event counts cannot be used reliably to make direct comparisons between different implementations.

#### Shared caches and buses

There is no architectural concept of a *shared* component. However, when a cache, a bus, or any other system component that might generate countable events is implemented, and:

- The extent of the first-order effects due to an event from that component are only applicable to a single PE, then the event is not shared.
- Otherwise, the event is shared.

Second-order effects are not considered when determining if an event is shared.

#### Example D5-3 First and second order effects of a cache miss in a multiple-PE implementation

In an implementation that consists of two PEs, each with its own L1 cache, a cache miss by one of the PEs is a first-order effect of an access to its cache. Any snoop that is performed on the L1 cache of the other PE in the implementation as a result of that cache miss is a second order effect.

---

#### Note

Shared events are inherently linked to microarchitectures and so the implementer must make an informed decision about how such events are implemented.

---

## D5.10.2 The event number space

In ARMv8.0, the event number space is 12 bits. ARMv8.1 extends the event number space to 16 bits, and is allocated as follows:

0x0000–0x003F **and** 0x4000–0x403F

Common architectural and microarchitectural events, discoverable using PMCEID<n>\_EL0.

ARM defines these event numbers. Supported events in this range can be discovered using:

- The [PMCEID0\\_EL0](#) and [PMCEID1\\_EL0](#) registers in AArch64 state.
- The [PMCEID0](#) and [PMCEID1](#) registers in AArch32 state.

For more information see:

- [Common event numbers](#).
- [Common architectural event numbers on page D5-2159](#).
- [Common microarchitectural event numbers on page D5-2163](#).

0x0040–0x00BF **and** 0x4040–0x40BF

ARM recommended common architectural and microarchitectural events.

These events are IMPLEMENTATION DEFINED. For more information see:

- [IMPLEMENTATION DEFINED event numbers on page D5-2175](#).
- [Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events](#).

0x8000–0x80BF **and** 0xC000–0xC0BF

Reserved.

### All other values

IMPLEMENTATION DEFINED events.

For more information see [IMPLEMENTATION DEFINED event numbers on page D5-2175](#).

To address this extended number space, the [PMEVTYPER<n>\\_EL0.evtCount](#) is extended to 16 bits.

## D5.10.3 Common event numbers

The event numbers of the common events are reserved for the specified events. Each of these event numbers must either:

- Be used for its assigned event.
- Not be used.

However, see [Required events on page D5-2174](#).

When an implementation supports monitoring of an event that is assigned a common event number, ARM strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from the IMPLEMENTATION DEFINED range.

### ————— **Note** —————

ARM might define other common event numbers. This is one reason why software must not assume that an event with an assigned common event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

Table D5-7 lists the PMU architectural and microarchitectural event numbers in event number order. The entries in the *Event mnemonic* column link to the event description in *Common architectural event numbers on page D5-2159* or *Common microarchitectural event numbers on page D5-2163*.

**Table D5-7 PMU event numbers**

Event number	Event type	Event mnemonic	Description
0x0000	Architectural	<a href="#">SW_INCR</a>	Instruction architecturally executed, Condition code check pass, software increment
0x0001	Microarchitectural	<a href="#">L1I_CACHE_REFILL</a> <sup>a</sup>	Attributable Level 1 instruction cache refill
0x0002	Microarchitectural	<a href="#">L1I_TLB_REFILL</a> <sup>a</sup>	Attributable Level 1 instruction TLB refill
0x0003	Microarchitectural	<a href="#">L1D_CACHE_REFILL</a> <sup>a</sup>	Attributable Level 1 data cache refill
0x0004	Microarchitectural	<a href="#">L1D_CACHE</a>	Attributable Level 1 data cache access
0x0005	Microarchitectural	<a href="#">L1D_TLB_REFILL</a> <sup>a</sup>	Attributable Level 1 data TLB refill
0x0006	Architectural	<a href="#">LD_RETIRED</a>	Instruction architecturally executed, Condition code check pass, load
0x0007	Architectural	<a href="#">ST_RETIRED</a>	Instruction architecturally executed, Condition code check pass, store
0x0008	Architectural	<a href="#">INST_RETIRED</a>	Instruction architecturally executed
0x0009	Architectural	<a href="#">EXC_TAKEN</a>	Exception taken
0x000A	Architectural	<a href="#">EXC_RETURN</a>	Instruction architecturally executed, Condition code check pass, exception return
0x000B	Architectural	<a href="#">CID_WRITE_RETIRED</a>	Instruction architecturally executed, Condition code check pass, write to <a href="#">CONTEXTIDR</a>
0x000C	Architectural	<a href="#">PC_WRITE_RETIRED</a>	Instruction architecturally executed, Condition code check pass, software change of the PC
0x000D	Architectural	<a href="#">BR_IMMED_RETIRED</a>	Instruction architecturally executed, immediate branch
0x000E	Architectural	<a href="#">BR_RETURN_RETIRED</a>	Instruction architecturally executed, Condition code check pass, procedure return
0x000F	Architectural	<a href="#">UNALIGNED_LDST_RETIRED</a>	Instruction architecturally executed, Condition code check pass, unaligned load or store
0x0010	Microarchitectural	<a href="#">BR_MIS_PRED</a>	Mispredicted or not predicted branch speculatively executed
0x0011	Microarchitectural	<a href="#">CPU_CYCLES</a>	Cycle
0x0012	Microarchitectural	<a href="#">BR_PRED</a>	Predictable branch speculatively executed
0x0013	Microarchitectural	<a href="#">MEM_ACCESS</a>	Data memory access
0x0014	Microarchitectural	<a href="#">L1I_CACHE</a>	Attributable Level 1 instruction cache access
0x0015	Microarchitectural	<a href="#">L1D_CACHE_WB</a>	Attributable Level 1 data cache write-back
0x0016	Microarchitectural	<a href="#">L2D_CACHE</a>	Attributable Level 2 data cache access
0x0017	Microarchitectural	<a href="#">L2D_CACHE_REFILL</a> <sup>a</sup>	Attributable Level 2 data cache refill

Table D5-7 PMU event numbers (continued)

Event number	Event type	Event mnemonic	Description
0x0018	Microarchitectural	L2D_CACHE_WB	Attributable Level 2 data cache write-back
0x0019	Microarchitectural	BUS_ACCESS	Bus access
0x001A	Microarchitectural	MEMORY_ERROR	Local memory error
0x001B	Microarchitectural	INST_SPEC	Operation speculatively executed
0x001C	Architectural	TTBR_WRITE_RETIRED	Instruction architecturally executed, Condition code check pass, write to <a href="#">TTBR</a>
0x001D	Microarchitectural	BUS_CYCLES	Bus cycle
0x001E	Architectural	CHAIN	For odd-numbered counters, increments the count by one for each overflow of the preceding even-numbered counter. For even-numbered counters, there is no increment.
0x001F	Microarchitectural	L1D_CACHE_ALLOCATE	Attributable Level 1 data cache allocation without refill
0x0020	Microarchitectural	L2D_CACHE_ALLOCATE	Attributable Level 2 data cache allocation without refill
0x0021	Architectural	BR_RETIRED	Instruction architecturally executed, branch
0x0022	Microarchitectural	BR_MIS_PRED_RETIRED	Instruction architecturally executed, mispredicted branch
0x0023	Microarchitectural	STALL_FRONTEND	No operation issued due to the frontend
0x0024	Microarchitectural	STALL_BACKEND	No operation issued due to backend
0x0025	Microarchitectural	L1D_TLB	Attributable Level 1 data or unified TLB access
0x0026	Microarchitectural	L1I_TLB	Attributable Level 1 instruction TLB access
0x0027	Microarchitectural	L2I_CACHE	Attributable Level 2 instruction cache access
0x0028	Microarchitectural	L2I_CACHE_REFILL <sup>a</sup>	Attributable Level 2 instruction cache refill
0x0029	Microarchitectural	L3D_CACHE_ALLOCATE	Attributable Level 3 data or unified cache allocation without refill
0x002A	Microarchitectural	L3D_CACHE_REFILL <sup>a</sup>	Attributable Level 3 data or unified cache refill
0x002B	Microarchitectural	L3D_CACHE	Attributable Level 3 data or unified cache access
0x002C	Microarchitectural	L3D_CACHE_WB	Attributable Level 3 data or unified cache write-back
0x002D	Microarchitectural	L2D_TLB_REFILL <sup>a</sup>	Attributable Level 2 data or unified TLB refill
0x002E	Microarchitectural	L2I_TLB_REFILL <sup>a</sup>	Attributable Level 2 instruction TLB refill
0x002F	Microarchitectural	L2D_TLB	Attributable Level 2 data or unified TLB access
0x0030	Microarchitectural	L2I_TLB	Attributable Level 2 instruction TLB access

a. For more information, see *Meaningful ratios between common microarchitectural events* on page D5-2174.

The `PMCEID0_EL0` and `PMCEID1_EL0` registers identify the events that an implementation supports.

Future revisions of this manual, or of the architecture, might define additional common event numbers. Events that do not require additional features in the PMU can be implemented retrospectively, meaning such events can be supported as part of a PMUv3 implementation.

---

**Note**

This means that an ARMv7 PMUv2 implementation can include support for any of the event numbers defined in [Table D5-7 on page D5-2157](#).

---

#### D5.10.4 Common architectural event numbers

This section describes the defined common architectural event numbers.

For the common features, normally the counters must increment only once for each event. The event descriptions include any exceptions to this rule.

In these definitions, the term *architecturally executed* means that the instruction flow is such that the counted instruction would have been executed in a *Simple sequential execution* model.

The common architectural event numbers are:

**0x0000, SW\_INCR, Instruction architecturally executed, Condition code check pass, software increment**

The counter increments on writes to the [PMSWINC](#) register.

If the PE performs two architecturally executed writes to the [PMSWINC](#) register without an intervening *Context synchronization event*, then the counter is incremented twice.

If [PMEVTYPEPER<n>\\_EL0](#).evtCount is set to 0x000, then in AArch64 state, counts MSR writes to [PMSWINC\\_EL0](#) with bit [n] set to 1.

If the value of [PMEVTYPEPER<n>\\_EL0](#).MT is 1 then, in a multithreaded implementation, this counts writes by all PEs that have the same affinity at level 1 and above.

**0x0006, LD\_RETIRED, Instruction architecturally executed, Condition code check pass, load**

The counter increments for every executed memory-reading instruction.

---

**Note**

This event 0x0006 does not count the return status value of a Store-Exclusive instruction.

---

Whether the preload instructions PRFM, PLD, PLDW, PLI, count as memory-reading instructions is IMPLEMENTATION DEFINED. ARM recommends that if the instruction is not implemented as a NOP then it is counted as a memory-reading instruction.

**0x0007, ST\_RETIRED, Instruction architecturally executed, Condition code check pass, store**

The counter increments for every executed memory-writing instruction.

DC ZVA is counted as a store.

The counter does not increment for a Store-Exclusive instruction that fails.

**0x0008, INST\_RETIRED, Instruction architecturally executed**

The counter increments for every architecturally executed instruction.

**0x0009, EXC\_TAKEN, Exception taken**

The counter increments for each exception taken. See [Exception-related events on page D5-2148](#).

---

**Note**

The counter counts the PE exceptions described in:

- For exceptions taken to an Exception level using AArch64, [Exception entry on page D1-1799](#).
  - For exceptions taken to an Exception level using AArch32, [AArch32 state exception descriptions on page G1-4376](#).
-

**0x000A, EXC\_RETURN, Instruction architecturally executed, Condition code check pass, exception return**

The counter increments for each executed exception return instruction. See also [Exception-related events on page D5-2148](#). The following sections define the counted instructions:

- For an exception return from an Exception level using AArch64, [Exception return on page D1-1815](#).
- For an exception return from an Exception level using AArch32, [Exception return instructions on page G1-4360](#).

**0x000B, CID\_WRITE\_RETIRED, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR**

The counter increments for every write to `CONTEXTIDR`. See [Exception-related events on page D5-2148](#).

If the PE performs two architecturally-executed writes to `CONTEXTIDR` without an intervening [Context synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the first write is counted.

When ARMv8.1-VHE is implemented, the counter is:

- Incremented as a result of the retirement of an instruction accessing the named register `CONTEXTIDR_EL1`, even when executing at EL2.
- Not incremented as a result of the retirement of an instruction accessing the named `CONTEXTIDR_EL12`.

———— **Note** ————

The event is defined by the name used to access the register. The counter does not count writes to the named register `CONTEXTIDR_EL2`.

**0x000C, PC\_WRITE\_RETIRED, Instruction architecturally executed, Condition code check pass, software change of the PC**

The counter increments for every software change of the PC. This includes all:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions, ERET and RET.

It is IMPLEMENTATION DEFINED whether the counter increments for any or all of:

- BRK and BKPT instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, SVC, HVC, and SMC.

It is IMPLEMENTATION DEFINED whether an ISB is counted as a software change of the PC.

The counter does not increment for exceptions other than those explicitly identified in these lists.

———— **Note** ————

Conditional branches are only counted if the branch is taken.

**0x000D, BR\_IMMED\_RETIRED, Instruction architecturally executed, immediate branch**

The counter counts all immediate branch instructions that are architecturally executed.

In AArch32 state, the counter increments each time the PE executes one of the following instructions:

- B{<c>} <label>.
- BL{<c>} <label>.
- BLX{<c>} <label>.
- CBZ <Rn>, <label>.
- CBNZ <label>.

In AArch64 state, the counter increments each time the PE executes an immediate branch instructions:

- B <label>.
- B.cond <label>.
- BL <label>.
- CBZ <Rn>, <label>.
- CBNZ <Rn>, <label>.
- TBZ <Rn>, <label>.
- TBNZ <Rn>, <label>.

**Note**

Conditional branches are always counted, regardless of whether the branch is taken.

If an ISB is counted as a software change of the PC instruction, then it is IMPLEMENTATION DEFINED whether an ISB is counted as an immediate branch instruction.

**0x000E, BR\_RETURN\_RETIRED, Instruction architecturally executed, Condition code check pass, procedure return**

In AArch32 state, the counter counts the following procedure return instructions:

- BX R14.
- MOV PC, LR.
- POP {..., PC}.
- LDR PC, [SP], #offset.

**Note**

The counter counts only the listed instructions as procedure returns. For example, it does not count the following as procedure return instructions:

- BX R0, because Rm != R14.
- MOV PC, R0, because Rm != R14.
- LDM SP, {..., PC}, because writeback is not specified.
- LDR PC, [SP, #offset], because this specifies the wrong addressing mode.

In AArch64 state, the counter counts all architecturally executed RET instructions.

**0x000F, UNALIGNED\_LDST\_RETIRED, Instruction architecturally executed, Condition code check pass, unaligned load or store**

The counter counts each memory-reading instruction or memory-writing instruction access that would generate an Alignment fault when Alignment fault checking is enabled.

This event does not count accesses that would generate an SP alignment fault exception if the applicable stack pointer alignment check is enabled, unless that access would also generate an Alignment fault Data Abort exception if Alignment fault checking is enabled.

It is IMPLEMENTATION DEFINED whether this event counts accesses that generate an exception, including accesses that do generate Alignment fault Data Abort exceptions.

See [SP alignment checking on page D1-1793](#) for more information.

See [Unaligned data access](#) on page E2-2777 for more information.

#### 0x001C, TTBR\_WRITE\_RETIRED, Instruction architecturally executed, Condition code check pass, write to TTBR

The counter counts writes to [TTBR0\\_EL1](#) and [TTBR1\\_EL1](#) in AArch64 state and [TTBR0](#) and [TTBR1](#) in AArch32 state. When EL3 is implemented and using AArch32, this includes counting writes to both banked copies of [TTBR0](#) and [TTBR1](#). See [Exception-related events](#) on page D5-2148.

If the PE executes two writes to the same [TTBR](#), without an intervening [Context synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the first write to the [TTBR](#), is counted.

If EL3 is implemented and using AArch64, the counter does not count writes to [TTBR0\\_EL3](#).

If EL2 is implemented and using AArch64, the counter does not count writes to [TTBR0\\_EL2](#) and to [VTTBR\\_EL2](#).

If EL2 is implemented and using AArch32, the counter does not count writes to [HTTBR](#) and to [VTTBR](#).

When ARMv8.1-VHE is implemented, the counter is:

- Incremented as a result of the retirement of an instruction accessing the named registers [TTBR0\\_EL1](#) and [TTBR1\\_EL1](#).
- Not incremented as a result of the retirement of an instruction accessing the named registers [TTBR0\\_EL12](#) and [TTBR1\\_EL12](#).

#### 0x001E, CHAIN

For an odd-numbered counter, increments when an overflow occurs on the preceding even-numbered counter on the same PE. Even-numbered counters never increment as a result of this event. This means the CHAIN event links the odd-numbered counter with the preceding even-numbered counter to provide a 64-bit counter.

##### Note

- The CHAIN event means a system can provide  $N$  32-bit counters,  $N/2$  64-bit counters, or a mixture of 32-bit counters and 64-bit counters.
- The CHAIN event only counts overflows from the preceding even-numbered counter on the same PE. This means it is unaffected by the value of [PMEVTYPER<n>\\_EL0.MT](#).

There is no atomic access to a pair of counters, so if software reads a counter-pair that is enabled, it must use a high-low-high read sequence, or employ reasonable heuristics, to avoid tearing. Similarly, if using CHAIN events, when disabling the counters software must take care that the result is not torn by the low counter overflowing at the same time as the counters are disabled [Example D5-4](#) shows suitable sequences for disabling and enabling CHAIN counters.

#### Example D5-4 Usage examples for 64-bit counters

An example high-low-high read sequence for a 64-bit counter is:

```
MRS W2,PMEVCNTR1_EL0    ;; read high counter, must be odd-numbered
retry:
  ISB                    ;; force ordering
  MRS W0,PMEVCNTR0_EL0    ;; read low counter
                          ;; must return the previous counter to PMEVCNTR1_EL0
  ISB                    ;; force ordering
  MRS W1,PMEVCNTR1_EL0    ;; read high counter
  CMP W1,W2
  BNE retry              ;; if the high counter has changed, then retry
```

When disabling a pair of counters that are paired by a CHAIN event, software must:

1. Disable the low counter, by setting [PMCNTENCLR\\_EL0\[n\]](#) to 1.  
Typically, software uses a read-modify-write sequence to update [PMCNTENCLR\\_EL0](#).
2. Execute an ISB instruction, or perform another [Context synchronization event](#).

3. Disable the high counter, by setting `PMCNTENCLR_EL0[n+1]` to 1, or setting `PMCR_EL0.E` to 0.

When enabling a pair of counters that are paired by a CHAIN event, software must:

1. Enable the high counter, by setting `PMCNTENCLR_EL0[n+1]` to 0 and, if necessary, setting `PMCR_EL0.E` to 1.
2. Execute an ISB instruction, or perform another *Context synchronization event*.
3. Enable the low counter by setting `PMCNTENCLR_EL0[n]` to 0.

---

When using 64-bit counters, the architecture does not define the latency between the first counter overflowing and the second counter incrementing the CHAIN event. There is no requirement for updates to occur synchronously, but software reading or enabling the counter pair using a *low-ISB-high* sequence, as shown in [Example D5-4 on page D5-2162](#), must not observe the low counter incrementing and overflowing for the event and the high counter not incrementing for the resulting CHAIN event. This means that the ISB executed after reading the low counter must ensure the completion of the update of the high counter by the CHAIN event.

#### Note

The way the CHAIN event operates means that, to filter the Exception levels and Security states in which the event is counted, software must:

- Program `PMEVTYPER<n>_EL0` to count the event in the required conditions.
  - Program `PMEVTYPER<n+1>_EL0` to count the CHAIN event in all Exception levels and states.
- 

#### **0x0021, BR\_RETIRED, Instruction architecturally executed, branch.**

The counter counts all branches on the architecturally executed path that would incur cost if mispredicted.

- Counts all branch instructions, memory-reading and data-processing instructions that explicitly write to the PC, at retirement.
- Counts both taken and not-taken branches.
- It is IMPLEMENTATION DEFINED whether this includes each of:
  - Unconditional direct branch instructions.
  - Exception-generating instructions.
  - Exception return instructions.
  - Context synchronization instructions.

### **D5.10.5 Common microarchitectural event numbers**

This section describes the defined common microarchitectural event numbers.

The common microarchitectural events are features that are likely to be implemented across a wide range of implementations. Unlike the common architectural events, there can be some IMPLEMENTATION DEFINED variation between definitions on different implementations.

Unless otherwise stated, the common microarchitectural features relate only to events resulting from the operation of the PE counting the events. Events resulting from the operation of other PEs that might share a resource must not be counted. Where a resource can be subject to events that do not result from the operation of any of the PEs that share it, ARM recommends that the resource implements its own event counters. An example of a resource that might require its own event counters is a shared Level 2 cache that is subject to accesses from a system coherency port on that cache.

The event definitions relating to Level 2 caches generally assume the Level 2 cache is shared. The event definitions relating to Level 1 caches generally assume the Level 1 cache is not shared.

The common microarchitectural event numbers are:

**0x0001, L1I\_CACHE\_REFILL, Attributable Level 1 instruction cache refill**

The counter counts Attributable instruction memory accesses that cause a refill of at least the Level 1 instruction or unified cache. This includes each instruction memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count cache maintenance instructions.

See also:

- [Attributability on page D5-2144.](#)
- [Meaningful ratios between common microarchitectural events on page D5-2174.](#)

**0x0002, L1I\_TLB\_REFILL, Attributable Level 1 instruction TLB refill**

The counter counts Attributable instruction memory accesses that cause a TLB refill of at least the Level 1 instruction TLB. This includes each instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [Attributability on page D5-2144.](#)
- [Meaningful ratios between common microarchitectural events on page D5-2174.](#)

**0x0003, L1D\_CACHE\_REFILL, Attributable Level 1 data cache refill**

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a refill of at least the Level 1 data or unified cache from outside the Level 1 cache. Each access to a cache line that causes a new linefill is counted, including those from instructions that generate multiple accesses, such as load or store multiples, and PUSH and POP instructions. In particular, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by another Level 1 data or unified cache, or a Level 2 cache, or memory.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count:

- Accesses that do not cause a new Level 1 cache refill but are satisfied from refilling data of a previous miss.
- Accesses to a cache line that generate a memory access but not a new linefill, such as write-through writes that hit in the cache.
- Cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 cache, for example:
  - A write of a full cache line from a coalescing buffer.
  - A [DC ZVA](#) operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

See also:

- [Attributability on page D5-2144.](#)

- [Meaningful ratios between common microarchitectural events on page D5-2174.](#)

#### 0x0004, L1D\_CACHE, Attributable Level 1 data cache access

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a cache access to at least the Level 1 data or unified cache. Each access to a cache line is counted including the multiple accesses of instructions, such as LDM or STM. Each access to other Level 1 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count cache maintenance instructions.

See also [Attributability on page D5-2144.](#)

#### 0x0005, L1D\_TLB\_REFILL, Attributable Level 1 data TLB refill

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a TLB refill of at least the Level 1 data or unified TLB. It counts each read or write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [Attributability on page D5-2144.](#)
- [Meaningful ratios between common microarchitectural events on page D5-2174.](#)

#### 0x0010, BR\_MIS\_PRED, Mispredicted or not predicted branch speculatively executed

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, ARM recommends that the counter counts all branches that are not taken.

#### 0x0011, CPU\_CYCLES, Cycle

The counter increments on every cycle.

All counters are subject to changes in clock frequency, including when a WFI or WFE instruction stops the clock. This means that it is CONSTRAINED UNPREDICTABLE whether or not CPU\_CYCLES continues to increment when the clocks are stopped by WFI and WFE instructions.

#### ————— Note —————

Unlike [PMCCNTR](#), this count is not affected by [PMCR.DP](#), [PMCR.D](#), or [PMCR.C](#):

- The counter is not incremented in prohibited regions, so is not affected by [PMCR.DP](#).
- The counter increments on every cycle, regardless of the setting of [PMCR.D](#).
- The counter is reset when event counters are reset by [PMCR.P](#), never by [PMCR.C](#).

In a multithreaded implementation, CPU\_CYCLES counts each cycle for the processor for which this PE thread was active and could issue an instruction. For more information, see [Cycle event counting on multithreaded implementations on page D5-2173.](#)

#### 0x0012, BR\_PRED, Predictable branch speculatively executed

The counter counts every branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.

If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is IMPLEMENTATION DEFINED whether other branches are counted as predictable branches. ARM recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by [BR\\_MIS\\_PRED](#).

If no program-flow prediction resources are implemented, this event is optional, but ARM recommends that BR\_PRED counts all branches.

#### 0x0013, MEM\_ACCESS, Data memory access

The counter counts memory-read or memory-write operations that the PE made. The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The counter does not increment as a result of:

- Instruction memory accesses, see [Definition of terms on page D5-2152](#).
- Translation table walks.
- Cache maintenance instructions.
- Write-back from any cache.
- Refilling of any cache.

#### 0x0014, L1I\_CACHE, Attributable Level 1 instruction cache access

The counter counts Attributable instruction memory accesses that access at least the Level 1 instruction or unified cache. Each access to other Level 1 instruction memory structures, such as refill buffers, is also counted.

See also [Attributability on page D5-2144](#).

#### 0x0015, L1D\_CACHE\_WB, Attributable Level 1 data cache write-back

The counter counts every write-back of data from the Level 1 data or unified cache. The counter counts each write-back that causes data to be written from the Level 1 cache to outside of the Level 1 cache. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level 2 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 1 cache.
- Transfer of data from the Level 1 cache to outside of this cache made as a result of a coherency request. The conditions determining which of these are counted for transfers to other Level 1 caches within the same multiprocessor cluster are IMPLEMENTATION DEFINED.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

Whether write-backs made as a result of cache maintenance instructions is IMPLEMENTATION DEFINED.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 2 cache or memory.
- Writes from the PE that write through the Level 1 cache to outside of the Level 1 cache.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. See [Attributability on page D5-2144](#).

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [Attributability on page D5-2144](#).

**0x0016, L2D\_CACHE, Attributable Level 2 data cache access**

The counter counts Attributable memory-read or Attributable memory-write operations, that the PE made, that access at least the Level 2 data or unified cache. Each access to a cache line is counted including refills of and write-backs from the Level 1 data, instruction, or unified caches. Each access to other Level 2 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count:

- Operations made by other PEs that share this cache.
- Cache maintenance instructions.

See also [Attributability on page D5-2144](#).

**0x0017, L2D\_CACHE\_REFILL, Attributable Level 2 data cache refill**

The counter counts Attributable memory-read or Attributable memory-write operations, that the PE made, that access at least the Level 2 data or unified cache and cause a refill of a Level 1 data, instruction, or unified cache or of the Level 2 data or unified cache. Each read from or write to the cache that causes a refill from outside the Level 1 and Level 2 caches is counted.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 cache that cause a refill that is satisfied by another Level 2 cache, a Level 3 cache, or memory.
- Refills of and write-backs from any Level 1 data, instruction or unified cache that cause a refill from outside the Level 1 and Level 2 caches.
- Accesses to the Level 2 cache that cause a refill of a Level 1 cache from outside of the Level 1 and Level 2 caches, even if there is no refill of the Level 2 cache.

The counter does not count, as events on this PE:

- Accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.
- Accesses to the Level 2 cache that generate a memory access but not a new linefill, such as write-through writes that hit in the Level 2 cache.
- Accesses to the Level 2 cache that are part of a Level 1 cache refill or write-back that hit in the Level 2 cache so do not cause a refill from outside of the Level 1 and Level 2 caches.
- Operations made by other PEs that share this cache.
- Cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 and Level 2 caches, for example:
  - A write-back from a Level 1 cache to a Level 2 cache.
  - A write from a coalescing buffer of a full cache line.
  - A DC ZVA operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

See also:

- [Attributability on page D5-2144](#).
- [Meaningful ratios between common microarchitectural events on page D5-2174](#).

**0x0018, L2D\_CACHE\_WB, Attributable Level 2 data cache write-back**

The counter counts every write-back of data from the Level 2 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 2 cache to outside the Level 1 and Level 2 caches. For example, the counter counts:

- A write-back that causes data to be written to a Level 3 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 2 cache.

Each write-back is counted once, even if it requires multiple accesses to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 2 cache to outside the Level 1 and Level 2 cache made as a result of a coherency request.
- Write-backs made as a result of Cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 3 cache or memory.
- Writes from the PE or Level 1 data or unified cache that write through the Level 2 cache to outside the Level 1 and Level 2 caches.
- Transfers of data from the Level 2 cache to a Level 1 cache, to satisfy a Level 1 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [Attributability on page D5-2144](#).

#### 0x0019, **BUS\_ACCESS, Attributable Bus access**

The counter counts memory-read or memory-write operations that access outside of the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

The definition of a bus access is IMPLEMENTATION DEFINED but physically is a single beat rather than a burst. That is, for each bus cycle for which the bus is active.

Bus accesses include refills of and write-backs from data, instruction, and unified caches. Whether bus accesses include operations that do use the bus but not explicitly transfer data is IMPLEMENTATION DEFINED.

An Unattributable bus access occurs when a requestor outside the PE makes a request that results in a bus access, for example, a coherency request. If the bus is shared, then an Unattributable bus access is not counted. If the bus is not shared, then the event is counted.

If the bus is shared, then only Attributable bus accesses are counted. If the bus is not shared, then all bus accesses are counted.

Where an implementation has multiple buses at this boundary, this event counts the sum of accesses across all buses.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

See also:

- [Attributability on page D5-2144](#).
- [Meaningful ratios between common microarchitectural events on page D5-2174](#).

#### 0x001A, **MEMORY\_ERROR, Local memory error**

The counter counts every occurrence of a memory error signaled by a memory closely coupled to this PE. The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

**0x001B, INST\_SPEC, Operation speculatively executed**

The counter counts instructions that are speculatively executed by the PE. This includes instructions that are subsequently not architecturally executed. As a result, this event counts a larger number of instructions than the number of instructions architecturally executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

**0x001D, BUS\_CYCLES, Bus cycle**

The counter increments on every cycle of the interface at the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

———— **Note** —————

If the implementation clocks the external memory interface at the same rate as the processor hardware, the counter counts every cycle.

See also [Meaningful ratios between common microarchitectural events on page D5-2174](#).

**0x001F, L1D\_CACHE\_ALLOCATE, Attributable Level 1 data cache allocation without refill**

The counter increments on every Attributable write that writes an entire line into the Level 1 cache without fetching from outside the Level 1 cache, for example:

- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also [Attributability on page D5-2144](#).

**0x0020, L2D\_CACHE\_ALLOCATE, Attributable Level 2 data cache allocation without refill**

The counter increments on every Attributable write that writes an entire line into the Level 2 cache without fetching from outside the Level 1 or Level 2 caches, for example:

- A write-back from a Level 1 to Level 2 cache.
- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also [Attributability on page D5-2144](#).

**0x0022, BR\_MIS\_PRED\_RETIRED, Instruction architecturally executed, mispredicted branch**

The counter counts all instructions counted by BR\_RETIRED that were not correctly predicted. If no program-flow prediction resources are implemented, this event counts all retired not-taken branches.

**0x0023, STALL\_FRONTEND, No operation issued due to the frontend**

The counter counts every cycle counted by the CPU\_CYCLES event on which no operation was issued because there are no operations available to issue for this PE from the frontend.

The division between frontend and backend is IMPLEMENTATION DEFINED. Frontend and backend events must count at the same point in the pipeline.

———— **Note** —————

- For a simplified pipeline model of Fetch → Decode → Issue → Execute → Retire, ARM recommends that the events are counted when instructions are dispatched from Decode to Issue.
- On a given cycle, both events might be counted if the backend is unable to accept any operations and there are no operations available to issue from the frontend.

For more information, see [Cycle event counting on multithreaded implementations on page D5-2173](#).

**0x0024, STALL\_BACKEND, No operation issued due to the backend**

The counter counts every cycle counted by the [CPU\\_CYCLES](#) event on which no operation was issued because either:

- The backend is unable to accept any of the operations available for issue for this PE.
- The backend is unable to accept any operations.

For example, the back end might be unable to accept operations because of a resource conflict or non-availability.

The division between frontend and backend is IMPLEMENTATION DEFINED. Frontend and backend events must count at the same point in the pipeline. See [STALL\\_FRONTEND](#) for more information.

For more information, see [Cycle event counting on multithreaded implementations on page D5-2173](#).

**0x0025, L1D\_TLB, Attributable Level 1 data or unified TLB access**

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a TLB access to at least the Level 1 data or unified TLB. Each access to a TLB record is counted including the multiple accesses of instructions, such as LDM or STM.

The counter does not count TLB maintenance instructions.

See also [Attributability on page D5-2144](#).

**0x0026, L1I\_TLB, Attributable Level 1 instruction TLB access**

The counter counts each Attributable instruction memory access that causes a TLB access to at least the Level 1 instruction or unified TLB.

The counter does not count TLB maintenance instructions.

See also [Attributability on page D5-2144](#).

**0x0027, L2I\_CACHE, Attributable Level 2 instruction cache access**

The counter counts Attributable instruction memory accesses that access at least the Level 2 instruction or unified cache. Each Attributable access to other Level 2 instruction memory structures, such as refill buffers, is also counted.

See also [Attributability on page D5-2144](#).

**0x0028, L2I\_CACHE\_REFILL, Attributable Level 2 instruction cache refill**

The counter counts Attributable instruction memory accesses that cause a refill of at least the Level 2 instruction or unified cache. This includes each Attributable memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

A refill includes any Attributable access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count cache maintenance instructions.

See also:

- [Attributability on page D5-2144](#).
- [Meaningful ratios between common microarchitectural events on page D5-2174](#).

**0x0029, L3D\_CACHE\_ALLOCATE, Attributable Level 3 data cache allocation without refill**

The counter increments on every Attributable write that writes an entire line into the Level 3 cache without fetching from outside the Level 1, Level 2, or Level 3 cache, for example:

- A write-back from a Level 2 to Level 3 cache.
- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also [Attributability on page D5-2144](#).

#### 0x002A, L3D\_CACHE\_REFILL, Attributable Level 3 data cache refill

The counter counts each Attributable memory-read operation or Attributable memory-write operation that the PE makes that accesses at least the Level 3 data or unified cache and causes a refill of a Level 1 or Level 2 instruction, data, or unified cache or of the Level 3 data or unified cache. Each read from or write to the cache that causes a refill from outside the Level 1, Level 2, and Level 3 caches is counted.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count as events on this PE:

- Accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.
- Accesses to the Level 3 cache that generate a memory access but not a new linefill, such as write-through writes that hit in the Level 3 cache.
- Accesses to the Level 3 cache that are part of a Level 1 or Level 2 cache refill or write-back that hit in the Level 3 cache so do not cause a refill from outside of the Level 1, Level 2, and Level 3 caches.
- Operations made by other PEs that share this cache.
- Cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1, Level 2, and Level 3 cache, for example:
  - A write-back from a Level 2 to Level 3 cache.
  - A write of a full cache line from a coalescing buffer.
  - A [DC ZVA](#) operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

See also:

- [Attributability on page D5-2144.](#)
- [Meaningful ratios between common microarchitectural events on page D5-2174.](#)

#### 0x002B, L3D\_CACHE, Attributable Level 3 data cache access

The counter counts Attributable memory-read or Attributable memory-write operations, that the PE made, that access at least the Level 3 data or unified cache. Each access to a cache line is counted including refills of and write-backs from the Level 1 or Level 2 data, instruction, or unified caches. Each access to other Level 3 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count:

- Operations made by other PEs that share the Level 3 data or unified cache.
- Cache maintenance instructions.

See also [Attributability on page D5-2144.](#)

#### 0x002C, L3D\_CACHE\_WB, Attributable Level 3 data cache write-back

The counter counts every write-back of data from the Level 3 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 3 cache to outside of the Level 1, Level 2, and Level 3 caches. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level 4 cache, or to memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 3 cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 3 cache to outside the Level 1, Level 2, and Level 3 caches made as a result of a coherency request.

- A write-back made as a result of a Cache maintenance instruction.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 4 cache or memory.
- Writes from the PE, Level 1, or Level 2 data or unified cache, that write through the Level 3 cache to outside of the Level 3 cache.
- Transfers of data from the Level 3 cache to a Level 1 or Level 2 cache, to satisfy a Level 1 or Level 2 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then Unattributable write-back events are not counted. If the cache is not shared, then Unattributable write-back events are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [Attributability on page D5-2144](#).

#### 0x002D, L2D\_TLB\_REFILL, Attributable Level 2 data TLB refill

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a TLB refill of at least the Level 2 data or unified TLB. It counts each Attributable read or Attributable write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [Attributability on page D5-2144](#).
- [Meaningful ratios between common microarchitectural events on page D5-2174](#).

#### 0x002E, L2I\_TLB\_REFILL, Attributable Level 2 instruction TLB refill

The counter counts Attributable instruction memory accesses that cause a TLB refill of at least the Level 2 instruction TLB. This includes each Attributable instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [Attributability on page D5-2144](#).
- [Meaningful ratios between common microarchitectural events on page D5-2174](#).

#### 0x002F, L2D\_TLB, Attributable Level 2 data or unified TLB access

The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 data or unified TLB. Each access to a TLB record is counted, including the multiple accesses of instructions such as LDM or STM.

The counter does not count TLB maintenance instructions.

See also [Attributability on page D5-2144](#).

#### 0x0030, L2I\_TLB, Attributable Level 2 instruction TLB access

The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 instruction or unified TLB.

The counter does not count TLB maintenance instructions.

See also *Attributability* on page D5-2144.

### D5.10.6 Cycle event counting on multithreaded implementations

For most events, the event is only counted when it is attributable to the counting PE or thread, see *Attributability* on page D5-2144.

Multithreaded implementations can have various forms, some examples of these are:

- *Simultaneous Multithreading* (SMT), where every PE thread is active on every cycle.
- *Fine-grained Multithreading* (FGMT), also known as a Barrel processor, where one PE thread is active on each cycle, and this changes regularly.
- *Switch on Event Multithreading* (SoEMT), also known as *Coarse-grained Multithreading* (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

When the `PMEVTYPEPER<n>_EL0.MT` bit is set to 0, the `CPU_CYCLES` event only counts cycles on which the thread was active. For the example multithreaded implementations, this means that:

- For an SMT implementation, the `CPU_CYCLES` event counts every cycle.
- For a particular FGMT implementation, that alternates between two threads on each cycle, the `CPU_CYCLES` event counts every other cycle.
- For a particular SoEMT implementation, that is waiting for a long latency operation, the `CPU_CYCLES` event does not count cycles, as the PE thread is not active.

If the `PMEVTYPEPER<n>_EL0.MT` bit is set to 1, the processor counts each cycle, and can only count a maximum of one cycle each cycle.

In addition, the `STALL_FRONTEND` and `STALL_BACKEND` events only count cycles that are counted by the `CPU_CYCLES` event, and so have the same limitation. For example, in an SMT implementation, if a PE thread cannot issue an instruction because of contention with other PE threads, these are counted as `STALL_BACKEND` cycles.

If the `PMEVTYPEPER<n>_EL0.MT` bit is set to 1, the PE only counts cycles on which no operation is issued from any thread.

#### ———— **Note** ————

The `PMCCNTR` register counts every processor cycle.

## D5.10.7 Meaningful ratios between common microarchitectural events

The architecture highlights some meaningful ratios that can be derived from the common microarchitectural events. Table D5-8 lists the highlighted ratios.

**Table D5-8 REFILL events and associated access events**

Numerator	Denominator	Ratio
0x0001 <a href="#">L1I_CACHE_REFILL</a>	0x0014 <a href="#">L1I_CACHE</a>	Attributable Level 1 instruction cache refill rate
0x0002 <a href="#">L1I_TLB_REFILL</a>	0x0026 <a href="#">L1I_TLB</a>	Attributable Level 1 instruction TLB refill rate
0x0003 <a href="#">L1D_CACHE_REFILL</a>	0x0004 <a href="#">L1D_CACHE</a>	Attributable Level 1 data or unified cache refill rate
0x0005 <a href="#">L1D_TLB_REFILL</a>	0x0025 <a href="#">L1D_TLB</a>	Attributable Level 1 data or unified TLB refill rate
0x0017 <a href="#">L2D_CACHE_REFILL</a>	0x0016 <a href="#">L2D_CACHE</a>	Attributable Level 2 data or unified cache refill rate
0x0028 <a href="#">L2I_CACHE_REFILL</a>	0x0027 <a href="#">L2I_CACHE</a>	Attributable Level 2 instruction cache refill rate
0x002A <a href="#">L3D_CACHE_REFILL</a>	0x002B <a href="#">L3D_CACHE</a>	Attributable Level 3 data or unified cache refill rate
0x002D <a href="#">L2D_TLB_REFILL</a>	0x002F <a href="#">L2D_TLB</a>	Attributable Level 2 data or unified TLB refill rate
0x002E <a href="#">L2I_TLB_REFILL</a>	0x0030 <a href="#">L2I_TLB</a>	Attributable Level 2 instruction TLB refill rate
0x0019 <a href="#">BUS_ACCESS</a>	0x001D <a href="#">BUS_CYCLES</a>	Attributable Bus accesses per cycle

## D5.10.8 Required events

PMUv3 requires that an implementation includes the following common events:

- 0x0000, [SW\\_INCR](#), Instruction architecturally executed, Condition code check pass, software increment.
- 0x0003, [L1D\\_CACHE\\_REFILL](#), Attributable Level 1 data cache refill.

### ———— Note ————

Event 0x0003 is only required if the implementation includes a Level 1 data or unified cache.

- 0x0004, [L1D\\_CACHE](#), Attributable Level 1 data cache access.

### ———— Note ————

Event 0x0004 is only required if the implementation includes a Level 1 data or unified cache.

- 0x0010, [BR\\_MIS\\_PRED](#), Mispredicted or not predicted branch speculatively executed.

### ———— Note ————

Event 0x0010 is only required if the implementation includes program-flow prediction. However, ARM recommends that the event is implemented as described in [Common microarchitectural event numbers on page D5-2163](#).

- 0x0011, [CPU\\_CYCLES](#), Cycle.
- 0x0012, [BR\\_PRED](#), Predictable branch speculatively executed.

### ———— Note ————

Event 0x0012 is only required if the implementation includes program-flow prediction. However, ARM recommends that the event is implemented as described in [Common microarchitectural event numbers on page D5-2163](#).

- At least one of:
  - 0x0008, [INST\\_RETIRED](#), Instruction architecturally executed.
  - 0x001B, [INST\\_SPEC](#), Operation speculatively executed.

———— **Note** ————

ARM strongly recommends that event 0x008 is implemented.

- When [ARMv8.1-PMU](#) is implemented:
  - 0x0023, [STALL\\_FRONTEND](#), No operation issued due to the frontend.
  - 0x0024, [STALL\\_BACKEND](#), No operation issued due to the backend.

## D5.10.9 IMPLEMENTATION DEFINED event numbers

For IMPLEMENTATION DEFINED event numbers, each counter is defined, independently, to either:

- Increment only once for each event.
- Count the duration for which an event occurs.

ARM recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common count numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, ARM recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

ARM strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Cumulative duration of stalls resulting from the holes in the instruction availability, separating out counts for key buffering points that might exist.
- Cumulative duration of data-dependent stalls, separating out counts for key dependency classes that might exist.
- Cumulative duration of stalls due to unavailability of execution resources, including, for example, write buffers, separating out counts for key resources that might exist.
- Missed superscalar issue opportunities, if relevant, separating out counts for key classes of issue that might exist.
- Miss rates for different levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a [PSTATE](#). {A, I, F} interrupt mask set to 1.
- Cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist.  
An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, for example by specifying a minimum latency for an event to be counted.
- Any other microarchitectural features that the implementer considers are valuable to count.

The IMPLEMENTATION DEFINED event numbers are 0x040 to 0x3FF. [Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events](#) lists the ARM recommended standardized numbering scheme for these events.

## D5.11 Performance Monitors Extension registers

The following section describes the Performance Monitors Extension registers.

The following subsections give general information about the Performance Monitors Extension registers, that apply for both Execution states:

- [Relationship between AArch32 and AArch64 Performance Monitors registers.](#)
- [Access permissions.](#)

[Performance Monitors Extension registers, functional group on page G4-4738](#) summarizes the Performance Monitors Extension registers in AArch32 state.

[Instructions for accessing non-debug System registers on page C5-323](#) summarizes the Performance Monitors Extension registers in AArch64 state.

### D5.11.1 Relationship between AArch32 and AArch64 Performance Monitors registers

[Table K11-2 on page K11-6284](#) lists the Performance Monitors register names for AArch32 and AArch64 states.

### D5.11.2 Access permissions

Each Exception level is able to control Performance Monitors System register accesses at lower Exception levels. The access control flow is:

1. At EL0:
  - Writes to [PMUSERENR](#) are UNDEFINED.
  - Reads and writes of [PMINTENSET](#) and [PMINTENCLR](#) are UNDEFINED.
  - If [PMUSERENR.EN](#) == 0:
    - If [PMUSERENR.SW](#) == 0 then writes to [PMSWINC](#) are trapped to EL1.
    - If [PMUSERENR.CR](#) == 0 then reads of [PMCCNTR](#) are trapped to EL1.
    - If [PMUSERENR.ER](#) == 0 then reads of [PMEVCNTR<n>](#) and [PMXVCNTR](#), and reads and writes of [PMSELR](#), are trapped to EL1.
    - Otherwise, for all other Performance Monitors registers, other than reads of [PMUSERENR](#), reads and writes are trapped to EL1.

———— **Note** ————

If [HCR.TGE](#)==1, then all exceptions that would be taken to EL1 are instead taken to EL2.

2. Otherwise, at EL1 and EL0 in Non-secure state, if EL2 is implemented:
  - If [HDCR.TPMCR](#) == 1 then accesses to [PMCR](#) are trapped to EL2.
  - If [HDCR.TPM](#) == 1 then accesses to all Performance Monitors registers, including [PMCR](#), are trapped to EL2.
3. Otherwise, at EL2, EL1 and EL0, if EL3 is implemented and using AArch64, and if [MDCR\\_EL3.TPM](#) == 1 then accesses to all Performance Monitors registers are trapped to EL3.

———— **Note** ————

These traps are not possible if EL3 is using AArch32.

4. Otherwise, the access is permitted.

———— **Note** ————

These traps and enables only apply to System register accesses using System register access instructions. For accesses through the optional memory-mapped or external debug interfaces, see [Access permissions for external views of the Performance Monitors on page I2-5739](#).

For details of the headings used in Table D5-9, see [Configurable instruction enables and disables, and trap controls](#) on page D1-1842. In addition, the following terms are used:

**Instruction** This shows the access instruction, read (MRS), write (MSR), or both (-). In AArch32 state, the equivalent instructions are MRC and MCR.

**Default access**

If the *Default access* is - then the access is trapped from EL0 to EL1 unless the [PMUSERENR enables](#) are set to 1.

**Resultant access permission**

This indicates the resulting access permission provided the enables at EL0 are enabled and the traps to EL2 or EL3 are disabled.

Table D5-9 shows the access permissions for System register accesses to the Performance Monitors registers.

**Table D5-9 Access permissions for the Performance Monitors System registers**

Register	Instruction	At EL0:		Traps from below to:		Resultant access permission
		Default access	PMUSERENR enables	EL2	EL3 <sup>a</sup>	
PMCR	-	-	EN	TPMCR or TPM	TPM	RW
PMCNTENSET	-	-	EN	TPM	TPM	RW
PMCNTENCLR	-	-	EN	TPM	TPM	RW
PMOVSCLR	-	-	EN	TPM	TPM	RW
PMSWINC	-	-	EN or SW	TPM	TPM	WO
PMSELR	-	-	EN or ER	TPM	TPM	RW
PMCEID0	-	-	EN	TPM	TPM	RO
PMCEID1	-	-	EN	TPM	TPM	RO
PMCCNTR	Read	-	EN or CR	TPM	TPM	RW
	Write	-	EN			
PMXEVTYPER	-	-	EN	TPM	TPM	RW
PMXVCNTR	Read	-	EN or ER	TPM	TPM	RW
	Write	-	EN			
PMUSERENR	Read	RO	-	TPM	TPM	RW
	Write	UND				
PMINTENSET	-	UND	-	TPM	TPM	RW
PMINTENCLR	-	UND	-	TPM	TPM	RW
PMOVSSET	-	-	EN	TPM	TPM	RW

**Table D5-9 Access permissions for the Performance Monitors System registers (continued)**

Register	Instruction	At EL0:		Traps from below to:		Resultant access permission
		Default access	<b>PMUSERENR enables</b>	EL2	EL3 <sup>a</sup>	
PMEVCNTR<n>	Read	-	EN or ER	TPM	TPM	RW
	Write	-	EN			
PMEVTYPER<n>	-	-	EN	TPM	TPM	RW
PMCCFILTR	-	-	EN	TPM	TPM	RW

a. Only if EL3 is using AArch64.

## Chapter D6

# The Generic Timer in AArch64 state

This chapter describes the implementation of the ARM Generic Timer. It includes an overview of the AArch64 System register interface to an ARM Generic Timer.

It contains the following sections:

- [About the Generic Timer on page D6-2180.](#)
- [The AArch64 view of the Generic Timer on page D6-2184.](#)

[Chapter G5 The Generic Timer in AArch32 state](#) describes the AArch32 view of the Generic Timer, and [Chapter I1 System Level Implementation of the Generic Timer](#) describes the system level implementation of the Generic Timer.

## D6.1 About the Generic Timer

Figure D6-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The *ARM Generic Interrupt Controller Architecture Specification* defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

Figure D6-1 Generic Timer example

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.

———— **Note** ————

The Generic Timer can also provide other components at a system level, but Figure D6-1 does not show any such components.

- Supports *virtual counters* that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Timers, that can trigger events after a period of time has passed. The timers:
  - Can be used as count-up or as count-down timers.
  - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure D6-1 shows as Timer\_0 or Timer\_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch64 state. Chapter G5 *The Generic Timer in AArch32 state* describes access to this component from AArch32 state.

A Generic Timer implementation must also include a memory-mapped system component. This component:

- Must provide the System counter shown in Figure D6-1
- Optionally, can provide timer components for use at a system level.

Chapter I1 *System Level Implementation of the Generic Timer* describes this memory-mapped component.

## D6.1.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

### The system counter

This provides a uniform view of system time, see [The system counter on page D6-2182](#). Because this must be implemented at the system level, it is accessed through [The system level memory-mapped implementation of the Generic Timer](#). However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

### PE implementations of the Generic Timer

Each PE implementation of the Generic Timer provides the following components:

- A physical counter, that gives access to the count value of the system counter.
- A virtual counter, that gives access to virtual time. In AArch64 state, the `CNTVOFF_EL2` register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
- A number of timers. In an implementation where all Exception levels are implemented and can use AArch64 state, the timers that are accessible from AArch64 state are:
  - An EL1 physical timer.
  - An EL2 physical timer.
  - An EL3 physical timer.
  - A virtual timer.

[The AArch64 view of the Generic Timer on page D6-2184](#) describes these components.

### The system level memory-mapped implementation of the Generic Timer

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into *frames*. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

#### The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, `CNTControlBase`.
- A status frame, `CNTReadBase`.

#### The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, `CNTCTLBase`.

#### Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the `CNTBaseN` frame.
- Optionally, provides an unprivileged view of the timer in the `CNTELOBaseN` frame.

*N* is the timer number, and the corresponding frame number, in the range 0-7.

[Chapter I1 System Level Implementation of the Generic Timer](#) describes these components.

## D6.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

<b>Width</b>	At least 56 bits wide. The value returned by any 64-bit read of the counter is zero-extended to 64 bits.
<b>Frequency</b>	Increments at a fixed frequency, typically in the range 1-50MHz. Can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving.
<b>Roll-over</b>	Roll-over time of not less than 40 years.
<b>Accuracy</b>	ARM does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period. Use of lower-frequency modes must not affect the implemented accuracy.
<b>Start-up</b>	Starts operating from zero.

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

The [CNTFRQ\\_EL0](#) register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information, see [Initializing and reading the system counter frequency](#).

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

### ———— Note ————

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. [Gray-count scheme for timer distribution scheme on page I1-5736](#) gives more information about this possibility.

## Initializing and reading the system counter frequency

The [CNTFRQ\\_EL0](#) register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the [CNTFRQ\\_EL0](#) register. Only software executing at the highest implemented Exception level can write to [CNTFRQ\\_EL0](#).

### ———— Note ————

The [CNTFRQ\\_EL0](#) register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the [CNTFRQ\\_EL0](#) register, to determine the current system counter frequency, in the following states:

- EL2.

- Secure and Non-secure EL1.
- When [CNTKCTL\\_EL1.EL0PCTEN](#) is set to 1, Secure and Non-secure EL0.

### Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see [Chapter I1 System Level Implementation of the Generic Timer](#).

## D6.2 The AArch64 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch64 state:

- [The physical counter](#).
- [The virtual counter on page D6-2185](#).
- [Event streams on page D6-2186](#).
- [Timers on page D6-2187](#).

### D6.2.1 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The `CNTPCT_EL0` register holds the current physical counter value.

#### Accessing the physical counter

Software with sufficient privilege can read `CNTPCT_EL0` using a 64-bit System register read.

`CNTPCT_EL0`:

- Is always accessible from EL3, Non-secure EL2 and Secure EL1 states.
- Is accessible from Non-secure EL1 only when `CNTHCTL_EL2.EL1PCTEN` is set to 1. When the value of `CNTHCTL_EL2.EL1PCTEN` is 0, any attempt to access `CNTPCT_EL0` from Non-secure EL1 is trapped to EL2.
- Is accessible from Secure EL0 state when the value of `CNTKCTL_EL1.EL0PCTEN` is 1. When the value of `CNTKCTL_EL1.EL0PCTEN` is 0, any attempt to access `CNTPCT_EL0` is UNDEFINED.
- Is accessible from Non-secure EL0 when the value of `CNTHCTL_EL2.EL1PCTEN` is 1 and the value of `CNTKCTL_EL1.EL0PCTEN` is 1. Otherwise:
  - When the value of `CNTKCTL_EL1.EL0PCTEN` is 0, any attempt to access `CNTPCT_EL0` from Non-secure EL0 generates an UNDEFINED exception.
  - When the value of `CNTKCTL_EL1.EL0PCTEN` is 1 and the value of `CNTHCTL_EL2.EL1PCTEN` is 0, any attempt to access `CNTPCT_EL0` from Non-secure EL0 is trapped to EL2.

Reads of `CNTPCT_EL0` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTPCT_EL0` must be read, an ISB is used to ensure that the read of `CNTPCT_EL0` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]
    CMP R1, #1
    BNE loop
    ISB              ; without this, the CNTPCT could be read before the memory location in [R2]
                    ; has had the value 1 written to it
    MRS R1, CNTPCT
```

## D6.2.2 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing at Non-secure EL1 or EL0, the virtual offset value relates to the current virtual machine.

The `CNTVOFF_EL2` register contains the virtual offset. `CNTVOFF_EL2` is only accessible from EL2 and EL3.

For more information, see *Status of the CNTVOFF register*.

The `CNTVCT_EL0` register holds the current virtual counter value.

### Accessing the virtual counter

Software with sufficient privilege can read `CNTVCT_EL0` using a 64-bit System register read.

`CNTVCT_EL0` is always accessible from Secure EL3, from Secure EL1 when EL3 is using AArch64, and from Non-secure EL1 and EL2.

In addition, when `CNTKCTL_EL1.EL0VCTEN` is set to 1, `CNTVCT_EL0` is accessible from EL0.

When `CNTKCTL_EL1.EL0VCTEN` is set to 0, any attempt to access `CNTVCT_EL0` from EL0 is UNDEFINED.

Reads of `CNTVCT_EL0` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTVCT_EL0` must be read, an ISB is used to ensure that the read of `CNTVCT_EL0` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]
    CMP R1, #1
    BNE loop
    ISB              ; without this, the CNTVCT could be read before the memory location in [R2]
                    ; has had the value 1 written to it
    MRS R1, CNTVCT
```

### Status of the CNTVOFF register

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the `CNTVOFF_EL2` register that defines the *virtual offset* between the physical count and the virtual count. `CNTVOFF_EL2` is only accessible at EL2 or above. If EL2 is not implemented, the virtual counter uses a fixed virtual offset of zero.

### D6.2.3 Event streams

An implementation that includes the Generic Timer can use the system counter to generate one or more *event streams*, to generate periodic wake-up events as part of the mechanism described in [Wait for Event mechanism and Send event](#) on page D1-1879.

#### ————— Note —————

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

An event stream is configured by:

- Selecting which bit, from the bottom 16 bits of a counter, triggers the event. This determines the frequency of the events in the stream.
- Selecting whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

The [CNTKCTL\\_EL1](#).{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the virtual counter.

In all implementations, the [CNTHCTL\\_EL2](#).{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the physical counter.

The operation of an event stream is as follows:

- The pseudocode variables PreviousCNTVCT and PreviousCNPCT are initialized as:  

```
// Variables used for generation of the timer event stream.
bits(64) PreviousCNTVCT = bits(64) UNKNOWN;
bits(64) PreviousCNPCT = bits(64) UNKNOWN;
```
- The pseudocode functions TestEventCNTV() and TestEventCNP() are called on each cycle of the PE clock.
- The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNP():

```
// TestEventCNTx()
// =====

// Template for the TestEventCNTV() and TestEventCNP() functions
// Describes operation when all Exception Levels are using AArch64:
// CNTxCT_EL0 is CNTVCT_EL0 or CNTPCT_EL0 64-bit count value
// CNTx_CTL_EL0 is CNTV_CTL_EL0 or CNTP_CTL_EL0 Control register
// PreviousCNTxCT_EL0 is PreviousCNTVCT_EL0 or PreviousCNPCT_EL0

TestEventCNTx()
    if CNTx_CTL_EL0.EVNTEN == '1' then
        n = UInt(CNTx_CTL_EL0.EVNTI);
        SampleBit = CNTxCT_EL0<n>;
        PreviousBit = PreviousCNTxCT_EL0<n>;

        if CNTx_CTL_EL0.EVNTDIR == '0' then
            if PreviousBit == '0' && SampleBit == '1' then EventRegisterSet();
        else
            if PreviousBit == '1' && SampleBit == '0' then EventRegisterSet();

    PreviousCNTxCT_EL0 = CNTxCT_EL0;

    return;
```

## D6.2.4 Timers

In an implementation of the Generic Timer that includes EL3, if EL3 can use AArch64, the following timers are implemented:

- An EL1 physical timer, that:
  - In Secure state, can be accessed from EL1.
  - In Non-secure state, can be accessed from EL1 unless those accesses are trapped to EL2.
 When this timer can be accessed from EL1, an EL1 control determines whether it can be accessed from EL0.
- A Non-secure EL2 physical timer.
- A Secure EL3 physical timer. An EL3 control determines whether this register is accessible from Secure EL1.
- A virtual timer.

The output of each implemented timer:

- Provides an output signal to the system.
- If the PE interfaces to a *Generic Interrupt Controller* (GIC), signals a *Private Peripheral Interrupt* (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer:

- Is based around a 64-bit CompareValue that provides a 64-bit unsigned upcounter.
- Provides an alternative view of the CompareValue, called the TimerValue, that appears to operate as a 32-bit downcounter.
- Has, in addition, a 32-bit Control register.

**Table D6-1 Timer registers summary for the Generic Timer**

Timer <sup>a</sup> register	EL1 physical timer	EL2 physical timer	EL3 physical timer	EL1 virtual timer	EL2 virtual timer
CV	CNTP_CVAL_EL0	CNTHP_CVAL_EL2	CNTPS_CVAL_EL1	CNTV_CVAL_EL0	CNTHV_CVAL_EL2 <sup>b</sup>
TV	CNTP_TVAL_EL0	CNTHP_TVAL_EL2	CNTPS_TVAL_EL1	CNTV_TVAL_EL0	CNTHV_TVAL_EL2 <sup>b</sup>
Control	CNTP_CTL_EL0	CNTHP_CTL_EL2	CNTPS_CTL_EL1	CNTV_CTL_EL0	CNTHV_CTL_EL2 <sup>b</sup>

a. In this column, CV indicates the ControlValue register, and TV indicates the TimerValue register.

b. Only when both the implementation includes [ARMv8.1-VHE](#) and the value of [HCR\\_EL2.E2H](#) is 1.

The following sections describe:

- [Operation of the CompareValue views of the timers](#)
- [Operation of the TimerValue views of the timers on page D6-2188.](#)

### Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, [CNTP\\_CTL\\_EL0](#), [CNTHP\\_CTL\\_EL2](#), [CNTPS\\_CTL\\_EL1](#), or [CNTV\\_CTL\\_EL0](#). For [CNTP\\_CTL\\_EL0](#), the asserted interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch32 register [CNTP\\_CTL](#).

The operation of this view of a timer is:

$$\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) \geq 0)$$

Where:

TimerConditionMet      Is TRUE if the timer condition for this counter is met, and FALSE otherwise.

Counter The physical counter value, that can be read from the [CNTPCT\\_EL0](#) register.

———— **Note** ————

The virtual counter value, that can be read from the [CNTVCT\\_EL0](#) register, is the value:  
(Counter - Offset)

Offset For a physical timer it is zero, and for the virtual timer it is the virtual offset, held in the [CNTVOFF\\_EL2](#) register.

CompareValue The value of the appropriate CompareValue register, [CNTP\\_CVAL\\_EL0](#), [CNTHP\\_CVAL\\_EL2](#), [CNTPS\\_CVAL\\_EL1](#), or [CNTV\\_CVAL\\_EL0](#).

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

———— **Note** ————

This means that a timer with a CompareValue of, or close to, 0xFFFF\_FFFF\_FFFF\_FFFF might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

## Operation of the TimerValue views of the timers

The TimerValue view of a timer appears to operate as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, [CNTP\\_CTL\\_EL0](#), [CNTHP\\_CTL\\_EL2](#), [CNTPS\\_CTL\\_EL1](#), or [CNTV\\_CTL\\_EL0](#).

This view of a timer depends on the following behavior of accesses to TimerValue registers:

**Reads**  $\text{TimerValue} = (\text{CompareValue} - (\text{Counter} - \text{Offset})) [31:0]$

**Writes**  $\text{CompareValue} = ((\text{Counter} - \text{Offset}) [63:0] + \text{SignExtend}(\text{TimerValue})) [63:0]$

Where the arguments other than TimerValue have the definitions used in *Operation of the CompareValue views of the timers on page D6-2187*, and in addition:

TimerValue The value of a TimerValue register, [CNTP\\_TVAL\\_EL0](#), [CNTHP\\_TVAL\\_EL2](#), [CNTPS\\_TVAL\\_EL1](#), or [CNTV\\_TVAL\\_EL0](#).

In this view of a timer, values are signed in standard two's complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.

———— **Note** ————

- *Operation of the CompareValue views of the timers on page D6-2187* gives a strict definition of TimerConditionMet. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from 0x80000000, the TimerValue view can be used as giving an effect equivalent to:  
 $\text{TimerConditionMet} = (\text{TimerValue} \leq 0)$
- Programming TimerValue to a negative number with magnitude greater than (Counter-Offset) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.

# Chapter D7

## **AArch64 System Register Descriptions**

This chapter defines the AArch64 System registers. It contains the following sections:

- *About the AArch64 System registers* on page D7-2190.
- *General system control registers* on page D7-2198.
- *Debug registers* on page D7-2554.
- *Performance Monitors registers* on page D7-2629.
- *Generic Timer registers* on page D7-2672.

## D7.1 About the AArch64 System registers

The following sections describe common features of the AArch64 registers:

- [General information about the AArch64 System registers.](#)
- [Fixed values in the System register descriptions.](#)
- [General behavior of accesses to the AArch64 System registers.](#)
- [Principles of the ID scheme for fields in ID registers on page D7-2195.](#)

### D7.1.1 General information about the AArch64 System registers

The structure of the System register descriptions has changed from that used in *ARM® Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile*, Issue A.j and earlier:

- Information about the accessibility of the register from different Exception levels is given in the Accessibility section, that is the last but one section of a register description.
- Information about the traps and enables that apply to the register is given in the Traps and Enables section, that is the last section of a register description.

The information in these sections can depend on:

- The mnemonic that is used to access the register.
- The value of one or more of the controls {E2H, TGE, NS}.

These controls are:

- [HCR\\_EL2](#).{E2H, TGE} fields.
- [SCR\\_EL3](#).NS field.

#### ———— Note ————

- These changes mean that the register descriptions can address:
  - Cases where a single register is accessible using more than one mnemonic, in different contexts, and that the accessibility can depend on the mnemonic that is used and the context in which it is used.
  - Cases where a single mnemonic can address different registers, depending on the context, and that the accessibility can also depend on the context.

These changes are needed to describe System register behaviors associated with the Virtualization Host Extension described in [Virtualization Host Extensions on page D4-2098](#). However, they also improve the representation of many ARMv8.0 register descriptions.

- This change to the structure of System register descriptions does not apply to the description of memory-mapped registers such as those described in [Chapter H9 External Debug Register Descriptions](#).

### D7.1.2 Fixed values in the System register descriptions

See [Fixed values in AArch64 instruction and System register descriptions on page C2-151](#). This section defines how the glossary terms [RAZ](#), [RES0](#), [RAO](#), and [RES1](#) can be represented in the System register descriptions.

#### System register width

The register descriptions in this chapter describe each register as either a *32-bit register* or a *64-bit register*. For registers described as 32-bit registers, the upper bits, bits[63:32], are RES0.

### D7.1.3 General behavior of accesses to the AArch64 System registers

The following subsections give general information about the behavior of accesses to the System registers:

- [Reset behavior of AArch64 System registers on page D7-2191.](#)
- [Synchronization requirements for AArch64 System registers on page D7-2191.](#)

## Reset behavior of AArch64 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.
- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch64, see:

- [PE state on reset to AArch64 state on page D1-1796](#).
- The appropriate Trace architecture specification, for the Trace System registers.

For a PE reset into an Exception level that is using AArch64, the architecture defines which AArch64 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and [PE state on reset to AArch64 state on page D1-1796](#) summarizes these architectural requirements. Otherwise, RW registers that have a meaningful reset value reset to an architecturally UNKNOWN value.

### ———— Note ————

When the PE resets into an Exception level that is using AArch32, no PE state that relates to execution in AArch64 state is accessible until another reset causes the Execution state to change to AArch64. Therefore, on a reset into AArch32 state, PE state that relates only to execution in AArch64 state cannot have a meaningful reset value.

## Pseudocode description of resetting System registers

The `AArch64.ResetSystemRegisters()` pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and [PE state on reset to AArch64 state on page D1-1796](#).

### ———— Note ————

For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

## Synchronization requirements for AArch64 System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

- Any data dependencies between the instructions, including read-after-read dependencies, are respected.
- The reads to the register do not occur earlier than the most recent [Context synchronization event](#) to its architectural position in the instruction stream.

### ———— Note ————

In particular, the values read from System registers that hold self-incrementing counts, such as the performance counters or the Generic Timer counter or timers, could be accessed from any time after the previous [Context synchronization event](#). For example, where a memory access is used to communicate a read of such counters, an ISB

must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the write being completed, and the read of the Generic Timer counter, if it is necessary that the Generic Timer counter returns a count value after the memory communication.

---

Direct writes using the instructions in [Table C5-6 on page C5-324](#) require synchronization before software can rely on the effects of changes to the System registers to affect instructions appearing in program order after the direct write to the System register. Direct writes to these registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

- All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other
- All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.
- Any System register access that an ARM *Architecture Specification* or equivalent specification defines as not requiring synchronization.

Explicit synchronization occurs as a result of a [Context synchronization event](#), which is one of the following events:

- Execution of an ISB instruction.
- Exception entry.
- Exception return.
- Execution of a DCPS instruction in Debug state.
- Execution of a DRPS instruction in Debug state.
- Exit from Debug state.

---

**Note**

---

The ISB and exception entry events are applicable both in Debug state and in Non-debug state.

---

Conceptually, explicit synchronization occurs as the first step of each of these events, so that if the event uses state that has previously been changed but was not synchronized by the time of the event, the event is guaranteed to use the state as if it had been synchronized.

---

**Note**

---

This explicit synchronization applies as the first step of the execution of the events, and does not apply to any effect of System registers that apply to the fetch and decode of the instructions that cause these events, such as breakpoints or changes to the translation table.

---

In addition, any system instructions that cause a write to a System register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that System register.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

- [ISR\\_EL1](#).
- The Generic Timer registers, that is, [CNTPCT\\_EL0](#) and [CNTVCT\\_EL0](#), and the Counter registers [CNTPTVAL\\_EL0](#), [CNTV\\_TVAL\\_EL0](#), [CNTHP\\_TVAL\\_EL2](#), and [CNTPTS\\_TVAL\\_EL1](#).
- [DBGCLAIMCLR\\_EL1](#).
- The PMU Counters, that is, [PMCCNTR\\_EL0](#), [PMEVCNTR<n>\\_EL0](#), [PMXVCNTR\\_EL0](#), [PMOVSCLR\\_EL0](#), and [PMOVSSET\\_EL0](#).
- The Debug Communications Channel registers, that is, [DBGDTRRX\\_EL0](#), [DBGDTR\\_EL0](#), and [MDCCSR\\_EL0](#).

All other direct reads of System registers can occur in any order if synchronization has not been performed.

[Table D7-1](#) describes the synchronization requirements between two successive read or write accesses to the same register, where the ordering of the read or write accesses is:

1. Program order, in the event that both the reads or writes are caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes at the PE relative to the execution of instructions that cause reads or writes.
3. The order of arrival of asynchronous reads and writes at the PE relative to each other.

**Table D7-1 Synchronization requirements**

First read-write	Second read-write	Synchronization requirement
Direct read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None, see <a href="#">Notes</a>
Direct write	Direct read	None
	Direct write	None
	Indirect read	Required
	Indirect write	None, see <a href="#">Notes</a>
Indirect read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None
Indirect write	Direct read	Required, see <a href="#">Notes</a>
	Direct write	None, see <a href="#">Notes</a>
	Indirect read	Required, see <a href="#">Notes</a>
	Indirect write	None, see <a href="#">Notes</a>

## Notes

The terms Direct read, Direct write, Indirect read, and Indirect write, as used in [Table D7-1](#), are defined as follows:

**Direct read** Where software uses a System register access instruction to read the register, see both:

- [Instructions for accessing non-debug System registers on page C5-323.](#)
- [Instructions for accessing debug System registers on page C5-322.](#)

Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

**Direct write** Where software uses a System register access instruction to write to the register, see both:

- [Instructions for accessing non-debug System registers on page C5-323.](#)
- [Instructions for accessing debug System registers on page C5-322.](#)

Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

**Indirect read** Where an instruction uses a System register to establish operating conditions for the instruction, for example, the `TTBR_ELx` address or whether memory accesses are forced to be Non-cacheable. This includes situations where the contents of one System register selects what value is read or written using a different register. Indirect reads also include reads of the System register by external agents such as debuggers. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.

**Indirect write** Where a System register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of an external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

———— **Note** —————

Since an exception is context synchronizing, registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization.

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.

Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Indirect writes caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, to the registers shown in [Table D7-2 on page D7-2195](#), are required to be observable to:

- Direct reads in finite time without explicit synchronization.

- Subsequent indirect reads without explicit synchronization.

**Table D7-2 Registers with a guarantee of observability, VMSAv8-64**

Registers	Notes
<a href="#">ISR_EL1</a>	Interrupt Status Register
<a href="#">DBGCLAIMCLR_EL1</a> , <a href="#">DBGCLAIMSET_EL1</a>	Debug CLAIM registers
<a href="#">CNTPCT_EL0</a> , <a href="#">CNTVCT_EL0</a> , <a href="#">CNTPT_TVAL_EL0</a> , <a href="#">CNTV_TVAL_EL0</a> , <a href="#">CNTHTP_TVAL_EL2</a> , <a href="#">CNTPTS_TVAL_EL1</a>	Generic Timer registers
<a href="#">PMCCNTR_EL0</a> , <a href="#">PMEVCNTR&lt;n&gt;_EL0</a> , <a href="#">PMXEVNTR_EL0</a> , <a href="#">PMOVSCLR_EL0</a> , <a href="#">PMOVSSET_EL0</a>	PMU Counters
<a href="#">DBGDTRTX_EL0</a> , <a href="#">DBGDTRRX_EL0</a> , <a href="#">DBGDTR_EL0</a> , and the DCC flags in <a href="#">MDCCSR_EL0</a> and <a href="#">EDSCR</a>	Debug Communication Channel registers
<a href="#">EDSCR</a> .PipeAdv	External Debug Status and Control Register PipeAdv field

In addition to the requirements shown in [Table D7-2](#):

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
  - [OSLAR\\_EL1](#). [OSLAR\\_EL1](#) is indirectly read to determine whether the subsequent access is permitted.
  - [EDLAR](#), if implemented. [EDLAR](#) is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

———— **Note** —————

This requirement is stricter than the general requirement for the observability of indirect writes.

- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See [DCC and ITR access in Debug state on page H4-5513](#).

———— **Note** —————

- The provision of explicit synchronization requirements to System registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.
- Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.
- While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.

## D7.1.4 Principles of the ID scheme for fields in ID registers

The ARM architecture specifies a number of *ID registers* that are characterized as comprising a set of 4-bit *ID fields*. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. [ID registers to which this scheme applies on page D7-2197](#) identifies the set of ID registers.

---

**Note**

These fields are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.

---

To provide forward compatibility, software can rely on the features of these fields that are described in this section.

The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of 0x1 indicates the presence of some instructions, then the value 0x2 will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```
if (value >= number) {    // do something that relies on the value of the feature}
```

For ID fields where the value 0x0 defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value 0xF indicates that the feature is not implemented.
- The field value 0x0 indicates that the feature is implemented.
- Software that depends on the feature can use the test:

```
if value >= 0 {  
    // Software features that depend on the presence of the hardware feature  
}
```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a *fractional* field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle, a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. [Example D7-1](#) shows the use of such a field.

#### Example D7-1 Example of the use of a fractional field

---

For a field describing some class of functionality:

- The value 0x1 was defined as indicating that item A is present.
- The value 0x2 was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value 0x1 when A and B only are present. This fractional field is valid only when the original ID field has the value 0x1.

This approach means that:

- Software that depends on the test if (value >= 0x2) can rely on features A, B, and C being present,
- Software that depends on the test if (value >= 0x1) can rely on feature A being present.
- If new software needs to check only that features A and B are present, then it can test:

```
if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {  
    // Software features that depend on A and B only  
}
```

---

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

## ID registers to which this scheme applies

This scheme applies to the following registers:

### AArch64 System registers

- The AArch64 views of the AArch32 feature ID registers given by:
  - The AArch32 Auxiliary Feature register [ID\\_AFR0\\_EL1](#).
  - The AArch32 Processor Feature registers [ID\\_PFR0\\_EL1](#) and [ID\\_PFR1\\_EL1](#).
  - The AArch32 Debug Feature register [ID\\_DFR0\\_EL1](#).
  - The AArch32 Memory Model Feature registers [ID\\_MMFR0\\_EL1](#), [ID\\_MMFR1\\_EL1](#), [ID\\_MMFR2\\_EL1](#), [ID\\_MMFR3\\_EL1](#), and [ID\\_MMFR4\\_EL1](#).
  - The AArch32 Instruction Set Attribute registers [ID\\_ISAR0\\_EL1](#), [ID\\_ISAR1\\_EL1](#), [ID\\_ISAR2\\_EL1](#), [ID\\_ISAR3\\_EL1](#), [ID\\_ISAR4\\_EL1](#), and [ID\\_ISAR5\\_EL1](#).
  - The AArch32 Media and VFP Feature registers [MVFR0\\_EL1](#), [MVFR1\\_EL1](#), and [MVFR2\\_EL1](#).
- The AArch64 Auxiliary Feature registers [ID\\_AA64AFR0\\_EL1](#) and [ID\\_AA64AFR1\\_EL1](#).
- The AArch64 Processor Feature registers [ID\\_AA64PFR0\\_EL1](#) and [ID\\_AA64PFR1\\_EL1](#).
- The AArch64 Debug Feature registers [ID\\_AA64DFR0\\_EL1](#) and [ID\\_AA64DFR1\\_EL1](#).
- The AArch64 Memory Model Feature registers [ID\\_AA64MMFR0\\_EL1](#), [ID\\_AA64MMFR1\\_EL1](#), and [ID\\_AA64MMFR2\\_EL1](#).
- The AArch64 Instruction Set Attribute registers [ID\\_AA64ISAR0\\_EL1](#) and [ID\\_AA64ISAR1\\_EL1](#).

### AArch32 System registers

- The AArch32 Auxiliary Feature register [ID\\_AFR0](#).
- The AArch32 Processor Feature registers [ID\\_PFR0](#) and [ID\\_PFR1](#).
- The AArch32 Debug Feature register [ID\\_DFR0](#).
- The AArch32 Memory Model Feature registers [ID\\_MMFR0](#), [ID\\_MMFR1](#), [ID\\_MMFR2](#), [ID\\_MMFR3](#), and [ID\\_MMFR4](#).
- The AArch32 Instruction Set Attribute registers [ID\\_ISAR0](#), [ID\\_ISAR1](#), [ID\\_ISAR2](#), [ID\\_ISAR3](#), [ID\\_ISAR4](#), and [ID\\_ISAR5](#).
- The AArch32 Media and VFP Feature registers [MVFR0](#), [MVFR1](#), and [MVFR2](#).

### Memory-mapped registers

- The External Debug Processor Feature register [EDPFR](#).
- The External Debug Feature register [EDDFR](#).

## D7.2 General system control registers

This section lists the System registers in AArch64 that are not part of one of the other listed groups.

## D7.2.1 ACTLR\_EL1, Auxiliary Control Register (EL1)

The ACTLR\_EL1 characteristics are:

### Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

### Note

ARM recommends the contents of this register have no effect on the PE when [HCR\\_EL2](#).{E2H, TGE} is {1, 1}, and instead the configuration and control fields are provided by the [ACTLR\\_EL2](#) register. This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

### Configurations

AArch64 System register ACTLR\_EL1[31:0] is architecturally mapped to AArch32 System register [ACTLR](#).

AArch64 System register ACTLR\_EL1[63:32] is architecturally mapped to AArch32 System register [ACTLR2](#).

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

ACTLR\_EL1 is a 64-bit register.

### Field descriptions

The ACTLR\_EL1 bit assignments are:

### IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

### Accessing the ACTLR\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
ACTLR_EL1	11	000	0001	0000	001

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
0	0	1	-	RW	RW	RW
0	1	1	-	n/a	RW	RW
1	0	1	-	RW	RW	RW
1	1	1	-	n/a	RW	RW

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TACR](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2.TACR](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.

## D7.2.2 ACTLR\_EL2, Auxiliary Control Register (EL2)

The ACTLR\_EL2 characteristics are:

### Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

### Note

ARM recommends the contents of this register are updated to apply to EL0 when [HCR\\_EL2](#).{E2H, TGE} is {1, 1}, gaining configuration and control fields from the [ACTLR\\_EL1](#). This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

### Configurations

AArch64 System register ACTLR\_EL2[31:0] is architecturally mapped to AArch32 System register [HACTLR](#).

AArch64 System register ACTLR\_EL2[63:32] is architecturally mapped to AArch32 System register [HACTLR2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

ACTLR\_EL2 is a 64-bit register.

### Field descriptions

The ACTLR\_EL2 bit assignments are:

### IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

### Accessing the ACTLR\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
ACTLR_EL2	11	100	0001	0000	001

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
0	0	1	-	-	RW	RW
0	1	1	-	n/a	RW	RW
1	0	1	-	-	RW	RW
1	1	1	-	n/a	RW	RW

### D7.2.3 ACTLR\_EL3, Auxiliary Control Register (EL3)

The ACTLR\_EL3 characteristics are:

#### Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL3.

#### Configurations

RW fields in this register reset to architecturally UNKNOWN values.

#### Attributes

ACTLR\_EL3 is a 64-bit register.

#### Field descriptions

The ACTLR\_EL3 bit assignments are:

#### IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

#### Accessing the ACTLR\_EL3

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
ACTLR_EL3	11	110	0001	0000	001

#### Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

D7.2.4 AFSR0\_EL1, Auxiliary Fault Status Register 0 (EL1)

The AFSR0\_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

Configurations

AArch64 System register AFSR0\_EL1 is architecturally mapped to AArch32 System register [ADFSR](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AFSR0\_EL1 is a 32-bit register.

Field descriptions

The AFSR0\_EL1 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AFSR0\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AFSR0_EL1	11	000	0101	0001	000
AFSR0_EL12	11	101	0101	0001	000

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
AFSR0_EL1	x	x	0	-	RW	n/a	RW
AFSR0_EL1	0	0	1	-	RW	RW	RW
AFSR0_EL1	0	1	1	-	n/a	RW	RW
AFSR0_EL1	1	0	1	-	RW	<a href="#">AFSR0_EL2</a>	RW
AFSR0_EL1	1	1	1	-	n/a	<a href="#">AFSR0_EL2</a>	RW
AFSR0_EL12	x	x	0	-	-	n/a	-
AFSR0_EL12	0	0	1	-	-	-	-
AFSR0_EL12	0	1	1	-	n/a	-	-
AFSR0_EL12	1	0	1	-	-	RW	RW
AFSR0_EL12	1	1	1	-	n/a	RW	RW

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic AFSR0\_EL1 or AFSR0\_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

### D7.2.5 AFSR0\_EL2, Auxiliary Fault Status Register 0 (EL2)

The AFSR0\_EL2 characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

**Configurations**

AArch64 System register AFSR0\_EL2 is architecturally mapped to AArch32 System register [HADFSR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AFSR0\_EL2 is a 32-bit register.

**Field descriptions**

The AFSR0\_EL2 bit assignments are:

**IMPLEMENTATION DEFINED, bits [31:0]**

IMPLEMENTATION DEFINED.

**Accessing the AFSR0\_EL2**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AFSR0_EL2	11	100	0101	0001	000
AFSR0_EL1	11	000	0101	0001	000

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
AFSR0_EL2	x	x	0	-	-	n/a	RW
AFSR0_EL2	0	0	1	-	-	RW	RW
AFSR0_EL2	0	1	1	-	n/a	RW	RW
AFSR0_EL2	1	0	1	-	-	RW	RW
AFSR0_EL2	1	1	1	-	n/a	RW	RW
AFSR0_EL1	x	x	0	-	<a href="#">AFSR0_EL1</a>	n/a	<a href="#">AFSR0_EL1</a>
AFSR0_EL1	0	0	1	-	<a href="#">AFSR0_EL1</a>	<a href="#">AFSR0_EL1</a>	<a href="#">AFSR0_EL1</a>
AFSR0_EL1	0	1	1	-	n/a	<a href="#">AFSR0_EL1</a>	<a href="#">AFSR0_EL1</a>
AFSR0_EL1	1	0	1	-	<a href="#">AFSR0_EL1</a>	RW	<a href="#">AFSR0_EL1</a>
AFSR0_EL1	1	1	1	-	n/a	RW	<a href="#">AFSR0_EL1</a>

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL2 using the mnemonic AFSR0\_EL2 or AFSR0\_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## D7.2.6 AFSR0\_EL3, Auxiliary Fault Status Register 0 (EL3)

The AFSR0\_EL3 characteristics are:

### Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

### Configurations

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

AFSR0\_EL3 is a 32-bit register.

### Field descriptions

The AFSR0\_EL3 bit assignments are:

### IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

### Accessing the AFSR0\_EL3

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AFSR0_EL3	11	110	0101	0001	000

### Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

## D7.2.7 AFSR1\_EL1, Auxiliary Fault Status Register 1 (EL1)

The AFSR1\_EL1 characteristics are:

### Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

### Configurations

AArch64 System register AFSR1\_EL1 is architecturally mapped to AArch32 System register [AIFSR](#).

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

AFSR1\_EL1 is a 32-bit register.

### Field descriptions

The AFSR1\_EL1 bit assignments are:

### IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

### Accessing the AFSR1\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AFSR1_EL1	11	000	0101	0001	001
AFSR1_EL12	11	101	0101	0001	001

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
AFSR1_EL1	x	x	0	-	RW	n/a	RW
AFSR1_EL1	0	0	1	-	RW	RW	RW
AFSR1_EL1	0	1	1	-	n/a	RW	RW
AFSR1_EL1	1	0	1	-	RW	<a href="#">AFSR1_EL2</a>	RW
AFSR1_EL1	1	1	1	-	n/a	<a href="#">AFSR1_EL2</a>	RW
AFSR1_EL12	x	x	0	-	-	n/a	-
AFSR1_EL12	0	0	1	-	-	-	-
AFSR1_EL12	0	1	1	-	n/a	-	-
AFSR1_EL12	1	0	1	-	-	RW	RW
AFSR1_EL12	1	1	1	-	n/a	RW	RW

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic AFSR1\_EL1 or AFSR1\_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

## D7.2.8 AFSR1\_EL2, Auxiliary Fault Status Register 1 (EL2)

The AFSR1\_EL2 characteristics are:

### Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

### Configurations

AArch64 System register AFSR1\_EL2 is architecturally mapped to AArch32 System register [HAIFSR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

AFSR1\_EL2 is a 32-bit register.

### Field descriptions

The AFSR1\_EL2 bit assignments are:

### IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

### Accessing the AFSR1\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AFSR1_EL2	11	100	0101	0001	001
AFSR1_EL1	11	000	0101	0001	001

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
AFSR1_EL2	x	x	0	-	-	n/a	RW
AFSR1_EL2	0	0	1	-	-	RW	RW
AFSR1_EL2	0	1	1	-	n/a	RW	RW
AFSR1_EL2	1	0	1	-	-	RW	RW
AFSR1_EL2	1	1	1	-	n/a	RW	RW
AFSR1_EL1	x	x	0	-	<a href="#">AFSR1_EL1</a>	n/a	<a href="#">AFSR1_EL1</a>
AFSR1_EL1	0	0	1	-	<a href="#">AFSR1_EL1</a>	<a href="#">AFSR1_EL1</a>	<a href="#">AFSR1_EL1</a>
AFSR1_EL1	0	1	1	-	n/a	<a href="#">AFSR1_EL1</a>	<a href="#">AFSR1_EL1</a>
AFSR1_EL1	1	0	1	-	<a href="#">AFSR1_EL1</a>	RW	<a href="#">AFSR1_EL1</a>
AFSR1_EL1	1	1	1	-	n/a	RW	<a href="#">AFSR1_EL1</a>

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL2 using the mnemonic AFSR1\_EL2 or AFSR1\_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## D7.2.9 AFSR1\_EL3, Auxiliary Fault Status Register 1 (EL3)

The AFSR1\_EL3 characteristics are:

### Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

### Configurations

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

AFSR1\_EL3 is a 32-bit register.

### Field descriptions

The AFSR1\_EL3 bit assignments are:

### IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

### Accessing the AFSR1\_EL3

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AFSR1_EL3	11	110	0101	0001	001

### Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

## D7.2.10 AIDR\_EL1, Auxiliary ID Register

The AIDR\_EL1 characteristics are:

### Purpose

Provides IMPLEMENTATION DEFINED identification information.

The value of this register must be interpreted in conjunction with the value of [MIDR\\_EL1](#).

### Configurations

AArch64 System register AIDR\_EL1 is architecturally mapped to AArch32 System register [AIDR](#).

### Attributes

AIDR\_EL1 is a 32-bit register.

### Field descriptions

The AIDR\_EL1 bit assignments are:

### IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

### Accessing the AIDR\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AIDR_EL1	11	001	0000	0000	111

### Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TID1](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2.TID1](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

### D7.2.11 AMAIR\_EL1, Auxiliary Memory Attribute Indirection Register (EL1)

The AMAIR\_EL1 characteristics are:

#### Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by [MAIR\\_EL1](#).

#### Configurations

AArch64 System register AMAIR\_EL1[31:0] is architecturally mapped to AArch32 System register [AMAIR0](#).

AArch64 System register AMAIR\_EL1[63:32] is architecturally mapped to AArch32 System register [AMAIR1](#).

RW fields in this register reset to architecturally UNKNOWN values.

#### Attributes

AMAIR\_EL1 is a 64-bit register.

#### Field descriptions

The AMAIR\_EL1 bit assignments are:

AMAIR\_EL1 is permitted to be cached in a TLB.

#### IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

#### Accessing the AMAIR\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AMAIR_EL1	11	000	1010	0011	000
AMAIR_EL12	11	101	1010	0011	000

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
AMAIR_EL1	x	x	0	-	RW	n/a	RW
AMAIR_EL1	0	0	1	-	RW	RW	RW
AMAIR_EL1	0	1	1	-	n/a	RW	RW
AMAIR_EL1	1	0	1	-	RW	<a href="#">AMAIR_EL2</a>	RW
AMAIR_EL1	1	1	1	-	n/a	<a href="#">AMAIR_EL2</a>	RW
AMAIR_EL12	x	x	0	-	-	n/a	-
AMAIR_EL12	0	0	1	-	-	-	-
AMAIR_EL12	0	1	1	-	n/a	-	-
AMAIR_EL12	1	0	1	-	-	RW	RW
AMAIR_EL12	1	1	1	-	n/a	RW	RW

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic [AMAIR\\_EL1](#) or [AMAIR\\_EL12](#) are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

### D7.2.12 AMAIR\_EL2, Auxiliary Memory Attribute Indirection Register (EL2)

The AMAIR\_EL2 characteristics are:

#### Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by [MAIR\\_EL2](#).

#### Configurations

AArch64 System register AMAIR\_EL2[31:0] is architecturally mapped to AArch32 System register [HMAIR0](#).

AArch64 System register AMAIR\_EL2[63:32] is architecturally mapped to AArch32 System register [HMAIR1](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

#### Attributes

AMAIR\_EL2 is a 64-bit register.

#### Field descriptions

The AMAIR\_EL2 bit assignments are:

AMAIR\_EL2 is permitted to be cached in a TLB.

#### IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

#### Accessing the AMAIR\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AMAIR_EL2	11	100	1010	0011	000
AMAIR_EL1	11	000	1010	0011	000

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
AMAIR_EL2	x	x	0	-	-	n/a	RW
AMAIR_EL2	0	0	1	-	-	RW	RW
AMAIR_EL2	0	1	1	-	n/a	RW	RW
AMAIR_EL2	1	0	1	-	-	RW	RW
AMAIR_EL2	1	1	1	-	n/a	RW	RW
AMAIR_EL1	x	x	0	-	AMAIR_EL1	n/a	AMAIR_EL1
AMAIR_EL1	0	0	1	-	AMAIR_EL1	AMAIR_EL1	AMAIR_EL1
AMAIR_EL1	0	1	1	-	n/a	AMAIR_EL1	AMAIR_EL1
AMAIR_EL1	1	0	1	-	AMAIR_EL1	RW	AMAIR_EL1
AMAIR_EL1	1	1	1	-	n/a	RW	AMAIR_EL1

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL2 using the mnemonic AMAIR\_EL2 or AMAIR\_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

### D7.2.13 AMAIR\_EL3, Auxiliary Memory Attribute Indirection Register (EL3)

The AMAIR\_EL3 characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by [MAIR\\_EL3](#).

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMAIR\_EL3 is a 64-bit register.

**Field descriptions**

The AMAIR\_EL3 bit assignments are:

AMAIR\_EL3 is permitted to be cached in a TLB.

**IMPLEMENTATION DEFINED, bits [63:0]**

IMPLEMENTATION DEFINED.

**Accessing the AMAIR\_EL3**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
AMAIR_EL3	11	110	1010	0011	000

**Accessibility**

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

## D7.2.14 CCSIDR\_EL1, Current Cache Size ID Register

The CCSIDR\_EL1 characteristics are:

### Purpose

Provides information about the architecture of the currently selected cache.

### Configurations

AArch64 System register CCSIDR\_EL1 is architecturally mapped to AArch32 System register [CCSIDR](#).

The implementation includes one CCSIDR\_EL1 for each cache that it can access. [CSSELR\\_EL1](#) selects which Cache Size ID Register is accessible.

### Attributes

CCSIDR\_EL1 is a 32-bit register.

## Field descriptions

The CCSIDR\_EL1 bit assignments are:

31	28 27	13 12	3 2 0
UNKNOWN	NumSets	Associativity	LineSize

### UNKNOWN, bits [31:28]

Reserved, UNKNOWN.

### NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

### Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

### LineSize, bits [2:0]

( $\log_2(\text{Number of bytes in cache line})$ ) - 4. For example:

For a line length of 16 bytes:  $\log_2(16) = 4$ , LineSize entry = 0. This is the minimum line length.

For a line length of 32 bytes:  $\log_2(32) = 5$ , LineSize entry = 1.

### Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

## Accessing the CCSIDR\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CCSIDR_EL1	11	001	0000	0000	000

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

If [CSSELR\\_EL1](#).Level is programmed to a cache level that is not implemented, then on a read of the CCSIDR\_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR\_EL1 read is treated as NOP.
- The CCSIDR\_EL1 read is UNDEFINED.
- The CCSIDR\_EL1 read returns an UNKNOWN value.

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2](#).TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2](#).TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

### D7.2.15 CLIDR\_EL1, Cache Level ID Register

The CLIDR\_EL1 characteristics are:

## Purpose

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

## Configurations

AArch64 System register CLIDR\_EL1 is architecturally mapped to AArch32 System register CLIDR.

## Attributes

CLIDR\_EL1 is a 64-bit register.

## Field descriptions

The CLIDR\_EL1 bit assignments are:

**Bits [63:33]**

Reserved, RES0.

**ICB, bits [32:30]**

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The possible values are:

000	Not disclosed by this mechanism.
001	L1 cache is the highest Inner Cacheable level.
010	L2 cache is the highest Inner Cacheable level.
011	L3 cache is the highest Inner Cacheable level.
100	L4 cache is the highest Inner Cacheable level.
101	L5 cache is the highest Inner Cacheable level.
110	L6 cache is the highest Inner Cacheable level.
111	L7 cache is the highest Inner Cacheable level.

**LoUU, bits [29:27]**

Level of Unification Uniprocessor for the cache hierarchy.

**LoC, bits [26:24]**

Level of Coherence for the cache hierarchy.

**LoUIS, bits [23:21]**

Level of Unification Inner Shareable for the cache hierarchy.

### Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 1 to 7

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

000	No cache.
001	Instruction cache only.
010	Data cache only.
011	Separate instruction and data caches.
100	Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

### Accessing the CLIDR\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CLIDR_EL1	11	001	0000	0000	001

### Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

### Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TID2](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2.TID2](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

## D7.2.16 CONTEXTIDR\_EL1, Context ID Register (EL1)

The CONTEXTIDR\_EL1 characteristics are:

### Purpose

Identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

This register is used:

- In ARMv8.0.
- When [ARMv8.1-VHE](#) is implemented and [HCR\\_EL2.E2H](#) is 0.

### Note

When [ARMv8.1-VHE](#) is implemented and [HCR\\_EL2.E2H](#) is set to 1, [CONTEXTIDR\\_EL2](#) is used.

### Configurations

AArch64 System register CONTEXTIDR\_EL1 is architecturally mapped to AArch32 System register [CONTEXTIDR](#).

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

CONTEXTIDR\_EL1 is a 32-bit register.

### Field descriptions

The CONTEXTIDR\_EL1 bit assignments are:

### PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

### Note

In AArch32 state, when [TTBCR.EAE](#) is set to 0, [CONTEXTIDR.ASID](#) holds the ASID.

In AArch64 state, CONTEXTIDR\_EL1 is independent of the ASID, and for the EL1&0 translation regime either [TTBR0\\_EL1](#) or [TTBR1\\_EL1](#) holds the ASID.

### Accessing the CONTEXTIDR\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CONTEXTIDR_EL1	11	000	1101	0000	001
CONTEXTIDR_EL12	11	101	1101	0000	001

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
CONTEXTIDR_EL1	x	x	0	-	RW	n/a	RW
CONTEXTIDR_EL1	0	0	1	-	RW	RW	RW
CONTEXTIDR_EL1	0	1	1	-	n/a	RW	RW
CONTEXTIDR_EL1	1	0	1	-	RW	<a href="#">CONTEXTIDR_EL2</a>	RW
CONTEXTIDR_EL1	1	1	1	-	n/a	<a href="#">CONTEXTIDR_EL2</a>	RW
CONTEXTIDR_EL12	x	x	0	-	-	n/a	-
CONTEXTIDR_EL12	0	0	1	-	-	-	-
CONTEXTIDR_EL12	0	1	1	-	n/a	-	-
CONTEXTIDR_EL12	1	0	1	-	-	RW	RW
CONTEXTIDR_EL12	1	1	1	-	n/a	RW	RW

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic [CONTEXTIDR\\_EL1](#) or [CONTEXTIDR\\_EL12](#) are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

## D7.2.17 CONTEXTIDR\_EL2, Context ID Register (EL2)

The CONTEXTIDR\_EL2 characteristics are:

### Purpose

When [ARMv8.1-VHE](#) is implemented and [HCR\\_EL2.E2H](#) is set to 1, identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

### Note

In ARMv8.0, or when [ARMv8.1-VHE](#) is implemented and [HCR\\_EL2.E2H](#) is 0, [CONTEXTIDR\\_EL1](#) is used.

### Configurations

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

### Attributes

CONTEXTIDR\_EL2 is a 32-bit register.

### Field descriptions

The CONTEXTIDR\_EL2 bit assignments are:

### PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

### Note

In AArch32 state, when [TTBCR.EAE](#) is set to 0, [CONTEXTIDR.ASID](#) holds the ASID.

In AArch64 state, CONTEXTIDR\_EL2 is independent of the ASID, and for the EL2&0 translation regime either [TTBR0\\_EL2](#) or [TTBR1\\_EL2](#) holds the ASID.

### Accessing the CONTEXTIDR\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CONTEXTIDR_EL2	11	100	1101	0000	001
CONTEXTIDR_EL1	11	000	1101	0000	001

### Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
CONTEXTIDR_EL2	x	x	0	-	-	n/a	RW
CONTEXTIDR_EL2	0	0	1	-	-	RW	RW
CONTEXTIDR_EL2	0	1	1	-	n/a	RW	RW
CONTEXTIDR_EL2	1	0	1	-	-	RW	RW
CONTEXTIDR_EL2	1	1	1	-	n/a	RW	RW
CONTEXTIDR_EL1	x	x	0	-	<a href="#">CONTEXTIDR_EL1</a>	n/a	<a href="#">CONTEXTIDR_EL1</a>
CONTEXTIDR_EL1	0	0	1	-	<a href="#">CONTEXTIDR_EL1</a>	<a href="#">CONTEXTIDR_EL1</a>	<a href="#">CONTEXTIDR_EL1</a>
CONTEXTIDR_EL1	0	1	1	-	n/a	<a href="#">CONTEXTIDR_EL1</a>	<a href="#">CONTEXTIDR_EL1</a>
CONTEXTIDR_EL1	1	0	1	-	<a href="#">CONTEXTIDR_EL1</a>	RW	<a href="#">CONTEXTIDR_EL1</a>
CONTEXTIDR_EL1	1	1	1	-	n/a	RW	<a href="#">CONTEXTIDR_EL1</a>

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL2 using the mnemonic [CONTEXTIDR\\_EL2](#) or [CONTEXTIDR\\_EL1](#) are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## D7.2.18 CPACR\_EL1, Architectural Feature Access Control Register

The CPACR\_EL1 characteristics are:

### Purpose

Controls access to trace, SVE, Advanced SIMD and floating-point functionality.

### Configurations

AArch64 System register CPACR\_EL1 is architecturally mapped to AArch32 System register [CPACR](#).

When [HCR\\_EL2](#).{E2H, TGE} == {1, 1}, the fields in this register have no effect on execution at EL0 and EL1. In this case, the controls provided by [CPTR\\_EL2](#) are used.

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

CPACR\_EL1 is a 32-bit register.

### Field descriptions

The CPACR\_EL1 bit assignments are:

### Bits [31:29]

Reserved, RES0.

### TTA, bit [28]

Traps EL0 and EL1 System register accesses to all implemented trace registers to EL1, or to EL2 when [SCR\\_EL3](#).NS is 1 and [HCR\\_EL2](#).TGE is 1, from both Execution states.

0 This control does not cause any instructions to be trapped.

1 This control causes EL0 and EL1 System register accesses to all implemented trace registers to be trapped.

### Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of [CPACR\\_EL1](#).TTA is 1.
- The ARMv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not implemented, this bit is RES0.

### Bits [27:22]

Reserved, RES0.

### FPEN, bits [21:20]

Traps EL0 and EL1 accesses to the SVE, Advanced SIMD, and floating-point registers to EL1, or to EL2 when [SCR\\_EL3.NS](#) is 1 and [HCR\\_EL2.TGE](#) is 1, from both Execution states, unless SVE is implemented and they are trapped by [CPACR\\_EL1.ZEN](#).

- |    |  |
|----|--|
| 00 | This control causes any instructions at EL0 or EL1 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped.   |
| 01 | This control causes any instructions at EL0 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, but does not cause any instruction in EL1 to be trapped. |
| 10 | This control causes any instructions at EL0 or EL1 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped.   |
| 11 | This control does not cause any instructions to be trapped.  |

Writes to [MVFR0](#), [MVFR1](#) and [MVFR2](#) from EL1 or higher are CONSTRAINED UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONSTRAINED UNPREDICTABLE behavior.

#### Note

- Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
- Accesses from EL0 to [FPSID](#), [MVFR0](#), [MVFR1](#), [MVFR2](#), and [FPEXC](#) are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of [CPACR\\_EL1.FPEN](#) is not 11.

### Bits [19:18]

Reserved, RES0.

### ZEN, bits [17:16]

#### *In ARMv8.2*

Traps SVE instructions and instructions that access SVE System registers at EL0 and EL1 to EL1, or to EL2 when [SCR\\_EL3.NS](#) and [HCR\\_EL2.TGE](#) are both 1. Defined values are:

- |    |  |
|----|--|
| 00 | This control causes these instructions executed at EL0 or EL1 to be trapped.   |
| 01 | This control causes these instructions executed at EL0 to be trapped, but does not cause any instruction in EL1 to be trapped. |
| 10 | This control causes these instructions executed at EL0 or EL1 to be trapped.   |
| 11 | This control does not cause any instruction to be trapped.   |

If [SVE](#) is not implemented, this field is RES0.

#### *In ARMv8.1 and ARMv8.0.*

Reserved, RES0.

### Bits [15:0]

Reserved, RES0.

## Accessing the CPACR\_EL1

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CPACR_EL1	11	000	0001	0000	010
CPACR_EL12	11	101	0001	0000	010

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
CPACR_EL1	x	x	0	-	RW	n/a	RW
CPACR_EL1	0	0	1	-	RW	RW	RW
CPACR_EL1	0	1	1	-	n/a	RW	RW
CPACR_EL1	1	0	1	-	RW	<a href="#">CPTR_EL2</a>	RW
CPACR_EL1	1	1	1	-	n/a	<a href="#">CPTR_EL2</a>	RW
CPACR_EL12	x	x	0	-	-	n/a	-
CPACR_EL12	0	0	1	-	-	-	-
CPACR_EL12	0	1	1	-	n/a	-	-
CPACR_EL12	1	0	1	-	-	RW	RW
CPACR_EL12	1	1	1	-	n/a	RW	RW

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic CPACR\_EL1 or CPACR\_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):  
— If [CPTR\\_EL2.TCPAC](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):  
— If [CPTR\\_EL2.TCPAC](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL3 is implemented and is using AArch64:  
— If [CPTR\\_EL3.TCPAC](#)==1, accesses to this register from EL1 and EL2 are trapped to EL3.

## D7.2.19 CPTR\_EL2, Architectural Feature Trap Register (EL2)

The CPTR\_EL2 characteristics are:

### Purpose

Controls:

- Trapping to EL2 of access to [CPACR](#), [CPACR\\_EL1](#), trace functionality, and to SVE, Advanced SIMD and floating-point functionality.
- EL2 access to trace functionality, and to SVE, Advanced SIMD and floating-point functionality.

### Configurations

AArch64 System register CPTR\_EL2 is architecturally mapped to AArch32 System register [HCPTR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

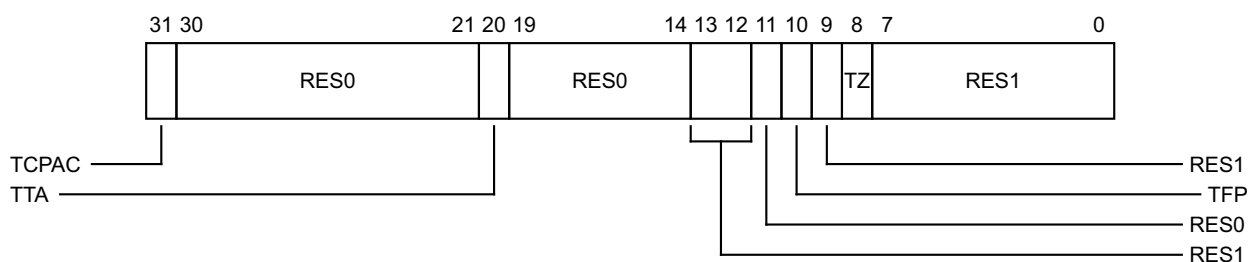

### Attributes

CPTR\_EL2 is a 32-bit register.

### Field descriptions

The CPTR\_EL2 bit assignments are:

**When *HCR\_EL2.E2H* == 0:**

This format applies in all ARMv8.0 implementations.

### TCPAC, bit [31]

Traps Non-secure EL1 accesses to [CPACR\\_EL1](#) or [CPACR](#) to EL2, from both Execution states.

0 This control does not cause any instructions to be trapped.

1 Non-secure EL1 accesses to [CPACR\\_EL1](#) and [CPACR](#) are trapped to EL2.

### Note

[CPACR\\_EL1](#) and [CPACR](#) are not accessible at EL0.

### Bits [30:21]

Reserved, RES0.

### TTA, bit [20]

Traps Non-secure System register accesses to all implemented trace registers to EL2, from both Execution states.

0 This control does not cause any instructions to be trapped.

- 1 Any attempt at EL2, or Non-secure EL0 or EL1, to execute a System register access to an implemented trace register is trapped to EL2, unless it is trapped by [CPACR.NSTRCDIS](#) or [CPACR\\_EL1.TTA](#).

**Note**

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of [CPTR\\_EL2.TTA](#) is 1.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

**Bits [19:14]**

Reserved, RES0.

**Bits [13:12]**

Reserved, RES1.

**Bit [11]**

Reserved, RES0.

**TFP, bit [10]**

Traps Non-secure accesses to SVE, Advanced SIMD and floating-point functionality to EL2, from both Execution states.

- 0 This control does not cause any instructions to be trapped.
- 1 Any attempt at EL2, or Non-secure EL0 or EL1, to execute an instruction that uses the registers associated with SVE, Advanced SIMD and floating-point execution is trapped to EL2, unless it is trapped by [CPACR.cp10](#), [CPACR\\_EL1.FPEN](#), and if SVE is implemented, [CPACR\\_EL1.ZEN](#), or [CPTR\\_EL2.TZ](#).

**Bit [9]**

Reserved, RES1.

**TZ, bit [8]**

**In ARMv8.2**

Present only if [SVE](#) is implemented.

Traps Non-secure execution at EL2, EL1, or EL0 of SVE instructions and instructions that access SVE System registers to EL2. Defined values are:

- 0 This control does not cause any instruction to be trapped.
- 1 This control causes these instructions to be trapped, unless [HCR\\_EL2.TGE](#) is 0 and they are trapped by [CPACR\\_EL1](#).

If [SVE](#) is not implemented, this field is RES1.

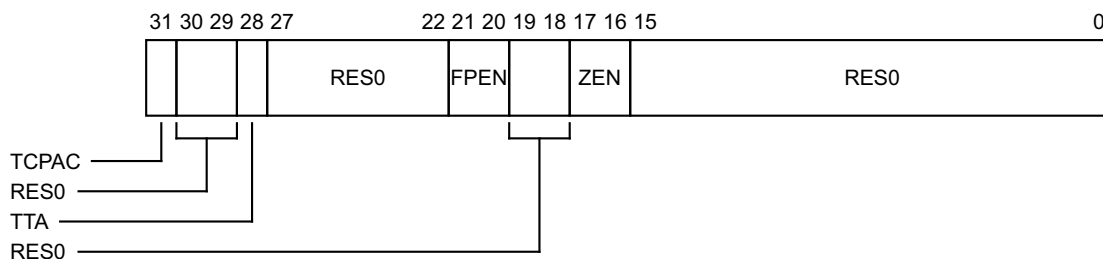

**In ARMv8.1 and ARMv8.0.**

Reserved, RES1.

**Bits [7:0]**

Reserved, RES1.

**When  $HCR\_EL2.E2H == 1$ :**

#### TCPAC, bit [31]

When  $HCR\_EL2.TGE$  is 0, traps Non-secure EL1 accesses to [CPACR\\_EL1](#) and [CPACR](#) to EL2, from both Execution states.

0 This control does not cause any instructions to be trapped.

1 Non-secure EL1 accesses to [CPACR\\_EL1](#) and [CPACR](#) are trapped to EL2.

When  $HCR\_EL2.TGE$  is 1, this control does not cause any instructions to be trapped.

#### ———— Note ————

[CPACR\\_EL1](#) and [CPACR](#) are not accessible at EL0.

#### Bits [30:29]

Reserved, RES0.

#### TTA, bit [28]

Traps Non-secure System register accesses to all implemented trace registers to EL2, from both Execution states.

0 This control does not cause any instructions to be trapped.

1 Any attempt at EL2, or Non-secure EL0 or EL1, to execute a System register access to an implemented trace register is trapped to EL2, unless  $HCR\_EL2.TGE$  is 0 and it is trapped by [CPACR.NSTRCDIS](#) or [CPACR\\_EL1.TTA](#).

When  $HCR\_EL2.TGE$  is 1, any attempt at EL2, or Non-secure EL0, to execute a System register access to an implemented trace register is trapped to EL2.

#### ———— Note ————

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of [CPTR\\_EL2.TTA](#) is 1.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

#### Bits [27:22]

Reserved, RES0.

## FPEN, bits [21:20]

Traps EL2, Non-secure EL0 and, when [HCR\\_EL2.TGE](#) is 0, Non-secure EL1 accesses to the SVE, Advanced SIMD and floating-point registers to EL2, from both Execution states.

- |    |   |
|----|---|
| 00 | This control causes any instructions at Non-secure EL0, EL1, or EL2 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, unless <a href="#">HCR_EL2.TGE</a> is 0 and they are trapped by <a href="#">CPACR.cp10</a> , <a href="#">CPACR_EL1.FPEN</a> , <a href="#">CPACR_EL1.ZEN</a> , or <a href="#">CPTR_EL2.ZEN</a> . |
| 01 | When <a href="#">HCR_EL2.TGE</a> is 0, this control does not cause any instructions to be trapped. When <a href="#">HCR_EL2.TGE</a> is 1, this control causes instructions at Non-secure EL0 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, unless they are trapped by <a href="#">CPTR_EL2.ZEN</a> .              |
| 10 | This control causes any instructions at Non-secure EL0, EL1, or EL2 that use the registers associated with SVE, Advanced SIMD and floating-point execution to be trapped, unless <a href="#">HCR_EL2.TGE</a> is 0 and they are trapped by <a href="#">CPACR.cp10</a> , <a href="#">CPACR_EL1.FPEN</a> , <a href="#">CPACR_EL1.ZEN</a> , or <a href="#">CPTR_EL2.ZEN</a> . |
| 11 | This control does not cause any instructions to be trapped.   |

Writes to [MVFR0](#), [MVFR1](#), and [MVFR2](#) from EL1 or higher are CONstrained UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONstrained UNPREDICTABLE behavior.

### ———— Note ————

- Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
- Accesses from EL0 to [FPSID](#), [MVFR0](#), [MVFR1](#), [MVFR2](#), and [FPEXC](#) are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of [CPTR\\_EL2.FPEN](#) is not 11.

## Bits [19:18]

Reserved, RES0.

## ZEN, bits [17:16]

### *In ARMv8.2*

Present only if [SVE](#) is implemented.

Traps Non-secure execution at EL2, EL1, and EL0 of SVE instructions or instructions that access SVE System registers to EL2.

Defined values are:

- |    |  |
|----|--|
| 00 | This control causes Non-secure execution at EL2, EL1, and EL0 of these instructions to be trapped, unless <a href="#">HCR_EL2.TGE</a> is 0 and they are trapped by <a href="#">CPACR_EL1</a> .   |
| 01 | When <a href="#">HCR_EL2.TGE</a> is 0, this control does not cause any instruction to be trapped. When <a href="#">HCR_EL2.TGE</a> is 1, this control causes these instructions executed at Non-secure EL0 to be trapped, but does not cause any instruction at EL2 to be trapped. |
| 10 | This control causes Non-secure execution at EL2, EL1, and EL0 of these instructions to be trapped, unless <a href="#">HCR_EL2.TGE</a> is 0 and they are trapped by <a href="#">CPACR_EL1</a> .   |
| 11 | This control does not cause any instruction to be trapped.   |

If [SVE](#) is not implemented, this field is RES0.

### *In ARMv8.1.*

Reserved, RES0.

## Bits [15:0]

Reserved, RES0.

## Accessing the CPTR\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CPTR_EL2	11	100	0001	0001	010
CPACR_EL1	11	000	0001	0000	010

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
CPTR_EL2	x	x	0	-	-	n/a	RW
CPTR_EL2	0	0	1	-	-	RW	RW
CPTR_EL2	0	1	1	-	n/a	RW	RW
CPTR_EL2	1	0	1	-	-	RW	RW
CPTR_EL2	1	1	1	-	n/a	RW	RW
CPACR_EL1	x	x	0	-	<a href="#">CPACR_EL1</a>	n/a	<a href="#">CPACR_EL1</a>
CPACR_EL1	0	0	1	-	<a href="#">CPACR_EL1</a>	<a href="#">CPACR_EL1</a>	<a href="#">CPACR_EL1</a>
CPACR_EL1	0	1	1	-	n/a	<a href="#">CPACR_EL1</a>	<a href="#">CPACR_EL1</a>
CPACR_EL1	1	0	1	-	<a href="#">CPACR_EL1</a>	RW	<a href="#">CPACR_EL1</a>
CPACR_EL1	1	1	1	-	n/a	RW	<a href="#">CPACR_EL1</a>

This table applies to all instructions that can access this register.

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL3 is implemented and is using AArch64:
  - If [CPTR\\_EL3.TCPAC](#)==1, accesses to this register from EL2 are trapped to EL3.

## D7.2.20 CPTR\_EL3, Architectural Feature Trap Register (EL3)

The CPTR\_EL3 characteristics are:

### Purpose

Controls trapping to EL3 of access to [CPACR\\_EL1](#), [CPTR\\_EL2](#), trace functionality and registers associated with SVE, Advanced SIMD and floating-point execution. Also controls EL3 access to trace functionality and registers associated with SVE, Advanced SIMD and floating-point execution.

### Configurations

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

CPTR\_EL3 is a 32-bit register.

### Field descriptions

The CPTR\_EL3 bit assignments are:

#### TCPAC, bit [31]

Traps all of the following to EL3, from both Security states and both Execution states.

- EL2 accesses to the [CPTR\\_EL2](#) or [HCPTR](#).
- EL2 and EL1 accesses to the [CPACR\\_EL1](#) or [CPACR](#).

When CPTR\_EL3.TCPAC is:

- 0 This control does not cause any instructions to be trapped.
- 1 EL2 accesses to the [CPTR\\_EL2](#) or [HCPTR](#), and EL2 and EL1 accesses to the [CPACR\\_EL1](#) or [CPACR](#), are trapped to EL3, unless they are trapped by [CPTR\\_EL2](#).TCPAC.

#### Bits [30:21]

Reserved, RES0.

#### TTA, bit [20]

Traps System register accesses to the trace registers, from all Exception levels, both Security states, and both Execution states, to EL3.

- 0 This control does not cause any instructions to be trapped.
- 1 Any System register access to the trace registers is trapped to EL3, subject to the exception prioritization rules, unless it is trapped by [CPACR](#).NSTRCDIS, [CPACR\\_EL1](#).TTA or [CPTR\\_EL2](#).TTA.

If System register access to trace functionality is not supported, this bit is RES0.

#### Bits [19:11]

Reserved, RES0.

### TFP, bit [10]

Traps all accesses to SVE, Advanced SIMD and floating-point functionality, from all Exception levels, both Security states, and both Execution states, to EL3.

- 0 This control does not cause any instructions to be trapped.
- 1 Any attempt at any Exception level to execute an instruction that uses the registers associated with SVE, Advanced SIMD and floating-point is trapped to EL3, subject to the exception prioritization rules, unless it is trapped by CPACR.cp10, CPACR\_EL1.FPEN, CPTR\_EL2.TFP, and if SVE is implemented, CPACR\_EL1.ZEN, CPTR\_EL2.FPEN, CPTR\_EL2.ZEN, or CPTR\_EL2.TZ.

### Bit [9]

Reserved, RES0.

### EZ, bit [8]

#### *In ARMv8.2*

Present only if SVE is implemented.

Traps all accesses to SVE functionality and registers from all Exception levels, and both Security states, to EL3. Defined values are:

- 0 This control causes these instructions executed at any Exception level to be trapped, unless they are trapped by CPTR\_EL2 or CPACR\_EL1.
- 1 This control does not cause any instruction to be trapped.

If SVE is not implemented, this field is RES0.

#### *In ARMv8.1 and ARMv8.0.*

Reserved, RES0.

### Bits [7:0]

Reserved, RES0.

## Accessing the CPTR\_EL3

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CPTR_EL3	11	110	0001	0001	010

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

## D7.2.21 CSSELR\_EL1, Cache Size Selection Register

The CSSELR\_EL1 characteristics are:

### Purpose

Selects the current Cache Size ID Register, [CCSIDR\\_EL1](#), by specifying the required cache level and the cache type (either instruction or data cache).

### Configurations

AArch64 System register CSSELR\_EL1 is architecturally mapped to AArch32 System register [CSSELR](#).

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

CSSELR\_EL1 is a 32-bit register.

### Field descriptions

The CSSELR\_EL1 bit assignments are:

#### Bits [31:4]

Reserved, RES0.

#### Level, bits [3:1]

Cache level of required cache. Permitted values are:

000	Level 1 cache
001	Level 2 cache
010	Level 3 cache
011	Level 4 cache
100	Level 5 cache
101	Level 6 cache
110	Level 7 cache

All other values are reserved.

If CSSELR\_EL1.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

#### InD, bit [0]

Instruction not Data bit. Permitted values are:

0	Data or unified cache.
1	Instruction cache.

If CSSELR\_EL1.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

### Accessing the CSSELR\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CSSELR_EL1	11	010	0000	0000	000

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TID2](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2.TID2](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.

## D7.2.22 CTR\_EL0, Cache Type Register

The CTR\_EL0 characteristics are:

### Purpose

Provides information about the architecture of the caches.

### Configurations

AArch64 System register CTR\_EL0 is architecturally mapped to AArch32 System register [CTR](#).

### Attributes

CTR\_EL0 is a 32-bit register.

### Field descriptions

The CTR\_EL0 bit assignments are:

#### Bit [31]

Reserved, RES1.

#### Bits [30:28]

Reserved, RES0.

#### CWG, bits [27:24]

Cache writeback granule.  $\log_2$  of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of `0b0000` indicates that this register does not provide Cache writeback granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than `0b1001` are reserved.

ARM recommends that an implementation that does not support cache write-back implements this field as `0b0001`. This applies, for example, to an implementation that supports only write-through caches.

#### ERG, bits [23:20]

Exclusives reservation granule.  $\log_2$  of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of `0b0000` indicates that this register does not provide Exclusives reservation granule information and the architectural maximum of 512 words (2KB) must be assumed.

Values greater than `0b1001` are reserved.

#### DminLine, bits [19:16]

$\log_2$  of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

### L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

00	VMID aware Physical Index, Physical tag (VPIPT)
01	ASID-tagged Virtual Index, Virtual Tag (AIVIVT)
10	Virtual Index, Physical Tag (VIPT)
11	Physical Index, Physical Tag (PIPT)

The value 0b01 is reserved in ARMv8.

### Bits [13:4]

Reserved, RES0.

### IminLine, bits [3:0]

Log<sub>2</sub> of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

## Accessing the CTR\_EL0

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CTR_EL0	11	011	0000	0000	001

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If [SCTLR\\_EL1.UCT](#)==0, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TID2](#)==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and  $(SCR\_EL3.NS == 1) \ \&\& \ (HCR\_EL2.E2H == 1) \ \&\& \ (HCR\_EL2.TGE == 0)$ :
  - If [HCR\\_EL2.TID2](#)==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

## D7.2.23 DACR32\_EL2, Domain Access Control Register

The DACR32\_EL2 characteristics are:

### Purpose

Allows access to the AArch32 [DACR](#) register from AArch64 state only. Its value has no effect on execution in AArch64 state.

### Configurations

AArch64 System register DACR32\_EL2 is architecturally mapped to AArch32 System register [DACR](#).

If EL1 does not support AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

DACR32\_EL2 is a 32-bit register.

### Field descriptions

The DACR32\_EL2 bit assignments are:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0																

### D<n>, bits [2n+1:2n], for n = 0 to 15

Domain n access permission, where n = 0 to 15. Permitted values are:

- 00 No access. Any access to the domain generates a Domain fault.
  - 01 Client. Accesses are checked against the permission bits in the translation tables.
  - 11 Manager. Accesses are not checked against the permission bits in the translation tables.
- The value 10 is reserved.

### Accessing the DACR32\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
DACR32_EL2	11	100	0011	0000	000

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

## D7.2.24 DCZID\_EL0, Data Cache Zero ID register

The DCZID\_EL0 characteristics are:

### Purpose

Indicates the block size that is written with byte values of 0 by the [DC ZVA](#) (Data Cache Zero by Address) system instruction.

### Configurations

There are no configuration notes.

### Attributes

DCZID\_EL0 is a 32-bit register.

### Field descriptions

The DCZID\_EL0 bit assignments are:

### Bits [31:5]

Reserved, RES0.

### DZP, bit [4]

Data Zero prohibited. Permitted values are:

0 [DC ZVA](#) instruction is permitted.

1 [DC ZVA](#) instruction is prohibited.

The value read from this field is governed by the access state and the values of the [HCR\\_EL2.TDZ](#) and [SCTLR\\_EL1.DZE](#) bits.

### BS, bits [3:0]

$\log_2$  of the block size in words. The maximum size supported is 2KB (value == 9).

### Accessing the DCZID\_EL0

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
DCZID_EL0	11	011	0000	0000	111

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

## D7.2.25 ESR\_EL1, Exception Syndrome Register (EL1)

The ESR\_EL1 characteristics are:

### Purpose

Holds syndrome information for an exception taken to EL1.

### Configurations

AArch64 System register ESR\_EL1 is architecturally mapped to AArch32 System register [DFSR](#).

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

ESR\_EL1 is a 32-bit register.

### Field descriptions

See [ESR\\_ELx](#).

### Accessing the ESR\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
ESR_EL1	11	000	0101	0010	000
ESR_EL12	11	101	0101	0010	000

### Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
ESR_EL1	x	x	0	-	RW	n/a	RW
ESR_EL1	0	0	1	-	RW	RW	RW
ESR_EL1	0	1	1	-	n/a	RW	RW
ESR_EL1	1	0	1	-	RW	<a href="#">ESR_EL2</a>	RW
ESR_EL1	1	1	1	-	n/a	<a href="#">ESR_EL2</a>	RW
ESR_EL12	x	x	0	-	-	n/a	-
ESR_EL12	0	0	1	-	-	-	-

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
ESR_EL12	0	1	1	-	n/a	-	-
ESR_EL12	1	0	1	-	-	RW	RW
ESR_EL12	1	1	1	-	n/a	RW	RW

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic ESR\_EL1 or ESR\_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

### Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

## D7.2.26 ESR\_EL2, Exception Syndrome Register (EL2)

The ESR\_EL2 characteristics are:

### Purpose

Holds syndrome information for an exception taken to EL2.

### Configurations

AArch64 System register ESR\_EL2 is architecturally mapped to AArch32 System register [HSR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

ESR\_EL2 is a 32-bit register.

### Field descriptions

See [ESR\\_ELx](#).

### Accessing the ESR\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
ESR_EL2	11	100	0101	0010	000
ESR_EL1	11	000	0101	0010	000

### Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
ESR_EL2	x	x	0	-	-	n/a	RW
ESR_EL2	0	0	1	-	-	RW	RW
ESR_EL2	0	1	1	-	n/a	RW	RW
ESR_EL2	1	0	1	-	-	RW	RW
ESR_EL2	1	1	1	-	n/a	RW	RW
ESR_EL1	x	x	0	-	<a href="#">ESR_EL1</a>	n/a	<a href="#">ESR_EL1</a>
ESR_EL1	0	0	1	-	<a href="#">ESR_EL1</a>	<a href="#">ESR_EL1</a>	<a href="#">ESR_EL1</a>

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
ESR_EL1	0	1	1	-	n/a	ESR_EL1	ESR_EL1
ESR_EL1	1	0	1	-	ESR_EL1	RW	ESR_EL1
ESR_EL1	1	1	1	-	n/a	RW	ESR_EL1

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL2 using the mnemonic ESR\_EL2 or ESR\_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## D7.2.27 ESR\_EL3, Exception Syndrome Register (EL3)

The ESR\_EL3 characteristics are:

### Purpose

Holds syndrome information for an exception taken to EL3.

### Configurations

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

ESR\_EL3 is a 32-bit register.

## Field descriptions

See [ESR\\_ELx](#).

## Accessing the ESR\_EL3

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
ESR_EL3	11	110	0101	0010	000

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
0	0	1	-	-	-	RW
0	1	1	-	n/a	-	RW
1	0	1	-	-	-	RW
1	1	1	-	n/a	-	RW

## D7.2.28 ESR\_ELx, Exception Syndrome Register (ELx)

This page describes [ESR\\_EL1](#), [ESR\\_EL2](#), and [ESR\\_EL3](#).

The ESR\_ELx characteristics are:

### Purpose

Holds syndrome information for an exception taken to ELx.

### Configurations

If EL2 is not implemented, [ESR\\_EL2](#) is RES0 from EL3.

### Attributes

The ESR\_ELx registers are 32-bit registers.

### Field descriptions

The ESR\_ELx bit assignments are:

31	26	25	24	0
EC	IL	ISS		

ESR\_ELx is made UNKNOWN as a result of an exception return from ELx.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to ELx, the value of ESR\_ELx is UNKNOWN. The value written to ESR\_ELx must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

### EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

**EC == 000000**

Unknown reason.

This value is valid for all described registers.

See [ISS encoding for exceptions with an unknown reason](#).

**EC == 000001**

Trapped WFI or WFE instruction execution.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

This value is valid for all described registers.

See [ISS encoding for an exception from a WFI or WFE instruction](#).

**EC == 000011**

Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.

This value is valid for all described registers.

See [ISS encoding for an exception from an MCR or MRC access](#).

**EC == 000100**

Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.

This value is valid for all described registers.

See [ISS encoding for an exception from an MCRR or MRRC access](#).

**EC == 000101**

Trapped MCR or MRC access with (coproc==1110).

This value is valid for all described registers.

See [ISS encoding for an exception from an MCR or MRC access](#).

**EC == 000110**

Trapped LDC or STC access.

The only architected uses of these instructions are:

- An STC to write data to memory from [DBGDTRRXint](#).
- An LDC to read data from memory to [DBGDTRTXint](#).

This value is valid for all described registers.

See [ISS encoding for an exception from an LDC or STC instruction](#).

**EC == 000111**

Access to SVE, Advanced SIMD, or floating-point functionality trapped by [CPACR\\_EL1.FPEN](#), [CPTR\\_EL2.FPEN](#), [CPTR\\_EL2.TFP](#), or [CPTR\\_EL3.TFP](#) control. Excludes exceptions resulting from [CPACR\\_EL1](#) when the value of [HCR\\_EL2.TGE](#) is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in [The EC used to report an exception routed to EL2 because HCR\\_EL2.TGE is 1](#) on page D1-1813.

This value is valid for all described registers.

See [ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR\\_EL1.FPEN or CPTR\\_ELx.TFP](#).

**EC == 001000**

Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

This value is valid for [ESR\\_EL2](#).

See [ISS encoding for an exception from an MCR or MRC access](#).

**EC == 001100**

Trapped MRRC access with (coproc==1110).

This value is valid for all described registers.

See [ISS encoding for an exception from an MCRR or MRRC access](#).

**EC == 001110**

Illegal Execution state.

This value is valid for all described registers.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

**EC == 010001**

SVC instruction execution in AArch32 state.

This is reported in [ESR\\_EL2](#) only when the exception is generated because the value of [HCR\\_EL2.TGE](#) is 1.

This value is valid for [ESR\\_EL1](#) and [ESR\\_EL2](#).

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

**EC == 010010**

HVC instruction execution in AArch32 state, when HVC is not disabled.

This value is valid for [ESR\\_EL2](#).

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

**EC == 010011**

SMC instruction execution in AArch32 state, when SMC is not disabled.

This is reported in ESR\_EL2 only when the exception is generated because the value of [HCR\\_EL2.TSC](#) is 1.

This value is valid for [ESR\\_EL2](#) and [ESR\\_EL3](#).

See [ISS encoding for an exception from SMC instruction execution in AArch32 state](#).

**EC == 010101**

SVC instruction execution in AArch64 state.

This value is valid for all described registers.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

**EC == 010110**

HVC instruction execution in AArch64 state, when HVC is not disabled.

This value is valid for [ESR\\_EL2](#) and [ESR\\_EL3](#).

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

**EC == 010111**

SMC instruction execution in AArch64 state, when SMC is not disabled.

This is reported in ESR\_EL2 only when the exception is generated because the value of [HCR\\_EL2.TSC](#) is 1.

This value is valid for [ESR\\_EL2](#) and [ESR\\_EL3](#).

See [ISS encoding for an exception from SMC instruction execution in AArch64 state](#).

**EC == 011000**

Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC 0b000000, 0b000001 or 0b000111.

This include all instructions that cause exceptions that are part of the encoding space defined in [System instruction class encoding overview on page C5-313](#), except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.

This value is valid for all described registers.

See [ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state](#).

**EC == 011001**

Access to SVE functionality as a result of [CPACR\\_EL1.ZEN](#), [CPTR\\_EL2.ZEN](#), [CPTR\\_EL2.TZ](#), or [CPTR\\_EL3.EZ](#), except those reported using EC value 0b000000.

This EC is defined only if [SVE](#) is implemented.

This value is valid for all described registers.

See [ISS encoding for an exception from an access to SVE functionality, resulting from CPACR\\_EL1.ZEN, CPTR\\_EL2.ZEN, CPTR\\_EL2.TZ, or CPTR\\_EL3.EZ..](#)

**EC == 011111**

IMPLEMENTATION DEFINED exception to EL3.

This value is valid for [ESR\\_EL3](#).

See [ISS encoding for a IMPLEMENTATION DEFINED exception to EL3](#).

**EC == 100000**

Instruction Abort from a lower Exception level.

Used for MMU faults generated by instruction accesses and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

This value is valid for all described registers.

See [ISS encoding for an exception from an Instruction Abort](#).

**EC == 100001**

Instruction Abort taken without a change in Exception level.

Used for MMU faults generated by instruction accesses and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

This value is valid for all described registers.

See [ISS encoding for an exception from an Instruction Abort](#).

**EC == 100010**

PC alignment fault exception.

This value is valid for all described registers.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

**EC == 100100**

Data Abort from a lower Exception level.

Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

This value is valid for all described registers.

See [ISS encoding for an exception from a Data Abort](#).

**EC == 100101**

Data Abort taken without a change in Exception level.

Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

This value is valid for all described registers.

See [ISS encoding for an exception from a Data Abort](#).

**EC == 100110**

SP alignment fault exception.

This value is valid for all described registers.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

**EC == 101000**

Trapped floating-point exception taken from AArch32 state.

Whether this Exception class is supported is IMPLEMENTATION DEFINED.

This value is valid for [ESR\\_EL1](#) and [ESR\\_EL2](#).

See [ISS encoding for an exception from a trapped floating-point exception](#).

**EC == 101100**

Trapped floating-point exception taken from AArch64 state.

Whether this Exception class is supported is IMPLEMENTATION DEFINED.

This value is valid for all described registers.

See [ISS encoding for an exception from a trapped floating-point exception](#).

**EC == 101111**

SError interrupt.

This value is valid for all described registers.

See [ISS encoding for an SError interrupt](#).

**EC == 110000**

Breakpoint exception from a lower Exception level.

This value is valid for [ESR\\_EL1](#) and [ESR\\_EL2](#).

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#).

**EC == 110001**

Breakpoint exception taken without a change in Exception level.

This value is valid for [ESR\\_EL1](#) and [ESR\\_EL2](#).

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#).

**EC == 110010**

Software Step exception from a lower Exception level.

This value is valid for [ESR\\_EL1](#) and [ESR\\_EL2](#).

See [ISS encoding for an exception from a Software Step exception](#).

**EC == 110011**

Software Step exception taken without a change in Exception level.

This value is valid for [ESR\\_EL1](#) and [ESR\\_EL2](#).

See [ISS encoding for an exception from a Software Step exception](#).

**EC == 110100**

Watchpoint exception from a lower Exception level.

This value is valid for [ESR\\_EL1](#) and [ESR\\_EL2](#).

See [ISS encoding for an exception from a Watchpoint exception](#).

**EC == 110101**

Watchpoint exception taken without a change in Exception level.

This value is valid for [ESR\\_EL1](#) and [ESR\\_EL2](#).

See [ISS encoding for an exception from a Watchpoint exception](#).

**EC == 111000**

BKPT instruction execution in AArch32 state.

This value is valid for [ESR\\_EL1](#) and [ESR\\_EL2](#).

See [ISS encoding for an exception from execution of a Breakpoint instruction](#).

**EC == 111010**

Vector Catch exception from AArch32 state.

The only case where a Vector Catch exception is taken to an Exception level that is using AArch64 is when the exception is routed to EL2 and EL2 is using AArch64.

This value is valid for [ESR\\_EL2](#).

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#).

**EC == 111100**

BRK instruction execution in AArch64 state.

This is reported in [ESR\\_EL3](#) only if a BRK instruction is executed at EL3.

This value is valid for all described registers.

See [ISS encoding for an exception from execution of a Breakpoint instruction](#).

All other EC values are reserved by ARM, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-6117.

**IL, bit [25]**

Instruction Length for synchronous exceptions. Possible values of this bit are:

- |   |  |
|---|--|
| 0 | 16-bit instruction trapped.  |
| 1 | 32-bit instruction trapped. This value is also used when the exception is one of the following: <ul style="list-style-type: none"> <li>• An SError interrupt.</li> <li>• An Instruction Abort exception.</li> <li>• A PC alignment fault exception.</li> </ul> |

- An SP alignment fault exception.
- A Data Abort exception for which the value of the ISV bit is 0.
- An Illegal Execution state exception.
- Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
 

0	16-bit T32 BKPT instruction.
1	32-bit A32 BKPT instruction or A64 BRK instruction.
- An exception reported using EC value 0b000000.

#### ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number. For an exception taken from AArch32 state, [Mapping of the general-purpose registers between the Execution states on page D1-1888](#) defines this view of the specified AArch32 register. If the AArch32 register descriptor is 0b1111, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  - The value 0b11111.

When the EC field is 0b000000, indicating an exception with an unknown reason, the ISS field is not valid, RES0.

The following subsections describe each ISS format.

#### ISS encoding for exceptions with an unknown reason

This encoding is used by:

- Unknown reason.

The ISS encoding for these exceptions is:

#### Bits [24:0]

Reserved, RES0.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.

- Instruction encodings for instructions not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the [SCTLR\\_EL1](#).{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by [HCR\\_EL2](#).HCD or [SCR\\_EL3](#).HCE.
  - An SMC instruction when disabled by [SCR\\_EL3](#).SMD.
  - An HLT instruction when disabled by [EDSCR](#).HDE.
- Attempted execution of an MSR or MRS instruction to access [SP\\_EL0](#) when the value of [SPSel.SP](#) is 0.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction in Non-secure state from EL0 when the value of [HCR\\_EL2](#).TGE is 1.
  - A DCPS2 instruction from EL1 or EL0 when the value of [SCR\\_EL3](#).NS is 0, or when EL2 is not implemented.
  - A DCPS3 instruction when the value of [EDSCR](#).SDD is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13\_mon. See [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1870](#).
- In Debug state when the value of [EDSCR](#).SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (Banked register) or an MSR (Banked register) instruction to [SPSR\\_mon](#), [SP\\_mon](#), or [LR\\_mon](#).
- An exception that is taken to EL2 because the value of [HCR\\_EL2](#).TGE is 1 that, if the value of [HCR\\_EL2](#).TGE was 0 would have been reported with an [ESR\\_ELx.EC](#) value of 0b000111.
- In an implementation that does not include SVE, execution of an SVE instruction or an instruction which accesses the [ID\\_AA64ZFR0\\_EL1](#), [ZCR\\_EL1](#), [ZCR\\_EL2](#), and [ZCR\\_EL3](#) registers.

### **ISS encoding for an exception from a WFI or WFE instruction**

This encoding is used by:

- Trapped WFI or WFE instruction execution.  
Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

The ISS encoding for these exceptions is:

#### CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

#### COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

#### Bits [19:1]

Reserved, RES0.

#### TI, bit [0]

Trapped instruction. Possible values of this bit are:

- 0 WFI trapped.
- 1 WFE trapped.

The following sections describe configuration settings for generating this exception:

- [Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1845.](#)

- [Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1861.](#)
- [Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1871.](#)

### ISS encoding for an exception from an MCR or MRC access

This encoding is used by:

- Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.
- Trapped MCR or MRC access with (coproc==1110).
- Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

The ISS encoding for these exceptions is:

### CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

### COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

#### Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

#### Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

#### CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

#### Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states on page D1-1888](#).

#### CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value 0b0000.

#### Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- |   |   |
|---|---|
| 0 | Write to System register space. MCR instruction.          |
| 1 | Read from System register space. MRC or VMRS instruction. |

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- [Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1849.](#)
- [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1850.](#)
- [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1853.](#)
- [Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions on page D1-1854.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1855.](#)
- [Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1856.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1857.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1858.](#)
- [Trapping to EL2 of Non-secure EL1 accesses to the CPACR\\_EL1 or CPACR on page D1-1862.](#)
- [General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1864.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1867.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1868.](#)
- [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1870.](#)

- [Trapping to EL3 of EL2 accesses to the CPTR\\_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR\\_EL1 or CPACR on page D1-1873.](#)
- [Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1877.](#)

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000101:

- [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1847.](#)
- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1848.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1858](#), for trapped accesses to the JIDR.
- [Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1863.](#)
- [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1865.](#)
- [Trapping System register accesses to powerdown debug registers to EL2 on page D1-1866.](#)
- [Trapping general System register accesses to debug registers to EL2 on page D1-1866.](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1874.](#)
- [Trapping System register accesses to powerdown debug registers to EL3 on page D1-1875.](#)
- [Trapping general System register accesses to debug registers to EL3 on page D1-1876.](#)

[Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1858](#) describes configuration settings for generating exceptions that are reported using EC value 0b001000.

### ISS encoding for an exception from an MCRR or MRRC access

This encoding is used by:

- Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.
- Trapped MRRC access with (coproc==1110).

The ISS encoding for these exceptions is:

### CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

### COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

### Opc1, bits [19:16]

The Opc1 value from the issued instruction.

### Bit [15]

Reserved, RES0.

### Rt2, bits [14:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states](#) on page D1-1888.

### Rt, bits [9:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states](#) on page D1-1888.

### CRm, bits [4:1]

The CRm value from the issued instruction.

### Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- |   |  |
|---|--|
| 0 | Write to System register space. MCRR instruction.  |
| 1 | Read from System register space. MRRC instruction. |

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000100:

- [Traps to EL1 of EL0 accesses to the Generic Timer registers](#) on page D1-1849.
- [Traps to EL1 of EL0 accesses to Performance Monitors registers](#) on page D1-1850.
- [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers](#) on page D1-1853.

- [General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1864.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1867.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1868.](#)
- [Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1877.](#)

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1847.](#)
- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1848.](#)
- [Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1863.](#)
- [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1865.](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1874.](#)
- [Trapping System register accesses to powerdown debug registers to EL2 on page D1-1866.](#)

### ISS encoding for an exception from an LDC or STC instruction

This encoding is used by:

- Trapped LDC or STC access.  
The only architected uses of these instructions are:
  - An STC to write data to memory from [DBGDTRRXint](#).
  - An LDC to read data from memory to [DBGDTRTXint](#).

The ISS encoding for these exceptions is:

#### CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

#### COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

#### imm8, bits [19:12]

The immediate value from the issued instruction.

#### Bits [11:10]

Reserved, RES0.

#### Rn, bits [9:5]

The Rn value from the issued instruction, the general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states on page D1-1888](#).

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

#### Offset, bit [4]

Indicates whether the offset is added or subtracted:

- |   |                  |
|---|------------------|
| 0 | Subtract offset. |
| 1 | Add offset.      |

This bit corresponds to the U bit in the instruction encoding.

#### AM, bits [3:1]

Addressing mode. The permitted values of this field are:

- |     |   |
|-----|---|
| 000 | Immediate unindexed.  |
| 001 | Immediate post-indexed.   |
| 010 | Immediate offset.   |
| 011 | Immediate pre-indexed.  |
| 100 | Literal unindexed.  |
|     | LDC instruction in A32 instruction set only.  |
|     | For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved. |
| 110 | Literal offset.   |
|     | LDC instruction only.   |

For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-6133.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

#### Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to memory. STC instruction.
- 1 Read from memory. LDC instruction.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000110:

- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers](#) on page D1-1848.
- [Trapping general System register accesses to debug registers to EL2](#) on page D1-1866.
- [Trapping general System register accesses to debug registers to EL3](#) on page D1-1876.

#### ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR\_EL1.FPEN or CPTR\_ELx.TFP

This encoding is used by:

- Access to SVE, Advanced SIMD, or floating-point functionality trapped by CPACR\_EL1.FPEN, CPTR\_EL2.FPEN, CPTR\_EL2.TFP, or CPTR\_EL3.TFP control.  
Excludes exceptions resulting from CPACR\_EL1 when the value of HCR\_EL2.TGE is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in [The EC used to report an exception routed to EL2 because HCR\\_EL2.TGE is 1](#) on page D1-1813.

The ISS encoding for these exceptions is:

The accesses covered by this trap include:

- Execution of SVE or Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include SVE, floating-point or Advanced SIMD, the exception is reported using the EC value 0b000000.

#### CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

#### COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

#### Bits [19:0]

Reserved, RES0.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:

- [Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality on page D1-1848.](#)
- [General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers on page D1-1863.](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1874.](#)

#### ISS encoding for an exception from an access to SVE functionality, resulting from CPACR\_EL1.ZEN, CPTR\_EL2.ZEN, CPTR\_EL2.TZ, or CPTR\_EL3.EZ.

This encoding is used by:

- Access to SVE functionality as a result of CPACR\_EL1.ZEN, CPTR\_EL2.ZEN, CPTR\_EL2.TZ, or CPTR\_EL3.EZ, except those reported using EC value 0b000000.

This EC is defined only if SVE is implemented.

The ISS encoding for these exceptions is:

#### Bits [24:0]

Reserved, RES0.

The accesses covered by this trap include:

- Execution of SVE instructions.
- Accesses to the SVE system registers.

When an implementation does not include SVE, the exception is reported using the EC value 0b000000.

### **ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault**

This encoding is used by:

- Illegal Execution state.
- PC alignment fault exception.
- SP alignment fault exception.

The ISS encoding for these exceptions is:

#### **Bits [24:0]**

Reserved, RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. [SP alignment checking on page D1-1793](#) describes the configuration settings for generating SP alignment fault exceptions.

### **ISS encoding for an exception from HVC or SVC instruction execution**

This encoding is used by:

- SVC instruction execution in AArch32 state.  
This is reported in ESR\_EL2 only when the exception is generated because the value of [HCR\\_EL2.TGE](#) is 1.
- HVC instruction execution in AArch32 state, when HVC is not disabled.
- SVC instruction execution in AArch64 state.
- HVC instruction execution in AArch64 state, when HVC is not disabled.

The ISS encoding for these exceptions is:

#### **Bits [24:16]**

Reserved, RES0.

#### **imm16, bits [15:0]**

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see [SVC](#), and [HVC](#).

For A64 instructions, see [SVC](#) and [HVC](#).

### ISS encoding for an exception from SMC instruction execution in AArch32 state

This encoding is used by:

- SMC instruction execution in AArch32 state, when SMC is not disabled.  
This is reported in ESR\_EL2 only when the exception is generated because the value of [HCR\\_EL2.TSC](#) is 1.

The ISS encoding for these exceptions is:

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from Non-secure EL1 because [HCR\\_EL2.TSC](#) is 1, the ISS encoding is as shown in the diagram.

#### CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

#### COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

#### CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

- |   |  |
|---|--|
| 0 | The instruction was unconditional, or was conditional and passed its condition code check. |
| 1 | The instruction was conditional, and might have failed its condition code check.           |

#### ———— Note ————

In an implementation in which an SMC instruction that fails its code check is not trapped, this field can always return the value 0.

#### Bits [18:0]

Reserved, RES0.

[Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1858](#) describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes, and [System calls on page D1-1878](#) describes the case where these exceptions are trapped to EL3.

#### ISS encoding for an exception from SMC instruction execution in AArch64 state

This encoding is used by:

- SMC instruction execution in AArch64 state, when SMC is not disabled.  
This is reported in ESR\_EL2 only when the exception is generated because the value of [HCR\\_EL2.TSC](#) is 1.

The ISS encoding for these exceptions is:

#### Bits [24:16]

Reserved, RES0.

### imm16, bits [15:0]

The value of the immediate field from the issued SMC instruction.

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from Non-secure EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

[Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1858](#) describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes, and [System calls on page D1-1878](#) describes the case where these exceptions are trapped to EL3.

### ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

This encoding is used by:

- Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC 0b000000, 0b000001 or 0b000111.

This include all instructions that cause exceptions that are part of the encoding space defined in [System instruction class encoding overview on page C5-313](#), except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.

The ISS encoding for these exceptions is:

#### Bits [24:22]

Reserved, RES0.

#### Op0, bits [21:20]

The Op0 value from the issued instruction.

#### Op2, bits [19:17]

The Op2 value from the issued instruction.

#### Op1, bits [16:14]

The Op1 value from the issued instruction.

#### CRn, bits [13:10]

The CRn value from the issued instruction.

#### Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

#### CRm, bits [4:1]

The CRm value from the issued instruction.

#### Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- |   |   |
|---|---|
| 0 | Write access, including MSR instructions. |
| 1 | Read access, including MRS instructions.  |

For exceptions caused by System instructions, see [System](#) on page C4-215 for the encoding values returned by an instruction.

The following sections describe configuration settings for generating the exception that is reported using EC value 0b011000:

- In [EL1 configurable controls](#) on page D1-1843.
  - [Traps to EL1 of EL0 execution of cache maintenance instructions](#) on page D1-1844.
  - [Traps to EL1 of EL0 accesses to the CTR\\_EL0](#) on page D1-1845.
  - [Traps to EL1 of EL0 execution of DC ZVA instructions](#) on page D1-1846.
  - [Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks](#) on page D1-1846.
  - [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers](#) on page D1-1847.
  - [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers](#) on page D1-1848.
  - [Traps to EL1 of EL0 accesses to the Generic Timer registers](#) on page D1-1849.
  - [Traps to EL1 of EL0 accesses to Performance Monitors registers](#) on page D1-1850.
- In [EL2 configurable controls](#) on page D1-1851.
  - [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers](#) on page D1-1853.
  - [Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions](#) on page D1-1854.
  - [Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions](#) on page D1-1854.
  - [Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions](#) on page D1-1855.
  - [Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register](#) on page D1-1856.
  - [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations](#) on page D1-1857.
  - [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers](#) on page D1-1858.
  - [Trapping to EL2 of Non-secure EL1 accesses to the CPACR\\_EL1 or CPACR](#) on page D1-1862.
  - [Traps to EL2 of Non-secure System register accesses to the trace registers](#) on page D1-1863.
  - [Trapping System register accesses to Debug ROM registers to EL2](#) on page D1-1865.
  - [Trapping System register accesses to powerdown debug registers to EL2](#) on page D1-1866.
  - [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers](#) on page D1-1867.
  - [Trapping general System register accesses to debug registers to EL2](#) on page D1-1866.
  - [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers](#) on page D1-1868.
- In [EL3 configurable controls](#) on page D1-1869.
  - [Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers](#) on page D1-1872.
  - [Trapping to EL3 of EL2 accesses to the CPTR\\_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR\\_EL1 or CPACR](#) on page D1-1873.
  - [Traps to EL3 of all System register accesses to the trace registers](#) on page D1-1874.
  - [Trapping System register accesses to powerdown debug registers to EL3](#) on page D1-1875.
  - [Trapping general System register accesses to debug registers to EL3](#) on page D1-1876.
  - [Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers](#) on page D1-1877.

### **ISS encoding for a IMPLEMENTATION DEFINED exception to EL3**

This encoding is used by:

- IMPLEMENTATION DEFINED exception to EL3.

The ISS encoding for these exceptions is:

#### IMPLEMENTATION DEFINED, bits [24:0]

IMPLEMENTATION DEFINED.

#### ISS encoding for an exception from an Instruction Abort

This encoding is used by:

- Instruction Abort from a lower Exception level.  
Used for MMU faults generated by instruction accesses and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
- Instruction Abort taken without a change in Exception level.  
Used for MMU faults generated by instruction accesses and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

The ISS encoding for these exceptions is:

#### Bits [24:13]

Reserved, RES0.

#### SET, bits [12:11]

Synchronous Error Type. When the RAS Extension is implemented and IFSC is 010000, describes the state of the PE after taking the Instruction Abort exception. The possible values of this field are:

- |    |                           |
|----|---------------------------|
| 00 | Recoverable error (UER).  |
| 01 | Restartable error (UEO).  |
| 10 | Uncontainable error (UC). |
| 11 | Corrected error (CE).     |

#### ————— Note —————

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in an unrecoverable PE state.

This field is RES0 if either:

- The RAS Extension is not implemented.
- The value returned in the IFSC field is not 010000.

#### **FnV, bit [10]**

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0 FAR is valid.

1 FAR is not valid, and holds an UNKNOWN value.

This field is only valid if the IFSC code is 010000. It is RES0 for all other aborts.

#### **EA, bit [9]**

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

#### **Bit [8]**

Reserved, RES0.

#### **S1PTW, bit [7]**

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0 Fault not on a stage 2 translation for a stage 1 translation table walk.

1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

#### **Bit [6]**

Reserved, RES0.

#### **IFSC, bits [5:0]**

Instruction Fault Status Code. Possible values of this field are:

000000 Address size fault, level 0 of translation or translation table base register

000001 Address size fault, level 1

000010 Address size fault, level 2

000011 Address size fault, level 3

000100 Translation fault, level 0

000101 Translation fault, level 1

000110 Translation fault, level 2

000111 Translation fault, level 3

001001 Access flag fault, level 1

001010 Access flag fault, level 2

001011 Access flag fault, level 3

001101 Permission fault, level 1

001110 Permission fault, level 2

001111 Permission fault, level 3

010000 Synchronous external abort, not on translation table walk

011000 Synchronous parity or ECC error on memory access, not on translation table walk

010100 Synchronous external abort, on translation table walk, level 0

010101 Synchronous external abort, on translation table walk, level 1

010110 Synchronous external abort, on translation table walk, level 2

010111 Synchronous external abort, on translation table walk, level 3

011100 Synchronous parity or ECC error on memory access on translation table walk, level 0

011101	Synchronous parity or ECC error on memory access on translation table walk, level 1
011110	Synchronous parity or ECC error on memory access on translation table walk, level 2
011111	Synchronous parity or ECC error on memory access on translation table walk, level 3
110000	TLB conflict abort

All other values are reserved.

When the RAS Extension is implemented, 011000, 011100, 011101, 011110, and 011111 are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on page D4-2109](#).

#### Note

Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

### ISS encoding for an exception from a Data Abort

This encoding is used by:

- Data Abort from a lower Exception level.  
Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
- Data Abort taken without a change in Exception level.  
Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

The ISS encoding for these exceptions is:

#### ISV, bit [24]

Instruction syndrome valid. Indicates whether the syndrome information in ISS[23:14] is valid.

- 0 No valid instruction syndrome. ISS[23:14] are RES0.
- 1 ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults reported in ESR\_EL2 except the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111), including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback.
- AArch32 instructions where the instruction:
  - Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
  - Is not performing register writeback.

— Is not using R15 as a source or destination register.

For these cases, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

ISV is 0 for all faults reported in ESR\_EL1 or ESR\_EL3.

When the RAS Extension is implemented, ISV is 0 for any Synchronous external abort.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

When the RAS Extension is not implemented, the value of ISV on a Synchronous external abort on a stage 2 translation table walk is IMPLEMENTATION DEFINED.

#### SAS, bits [23:22]

Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

00	Byte
01	Halfword
10	Word
11	Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

#### SSE, bit [21]

Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

0	Sign-extension not required.
1	Data item must be sign-extended.

For all other operations this bit is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

#### SRT, bits [20:16]

Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction. If the exception was taken from an Exception level that is using AArch32 then this is the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states on page D1-1888](#).

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

#### SF, bit [15]

Width of the register accessed by the instruction is Sixty-Four. When ISV is 1, the possible values of this bit are:

0	Instruction loads/stores a 32-bit wide register.
1	Instruction loads/stores a 64-bit wide register.

#### ————— Note —————

This field specifies the register width identified by the instruction, not the Execution state.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

#### AR, bit [14]

Acquire/Release. When ISV is 1, the possible values of this bit are:

- 0 Instruction did not have acquire/release semantics.
- 1 Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

#### Bit [13]

Reserved, RES0.

#### SET, bits [12:11]

Synchronous Error Type. When the RAS Extension is implemented and DFSC is 010000, describes the state of the PE after taking the Data Abort exception. The possible values of this field are:

- 00 Recoverable error (UER).
- 01 Restartable error (UEO).
- 10 Uncontainable error (UC).
- 11 Corrected error (CE).

#### ————— Note —————

Software can use this information to determine what recovery might be possible. Taking a synchronous External Abort exception might result in an unrecoverable PE state.

This field is RES0 if either:

- The RAS Extension is not implemented.
- The value returned in the DFSC field is not 010000.

#### FnV, bit [10]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0 FAR is valid.
- 1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 010000. It is RES0 for all other aborts.

#### EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

#### CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

- 0 The Data Abort was not generated by the execution of one of the system instructions identified in the description of value 1.
- 1 The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.

#### S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- 0 Fault not on a stage 2 translation for a stage 1 translation table walk.

1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

#### WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location. The possible values of this bit are:

0 Abort caused by an instruction reading from a memory location.

1 Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- An external abort.
- A fault reported using the DFSC value of 0b110101 that indicates the lack of support for atomic instructions by the memory type.

#### DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

000000 Address size fault, level 0 of translation or translation table base register

000001 Address size fault, level 1

000010 Address size fault, level 2

000011 Address size fault, level 3

000100 Translation fault, level 0

000101 Translation fault, level 1

000110 Translation fault, level 2

000111 Translation fault, level 3

001001 Access flag fault, level 1

001010 Access flag fault, level 2

001011 Access flag fault, level 3

001101 Permission fault, level 1

001110 Permission fault, level 2

001111 Permission fault, level 3

010000 Synchronous external abort, not on translation table walk

011000 Synchronous parity or ECC error on memory access, not on translation table walk

010100 Synchronous external abort, on translation table walk, level 0

010101 Synchronous external abort, on translation table walk, level 1

010110 Synchronous external abort, on translation table walk, level 2

010111 Synchronous external abort, on translation table walk, level 3

011100 Synchronous parity or ECC error on memory access on translation table walk, level 0

011101 Synchronous parity or ECC error on memory access on translation table walk, level 1

011110 Synchronous parity or ECC error on memory access on translation table walk, level 2

011111 Synchronous parity or ECC error on memory access on translation table walk, level 3

100001	Alignment fault
110000	TLB conflict abort
110001	Unsupported atomic hardware update fault, if the implementation includes <a href="#">ARMv8.1-TTHM</a> . Otherwise reserved.
110100	IMPLEMENTATION DEFINED fault (Lockdown)
110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access)
111101	Section Domain Fault, used only for faults reported in the <a href="#">PAR_EL1</a>
111110	Page Domain Fault, used only for faults reported in the <a href="#">PAR_EL1</a>

All other values are reserved.

When the RAS Extension is implemented, 011000, 011100, 011101, 011110, and 011111 are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on page D4-2109](#).

#### Note

Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

### ISS encoding for an exception from a trapped floating-point exception

This encoding is used by:

- Trapped floating-point exception taken from AArch32 state.  
Whether this Exception class is supported is IMPLEMENTATION DEFINED.
- Trapped floating-point exception taken from AArch64 state.  
Whether this Exception class is supported is IMPLEMENTATION DEFINED.

The ISS encoding for these exceptions is:

#### Bit [24]

Reserved, RES0.

#### TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions. The possible values of this bit are:

- 0 The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.

- 1 One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information see [Floating-point exceptions and exception traps on page D1-1831](#).

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating point exception from a vector instruction.

**Note**

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from a vector instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

**Bits [22:11]**

Reserved, RES0.

**VECITR, bits [10:8]**

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

**IDF, bit [7]**

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Input denormal floating-point exception has not occurred.
- 1 Input denormal floating-point exception occurred during execution of the reported instruction.

**Bits [6:5]**

Reserved, RES0.

**IXF, bit [4]**

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Inexact floating-point exception has not occurred.
- 1 Inexact floating-point exception occurred during execution of the reported instruction.

**UFF, bit [3]**

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Underflow floating-point exception has not occurred.
- 1 Underflow floating-point exception occurred during execution of the reported instruction.

**OFF, bit [2]**

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Overflow floating-point exception has not occurred.
- 1 Overflow floating-point exception occurred during execution of the reported instruction.

### DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Divide by Zero floating-point exception has not occurred.
- 1 Divide by Zero floating-point exception occurred during execution of the reported instruction.

### IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Invalid Operation floating-point exception has not occurred.
- 1 Invalid Operation floating-point exception occurred during execution of the reported instruction.

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the **FPCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the **FPSCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

### ISS encoding for an SError interrupt

This encoding is used by:

- SError interrupt.

The ISS encoding for these exceptions is:

### IDS, bit [24]

IMPLEMENTATION DEFINED syndrome. Possible values of this bit are:

- 0 Bits[23:0] of the ISS field are defined in this description.

#### Note

If the RAS Extension is not implemented, this means that bits[23:0] of the ISS field are RES0.

- 1 Bits[23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt.

#### Note

This field was previously called ISV.

### Bits [23:14]

Reserved, RES0.

### IESB, bit [13]

Implicit Error Synchronization Barrier.

This field is part of the RAS Extension in an ARMv8.2 implementation.

The possible values of this field are:

- |   |  |
|---|--|
| 0 | The SError interrupt was either not synchronized by the implicit ErrorSynchronizationBarrier() or not taken immediately. |
| 1 | The SError interrupt was synchronized by the implicit ErrorSynchronizationBarrier() and taken immediately.               |

This field is RES0 if either:

- The implementation is an ARMv8.0 or ARMv8.1 implementation.
- The value returned in the DFSC field is not 010001.

---

**Note**

ARMv8.2 requires the implementation of the RAS Extension.

---

### AET, bits [12:10]

Asynchronous Error Type.

When the RAS Extension is implemented and DFSC is 010001, describes the state of the PE after taking the SError interrupt exception. The possible values of this field are:

- |     |                            |
|-----|----------------------------|
| 000 | Uncontainable error (UC).  |
| 001 | Unrecoverable error (UEU). |
| 010 | Restartable error (UEO).   |
| 011 | Recoverable error (UER).   |
| 110 | Corrected error (CE).      |

All other values are reserved.

If multiple errors are taken as a single SError interrupt exception, the overall state of the PE is reported. For example, if both a Recoverable and Unrecoverable error occurred, the state is Unrecoverable.

---

**Note**

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

---

This field is RES0 if either:

- The RAS Extension is not implemented.
- The value returned in the DFSC field is not 010001.

---

**Note**

ARMv8.2 requires the implementation of the RAS Extension.

---

### EA, bit [9]

External abort type. When the RAS Extension is implemented, this bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

This field is RES0 if either:

- The RAS Extension is not implemented.
- The value returned in the DFSC field is not 010001.

———— **Note** ————

ARMv8.2 requires the implementation of the RAS Extension.

**Bits [8:6]**

Reserved, RES0.

**DFSC, bits [5:0]**

Data Fault Status Code. When the RAS Extension is implemented, possible values of this field are:

000000      Uncategorized.

010001      Asynchronous SError interrupt.

All other values are reserved.

If the RAS Extension is not implemented, this field is RES0.

———— **Note** ————

ARMv8.2 requires the implementation of the RAS Extension.

**ISS encoding for an exception from a Breakpoint or Vector Catch debug exception**

This encoding is used by:

- Breakpoint exception from a lower Exception level.
- Breakpoint exception taken without a change in Exception level.
- Vector Catch exception from AArch32 state.

The only case where a Vector Catch exception is taken to an Exception level that is using AArch64 is when the exception is routed to EL2 and EL2 is using AArch64.

The ISS encoding for these exceptions is:

**Bits [24:6]**

Reserved, RES0.

**IFSC, bits [5:0]**

Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.

For more information about generating these exceptions:

- For exceptions from AArch64, see [Breakpoint exceptions on page D2-1921](#).
- For exceptions from AArch32, see [Breakpoint exceptions on page G2-4470](#) and [Vector Catch exceptions on page G2-4510](#).

**ISS encoding for an exception from a Software Step exception**

This encoding is used by:

- Software Step exception from a lower Exception level.
- Software Step exception taken without a change in Exception level.

The ISS encoding for these exceptions is:

#### ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

- 0 EX bit is RES0.
- 1 EX bit is valid.

See the EX bit description for more information.

#### Bits [23:7]

Reserved, RES0.

#### EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

- 0 An instruction other than a Load-Exclusive instruction was stepped.
- 1 A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

#### IFSC, bits [5:0]

Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.

For more information about generating these exceptions, see [Software Step exceptions on page D2-1956](#).

#### ISS encoding for an exception from a Watchpoint exception

This encoding is used by:

- Watchpoint exception from a lower Exception level.
- Watchpoint exception taken without a change in Exception level.

The ISS encoding for these exceptions is:

#### Bits [24:9]

Reserved, RES0.

#### CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

- 0 The Data Abort was not generated by the execution of one of the system instructions identified in the description of value 1.

- 1 The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The **DC ZVA** instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.

#### Bit [7]

Reserved, RES0.

#### WnR, bit [6]

Write not Read. Indicates whether the abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location. The possible values of this bit are:

- 0 Abort caused by an instruction reading from a memory location.  
1 Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction, this field is set to 0 if a read of the location would have generated a fault, otherwise it is set to 1.

#### DFSC, bits [5:0]

Data Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.

For more information about generating these exceptions, see [Watchpoint exceptions](#) on page D2-1940.

#### ISS encoding for an exception from execution of a Breakpoint instruction

This encoding is used by:

- BKPT instruction execution in AArch32 state.
- BRK instruction execution in AArch64 state.

This is reported in ESR\_EL3 only if a BRK instruction is executed at EL3.

The ISS encoding for these exceptions is:

#### Bits [24:16]

Reserved, RES0.

#### Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary. For the AArch32 BKPT instructions, the comment field is described as the immediate field.

For more information about generating these exceptions, see [Breakpoint Instruction exceptions](#) on page D2-1919.

## D7.2.29 FAR\_EL1, Fault Address Register (EL1)

The FAR\_EL1 characteristics are:

### Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort, PC alignment fault and Watchpoint exceptions that are taken to EL1.

### Configurations

AArch64 System register FAR\_EL1[31:0] is architecturally mapped to AArch32 System register [DFAR](#) (NS).

AArch64 System register FAR\_EL1[63:32] is architecturally mapped to AArch32 System register [IFAR](#) (NS).

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

FAR\_EL1 is a 64-bit register.

### Field descriptions

The FAR\_EL1 bit assignments are:

### Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL1. Exceptions that set the FAR\_EL1 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment faults (EC 0x22), and Watchpoints (EC 0x34 or 0x35). [ESR\\_EL1](#).EC holds the EC value for the exception.

For a synchronous external abort, if the VA that generated the abort was from an address range for which [TCR\\_ELx](#).TBI{<0>1} = 1 for the translation regime in use when the abort was generated, then the top eight bits of FAR\_EL1 are UNKNOWN.

For a synchronous external abort other than a synchronous external abort on a translation table walk, this field is valid only if [ESR\\_EL1](#).FnV is 0, and the FAR\_EL1 is UNKNOWN if [ESR\\_EL1](#).FnV is 1.

For all other exceptions taken to EL1, the FAR\_EL1 is UNKNOWN.

If a memory fault that sets FAR\_EL1 is generated from a data cache maintenance or DC ZVA instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR\_EL1 is taken from an Exception level that is using AArch32, the top 32 bits are all zero, unless the faulting address is generated by a load or store instruction that sequentially increments from address 0xFFFFFFFF. This is an UNPREDICTABLE condition, and in this case the upper 32-bits are set to 0x00000001.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see [Address tagging in AArch64 state on page D4-2006](#).

### Note

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lower address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR\_EL1 is made UNKNOWN on an exception return from EL1.

## Accessing the FAR\_EL1

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
FAR_EL1	11	000	0110	0000	000
FAR_EL12	11	101	0110	0000	000

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
FAR_EL1	x	x	0	-	RW	n/a	RW
FAR_EL1	0	0	1	-	RW	RW	RW
FAR_EL1	0	1	1	-	n/a	RW	RW
FAR_EL1	1	0	1	-	RW	<a href="#">FAR_EL2</a>	RW
FAR_EL1	1	1	1	-	n/a	<a href="#">FAR_EL2</a>	RW
FAR_EL12	x	x	0	-	-	n/a	-
FAR_EL12	0	0	1	-	-	-	-
FAR_EL12	0	1	1	-	n/a	-	-
FAR_EL12	1	0	1	-	-	RW	RW
FAR_EL12	1	1	1	-	n/a	RW	RW

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL3 using the mnemonic FAR\_EL1 or FAR\_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If [HCR\\_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If [HCR\\_EL2](#).TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
  - If [HCR\\_EL2](#).TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

## D7.2.30 FAR\_EL2, Fault Address Register (EL2)

The FAR\_EL2 characteristics are:

### Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort, PC alignment fault and Watchpoint exceptions that are taken to EL2.

### Configurations

AArch64 System register FAR\_EL2[31:0] is architecturally mapped to AArch32 System register [HDFAR](#).

AArch64 System register FAR\_EL2[63:32] is architecturally mapped to AArch32 System register [HIFAR](#).

AArch64 System register FAR\_EL2[31:0] is architecturally mapped to AArch32 System register [DFAR](#) (S) when EL2 is implemented.

AArch64 System register FAR\_EL2[63:32] is architecturally mapped to AArch32 System register [IFAR](#) (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

FAR\_EL2 is a 64-bit register.

### Field descriptions

The FAR\_EL2 bit assignments are:

### Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL2. Exceptions that set the FAR\_EL2 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment faults (EC 0x22), and Watchpoints (EC 0x34 or 0x35). [ESR\\_EL2](#).EC holds the EC value for the exception.

For a synchronous external abort, if the VA that generated the abort was from an address range for which [TCR\\_ELx](#).TBI{<0>|1}> = 1 for the translation regime in use when the abort was generated, then the top eight bits of FAR\_EL2 are UNKNOWN.

For a synchronous external abort other than a synchronous external abort on a translation table walk, this field is valid only if [ESR\\_EL2](#).FnV is 0, and the FAR\_EL2 is UNKNOWN if [ESR\\_EL2](#).FnV is 1.

For all other exceptions taken to EL2, the FAR\_EL2 is UNKNOWN.

If a memory fault that sets FAR\_EL2 is generated from a data cache maintenance or DC ZVA instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR\_EL2 is taken from an Exception level that is using AArch32, the top 32-bits are all zero, unless the faulting address is generated by a load or store instruction that sequentially increments from address 0xFFFFFFFF. This is an UNPREDICTABLE condition, and in this case the upper 32-bits are set to 0x00000001.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see [Address tagging in AArch64 state on page D4-2006](#).

### Note

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lower address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR\_EL2 is made UNKNOWN on an exception return from EL2.

## Accessing the FAR\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
FAR_EL2	11	100	0110	0000	000
FAR_EL1	11	000	0110	0000	000

## Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
FAR_EL2	x	x	0	-	-	n/a	RW
FAR_EL2	0	0	1	-	-	RW	RW
FAR_EL2	0	1	1	-	n/a	RW	RW
FAR_EL2	1	0	1	-	-	RW	RW
FAR_EL2	1	1	1	-	n/a	RW	RW
FAR_EL1	x	x	0	-	<a href="#">FAR_EL1</a>	n/a	<a href="#">FAR_EL1</a>
FAR_EL1	0	0	1	-	<a href="#">FAR_EL1</a>	<a href="#">FAR_EL1</a>	<a href="#">FAR_EL1</a>
FAR_EL1	0	1	1	-	n/a	<a href="#">FAR_EL1</a>	<a href="#">FAR_EL1</a>
FAR_EL1	1	0	1	-	<a href="#">FAR_EL1</a>	RW	<a href="#">FAR_EL1</a>
FAR_EL1	1	1	1	-	n/a	RW	<a href="#">FAR_EL1</a>

This table applies to all instructions that can access this register.

When [HCR\\_EL2.E2H](#) is 1, without explicit synchronization, access from EL2 using the mnemonic FAR\_EL2 or FAR\_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

## D7.2.31 FAR\_EL3, Fault Address Register (EL3)

The FAR\_EL3 characteristics are:

### Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort and PC alignment fault exceptions that are taken to EL3.

### Configurations

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

FAR\_EL3 is a 64-bit register.

### Field descriptions

The FAR\_EL3 bit assignments are:

### Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL3. Exceptions that set the FAR\_EL3 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), and PC alignment faults (EC 0x22). [ESR\\_EL3](#).EC holds the EC value for the exception.

For a synchronous external abort, if the VA that generated the abort was from an address range for which [TCR\\_El3](#).TBI{<0|1>} = 1 for the translation regime in use when the abort was generated, then the top eight bits of FAR\_EL3 are UNKNOWN.

For a synchronous external abort other than a synchronous external abort on a translation table walk, this field is valid only if [ESR\\_EL3](#).FnV is 0, and the FAR\_EL3 is UNKNOWN if [ESR\\_EL3](#).FnV is 1.

For all other exceptions taken to EL3, the FAR\_EL3 is UNKNOWN.

If a memory fault that sets FAR\_EL3 is generated from a data cache maintenance or DC ZVA instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR\_EL3 is taken from an EL using AArch32, the top 32-bits are all zero, unless the faulting address is generated by a load or store instruction that sequentially increments from address 0xffffffff. This is an UNPREDICTABLE condition, and in this case the upper 32-bits are set to 0x00000001.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see [Address tagging in AArch64 state on page D4-2006](#).

### ———— Note ————

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR\_EL3 is made UNKNOWN on an exception return from EL3.

### Accessing the FAR\_EL3

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
FAR_EL3	11	110	0110	0000	000

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
0	0	1	-	-	-	RW
0	1	1	-	n/a	-	RW
1	0	1	-	-	-	RW
1	1	1	-	n/a	-	RW

## D7.2.32 FPEXC32\_EL2, Floating-Point Exception Control register

The FPEXC32\_EL2 characteristics are:

### Purpose

Allows access to the AArch32 register [FPEXC](#) from AArch64 state only. Its value has no effect on execution in AArch64 state.

### Configurations

AArch64 System register FPEXC32\_EL2 is architecturally mapped to AArch32 System register [FPEXC](#).

If EL1 cannot use AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

FPEXC32\_EL2 is a 32-bit register.

### Field descriptions

The FPEXC32\_EL2 bit assignments are:

### EX, bit [31]

Exception bit. In ARMv8, this bit is RAZ/WI.

### EN, bit [30]

Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:

- VMSR accesses to the [FPEXC](#) or [FPSID](#).
- VMRS accesses from the [FPEXC](#), [FPSID](#), [MVFR0](#), [MVFR1](#), or [MVFR2](#).

0 Accesses to the [FPSCR](#), and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are UNDEFINED at all Exception levels.

1 This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- [CPACR](#).cp10, or, if executing at EL0, [CPACR\\_EL1](#).FPEN.
- FPEXC.EN.

- If executing in Non-secure state:
  - [HCPTR](#).TCP10, or if EL2 is using AArch64, [CPTR\\_EL2](#).TFP.
  - [NSACR](#).cp10, or if EL3 is using AArch64, [CPTR\\_EL3](#).TFP.
- For Advanced SIMD instructions only:
  - [CPACR](#).ASEDIS.
  - If executing in Non-secure state, [HCPTR](#).TASE and [NSACR](#).NSTRCDIS.

See the descriptions of the controls for more information.

---

**Note**

---

When executing at EL0 using AArch32:

- If EL1 is using AArch64 then behavior is as if the value of [FPEXC](#).EN is 1.
  - In Non-secure state, if EL2 is using AArch64 and the value of [HCR\\_EL2](#).{RW, TGE} is {1, 1} then behavior is as if the value of [FPEXC](#).EN is 1.
  - In Non-secure state, if EL2 is using AArch64 and the value of [HCR\\_EL2](#).{RW, TGE} is {0, 1} then it is IMPLEMENTATION DEFINED whether the behavior is:
    - As if the value of [FPEXC](#).EN is 1.
    - Determined by the value of [FPEXC32\\_EL2](#).EN, as described in this field description. ARM deprecates using the value of [FPEXC32\\_EL2](#).EN to determine behavior.
- 

#### DEX, bit [29]

Defined synchronous exception on floating-point execution.

This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function `ExecutingCP10or11Instr()` returning TRUE. This field also indicates whether the [FPEXC32\\_EL2](#).TFV field is valid.

The meaning of this bit is:

- |   |   |
|---|---|
| 0 | The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function <code>ExecutingCP10or11Instr()</code> . If <a href="#">FPEXC32_EL2</a> .TFV is RW then it is invalid and UNKNOWN. If <a href="#">FPEXC32_EL2</a> .{IDF, IXF, UFF, OFF, DZF, IOF} are RW then they are invalid and UNKNOWN. |
| 1 | The exception was generated during the execution of an unallocated encoding. <a href="#">FPEXC32_EL2</a> .TFV is valid and indicates the cause of the exception.  |

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.

On an implementation that both does not support trapping of floating-point exceptions and implements the AArch32 [FPSCR](#).{Stride, Len} fields as RAZ, this bit is RES0.

#### FP2V, bit [28]

FPINST2 instruction valid bit. In ARMv8, this bit is RES0.

#### VV, bit [27]

VECITR valid bit. In ARMv8, this bit is RES0.

### TFV, bit [26]

Trapped Fault Valid bit. Valid only when the value of FPEXC.DEX is 1. When valid, it indicates the cause of the exception and therefore whether the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are valid.

- 0 The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFNMS, VMLA, VMLS, VMOV, VMUL, VNEG, VNMLA, VNMLS, VNMUL, VSQRT, or VSUB instruction when one or both of [FPSCR](#).{Stride, Len} was nonzero. If the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are RW then they are invalid and UNKNOWN.
- 1 FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.

When the value of FPEXC.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

On an implementation that supports the trapping of floating-point exceptions and implements [FPSCR](#).{Stride, Len} as RAZ, this bit is RAO/WI.

### Bits [25:11]

Reserved, RES0.

### VECITR, bits [10:8]

Vector iteration count. In ARMv8, this field is RES1.

### IDF, bit [7]

Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while [FPSCR](#).IDE was 1:

- 0 Input denormal exception has not occurred.
- 1 Input denormal exception has occurred.

Input Denormal exceptions can occur only when [FPSCR](#).FZ is 1.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

### Bits [6:5]

Reserved, RES0.

### IXF, bit [4]

Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while [FPSCR](#).IXE was 1:

- 0 Inexact exception has not occurred.
- 1 Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

#### UFF, bit [3]

Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

- 0 Underflow exception has not occurred.
- 1 Underflow exception has occurred.

Underflow trapped exceptions can occur only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

#### OFF, bit [2]

Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

- 0 Overflow exception has not occurred.
- 1 Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

#### DZF, bit [1]

Divide by Zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide by Zero exception occurred while FPSCR.DZE was 1:

- 0 Divide by Zero exception has not occurred.
- 1 Divide by Zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

#### IOF, bit [0]

Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

- 0 Invalid Operation exception has not occurred.
- 1 Invalid Operation exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

### Accessing the FPEXC32\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
FPEXC32_EL2	11	100	0101	0011	000

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

## Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#). Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 0):
  - If CPTR\_EL2.TFP==1, Non-secure accesses to this register from EL2 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 0):
  - If CPTR\_EL2.FPEN==00, Non-secure accesses to this register from EL2 are trapped to EL2.
  - If CPTR\_EL2.FPEN==10, Non-secure accesses to this register from EL2 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR\_EL3.NS == 1) && (HCR\_EL2.E2H == 1) && (HCR\_EL2.TGE == 1):
  - If CPTR\_EL2.FPEN==00, Non-secure accesses to this register from EL2 are trapped to EL2.
  - If CPTR\_EL2.FPEN==10, Non-secure accesses to this register from EL2 are trapped to EL2.
- When EL3 is implemented and is using AArch64:
  - If CPTR\_EL3.TFP==1, accesses to this register from EL2 and EL3 are trapped to EL3.

### D7.2.33 HACR\_EL2, Hypervisor Auxiliary Control Register

The HACR\_EL2 characteristics are:

**Purpose**

Controls trapping to EL2 of IMPLEMENTATION DEFINED aspects of Non-secure EL1 or EL0 operation.

———— **Note** —————

ARM recommends the values in this register do not cause unnecessary traps to EL2 when [HCR\\_EL2](#).{E2H, TGE} = {1, 1}.

**Configurations**

AArch64 System register HACR\_EL2 is architecturally mapped to AArch32 System register [HACR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HACR\_EL2 is a 32-bit register.

**Field descriptions**

The HACR\_EL2 bit assignments are:

**IMPLEMENTATION DEFINED, bits [31:0]**

IMPLEMENTATION DEFINED.

**Accessing the HACR\_EL2**

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:

MSR <systemreg>, <Xt>

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
HACR_EL2	11	100	0001	0001	111

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
0	0	1	-	-	RW	RW
0	1	1	-	n/a	RW	RW
1	0	1	-	-	RW	RW
1	1	1	-	n/a	RW	RW

## D7.2.34 HCR\_EL2, Hypervisor Configuration Register

The HCR\_EL2 characteristics are:

### Purpose

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to EL2.

### Configurations

AArch64 System register HCR\_EL2[31:0] is architecturally mapped to AArch32 System register [HCR](#).

AArch64 System register HCR\_EL2[63:32] is architecturally mapped to AArch32 System register [HCR2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

HCR\_EL2 is a 64-bit register.

### Field descriptions

The HCR\_EL2 bit assignments are:

### Bits [63:39]

Reserved, RES0.

### MIOCNCNCE, bit [38]

Mismatched Inner/Outer Cacheable Non-Coherency Enable, for the Non-secure EL1&0 translation regime.

- 0 For the Non-secure EL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there must be no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.
- 1 For the Non-secure EL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there might be a loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

For more information see [Mismatched memory attributes](#) on page B2-118.

This field can be implemented as RAZ/WI.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2](#).{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

### TEA, bit [37]

Route synchronous External Abort exceptions to EL2. If the RAS Extension is implemented, the possible values of this bit are:

- 0 Do not route synchronous External Abort exceptions from Non-secure EL0 and EL1 to EL2.
- 1 Route synchronous External Abort exceptions from Non-secure EL0 and EL1 to EL2, if not routed to EL3.

This bit resets to zero on a Warm reset into AArch32 state.

When the RAS Extension is not implemented, this field is RES0.

### TERR, bit [36]

Trap Error record accesses. If the RAS Extension is implemented, the possible values of this bit are:

- 0 Do not trap accesses to error record registers from Non-secure EL1 to EL2.
- 1 Accesses to the ER\* registers from Non-secure EL1 generate a Trap exception to EL2.

This bit resets to zero on a Warm reset into AArch32 state.

When the RAS Extension is not implemented, this field is RES0.

### TLOR, bit [35]

#### *In ARMv8.2 and ARMv8.1*

Trap LOR registers. Traps accesses to the [LORSA\\_EL1](#), [LOREA\\_EL1](#), [LORN\\_EL1](#), [LORC\\_EL1](#), and [LORID\\_EL1](#) registers from Non-secure EL1 to EL2.

- 0 This control does not cause any instructions to be trapped.
- 1 Non-secure EL1 accesses to the LOR registers are trapped to EL2.

When [HCR\\_EL2](#).TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

#### *In ARMv8.0.*

Reserved, RES0.

### E2H, bit [34]

#### *In ARMv8.2 and ARMv8.1*

EL2 Host. Enables a configuration where a Host Operating System is running in EL2, and the Host Operating System's applications are running in EL0.

- 0 EL2 is running a hypervisor.

1 EL2 is running a Host Operating System.

For information on the behavior of this bit see [Behavior of HCR\\_EL2.E2H](#) on page D4-2098.

This bit is permitted to be cached in a TLB.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of HCR\_EL2.

**In ARMv8.0.**

Reserved, RES0.

#### ID, bit [33]

Stage 2 Instruction access cacheability disable. For the Non-secure EL1&0 translation regime, when [HCR\\_EL2.VM](#)==1, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

0 This control has no effect on stage 2 of the Non-secure EL1&0 translation regime.

1 For the Non-secure EL1&0 translation regime, forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of HCR\_EL2.

This bit has no effect on the EL2, EL2&0, or EL3 translation regimes.

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2.{E2H, TGE}](#) is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

#### CD, bit [32]

Stage 2 Data access cacheability disable. For the Non-secure EL1&0 translation regime, when [HCR\\_EL2.VM](#)==1, this control forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

0 This control has no effect on stage 2 of the Non-secure EL1&0 translation regime for data accesses and translation table walks.

1 For the Non-secure EL1&0 translation regime, forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of HCR\_EL2.

This bit has no effect on the EL2, EL2&0, or EL3 translation regimes.

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2.{E2H, TGE}](#) is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

#### RW, bit [31]

Execution state control for lower Exception levels:

0 Lower levels are all AArch32.

1 The Execution state for EL1 is AArch64. The Execution state for EL0 is determined by the current value of [PSTATE.nRW](#) when executing at EL0.

If all lower Exception levels cannot use AArch32 then this bit is RAO/WI.

In an implementation that includes EL3, when [SCR\\_EL3.NS](#)==0, the PE behaves as if this bit has the same value as the [SCR\\_EL3.RW](#) bit for all purposes other than a direct read or write access of HCR\_EL2.

The RW bit is permitted to be cached in a TLB.

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2.{E2H, TGE}](#) is {1, 1}, this field behaves as 1 for all purposes other than a direct read of the value of this bit.

### TRVM, bit [30]

Trap Reads of Virtual Memory controls. Traps Non-secure EL1 reads of the virtual memory control registers to EL2, from both Execution states. The registers for which read accesses are trapped are as follows:

Non-secure EL1 using AArch64: [SCTLR\\_EL1](#), [TTBR0\\_EL1](#), [TTBR1\\_EL1](#), [TCR\\_EL1](#), [ESR\\_EL1](#), [FAR\\_EL1](#), [AFSR0\\_EL1](#), [AFSR1\\_EL1](#), [MAIR\\_EL1](#), [AMAIR\\_EL1](#), [CONTEXTIDR\\_EL1](#).

Non-secure EL1 using AArch32: [SCTLR](#), [TTBR0](#), [TTBR1](#), [TTBCR](#), [TTBCR2](#), [DACR](#), [DFSR](#), [IFSR](#), [DFAR](#), [IFAR](#), [ADFSR](#), [AIFSR](#), [PRRR](#), [NMRR](#), [MAIR0](#), [MAIR1](#), [AMAIR0](#), [AMAIR1](#), [CONTEXTIDR](#).

- |   |   |
|---|---|
| 0 | This control does not cause any instructions to be trapped.                               |
| 1 | Non-secure EL1 read accesses to the specified Virtual Memory controls are trapped to EL2. |

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

### HCD, bit [29]

HVC instruction disable. Disables Non-secure state execution of HVC instructions, from both Execution states.

- |   |   |
|---|---|
| 0 | HVC instruction execution is enabled at EL2 and Non-secure EL1.   |
| 1 | HVC instructions are UNDEFINED at EL2 and Non-secure EL1. Any resulting exception is taken to the Exception level at which the HVC instruction is executed. |

#### ———— Note ————

HVC instructions are always UNDEFINED at EL0.

This bit is only implemented if EL3 is not implemented. Otherwise, it is RES0.

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

### TDZ, bit [28]

Trap [DC ZVA](#) instructions. Traps Non-secure EL0 and EL1 execution of [DC ZVA](#) instructions to EL2, from AArch64 state only.

- |   |   |
|---|---|
| 0 | This control does not cause any instructions to be trapped.   |
| 1 | In AArch64 state, any attempt to execute a <a href="#">DC ZVA</a> instruction at Non-secure EL1, or at Non-secure EL0 when the instruction is not UNDEFINED at EL0, is trapped to EL2. Reading the <a href="#">DCZID_EL0</a> returns a value that indicates that <a href="#">DC ZVA</a> instructions are not supported. |

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2.{E2H, TGE}](#) is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

### TGE, bit [27]

Trap General Exceptions, from Non-secure EL0.

- |   |  |
|---|--|
| 0 | This control has no effect on execution at EL0.  |
| 1 | When the value of <a href="#">SCR_EL3.NS</a> is 0, this control has no effect on execution at EL0.<br>When the value of <a href="#">SCR_EL3.NS</a> is 1, in all cases: <ul style="list-style-type: none"> <li>• All exceptions that would be routed to EL1 are routed to EL2.</li> </ul> |

- The [SCTLR\\_EL1.M](#) field, or the [SCTLR.M](#) field if EL1 is using AArch32, is treated as being 0 for all purposes other than returning the result of a direct read of [SCTLR\\_EL1](#) or [SCTLR](#).
- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.

When the value of [SCR\\_EL3.NS](#) is 1 and the value of [HCR\\_EL2.E2H](#) is 0, additionally:

- The [HCR\\_EL2.{FMO, IMO, AMO}](#) fields are treated as being 1 for all purposes other than a direct read or write access of [HCR\\_EL2](#).
- The [MDCR\\_EL2.{TDRA, TDOSA, TDA, TDE}](#) fields are treated as being 1 for all purposes other than returning the result of a direct read of [MDCR\\_EL2](#).

For information on the behavior of this bit when [E2H](#) is 1, see *Behavior of [HCR\\_EL2.E2H](#)* on page D4-2098.

[HCR\\_EL2.TGE](#) must not be cached in a TLB.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

#### TVM, bit [26]

Trap Virtual Memory controls. Traps Non-secure EL1 writes to the virtual memory control registers to EL2, from both Execution states. The registers for which write accesses are trapped are as follows:

Non-secure EL1 using AArch64: [SCTLR\\_EL1](#), [TTBR0\\_EL1](#), [TTBR1\\_EL1](#), [TCR\\_EL1](#), [ESR\\_EL1](#), [FAR\\_EL1](#), [AFSR0\\_EL1](#), [AFSR1\\_EL1](#), [MAIR\\_EL1](#), [AMAIR\\_EL1](#), [CONTEXTIDR\\_EL1](#).

Non-secure EL1 using AArch32: [SCTLR](#), [TTBR0](#), [TTBR1](#), [TTBCR](#), [TTBCR2](#), [DACR](#), [DFSR](#), [IFSR](#), [DFAR](#), [IFAR](#), [ADFSR](#), [AIFSR](#), [PRRR](#), [NMRR](#), [MAIR0](#), [MAIR1](#), [AMAIR0](#), [AMAIR1](#), [CONTEXTIDR](#).

- |   |   |
|---|---|
| 0 | This control does not cause any instructions to be trapped.   |
| 1 | Non-secure EL1 write accesses to the specified EL1 virtual memory control registers are trapped to EL2. |

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

#### TTLB, bit [25]

Trap TLB maintenance instructions. Traps Non-secure EL1 execution of TLB maintenance instructions to EL2, from both Execution states. This applies to the following instructions:

Non-secure EL1 using AArch64: [TLBI VMALLE1IS](#), [TLBI VAE1IS](#), [TLBI ASIDE1IS](#), [TLBI VAAE1IS](#), [TLBI VALE1IS](#), [TLBI VAALE1IS](#), [TLBI VMALLE1](#), [TLBI VAE1](#), [TLBI ASIDE1](#), [TLBI VAAE1](#), [TLBI VALE1](#), [TLBI VAALE1](#).

Non-secure EL1 using AArch32: [TLBIALLIS](#), [TLBIMVAIS](#), [TLBIASIDIS](#), [TLBIMVAIS](#), [TLBIMVALIS](#), [TLBIMVAALIS](#), [ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#), [TLBIALL](#), [TLBIMVA](#), [TLBIASID](#), [TLBIMVAA](#), [TLBIMVAL](#), [TLBIMVAAL](#).

- |   |  |
|---|--|
| 0 | This control does not cause any instructions to be trapped.                                |
| 1 | Non-secure EL1 execution of the specified TLB maintenance instructions are trapped to EL2. |

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

## TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions at Non-secure EL1 or EL0 using AArch64, and at Non-secure EL1 using AArch32, to EL2. This applies to the following instructions:

Non-secure EL0 using AArch64: [IC IVAU](#), [DC CVAU](#). However, if the value of [SCTLR\\_EL1.UCI](#) is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.

Non-secure EL1 using AArch64: [IC IVAU](#), [IC IALLU](#), [IC IALLUIS](#), [DC CVAU](#).

Non-secure EL1 using AArch32: [ICIMVAU](#), [ICIALLU](#), [ICIALLUIS](#), [DCCMVAU](#).

### Note

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- [IC IALLUIS](#) and [IC IALLU](#) are always UNDEFINED at EL0 using AArch64.
- [ICIMVAU](#), [ICIALLU](#), [ICIALLUIS](#), and [DCCMVAU](#) are always UNDEFINED at EL0 using AArch32.

0 This control does not cause any instructions to be trapped.

1 Non-secure execution of the specified instructions is trapped to EL2.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2](#).{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

## TPCP, bit [23]

### In ARMv8.2

Trap data or unified cache maintenance instructions that operate to the Point of Coherency or Persistence. Traps execution of those cache maintenance instructions at Non-secure EL1 or EL0 using AArch64, and at Non-secure EL1 using AArch32, to EL2. This applies to the following instructions:

Non-secure EL0 using AArch64: [DC CIVAC](#), [DC CVAC](#), [DC CVAP](#). However, if the value of [SCTLR\\_EL1.UCI](#) is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.

Non-secure EL1 using AArch64: [DC IVAC](#), [DC CIVAC](#), [DC CVAC](#), [DC CVAP](#).

Non-secure EL1 using AArch32: [DCIMVAC](#), [DCCIMVAC](#), [DCCMVAC](#).

### Note

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- [DC IVAC](#) is always UNDEFINED at EL0 using AArch64.
- [DCIMVAC](#), [DCCIMVAC](#), and [DCCMVAC](#) are always UNDEFINED at EL0 using AArch32.

0 This control does not cause any instructions to be trapped.

1 Non-secure execution of the specified instructions is trapped to EL2.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

If [HCR\\_EL2](#).{E2H, TGE} is set to {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

**Note**

In previous versions of the architecture this bit was named TPC. From ARMv8.2 this bit is named TPCP.

**In ARMv8.1 and ARMv8.0.**

Trap data or unified cache maintenance instructions that operate to the Point of Coherency. Traps execution of those cache maintenance instructions at Non-secure EL1 or EL0 using AArch64, and at Non-secure EL1 using AArch32, to EL2. This applies to the following instructions:

Non-secure EL0 using AArch64: [DC CIVAC](#), [DC CVAC](#). However, if the value of [SCTLR\\_EL1.UCI](#) is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.

Non-secure EL1 using AArch64: [DC IVAC](#), [DC CIVAC](#), [DC CVAC](#).

Non-secure EL1 using AArch32: [DCIMVAC](#), [DCCIMVAC](#), [DCCMVAC](#).

**Note**

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- [DC IVAC](#) is always UNDEFINED at EL0 using AArch64.
- [DCIMVAC](#), [DCCIMVAC](#), and [DCCMVAC](#) are always UNDEFINED at EL0 using AArch32.

0 This control does not cause any instructions to be trapped.

1 Non-secure execution of the specified instructions is trapped to EL2.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2.{E2H, TGE}](#) is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

**TSW, bit [22]**

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps execution of those cache maintenance instructions at Non-secure EL1 using AArch64, and at Non-secure EL1 using AArch32, to EL2. This applies to the following instructions:

Non-secure EL1 using AArch64: [DC ISW](#), [DC CSW](#), [DC CISW](#).

Non-secure EL1 using AArch32: [DCISW](#), [DCCSW](#), [DCCISW](#).

**Note**

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0 This control does not cause any instructions to be trapped.

1 Non-secure execution of the specified instructions is trapped to EL2.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

**TACR, bit [21]**

Trap Auxiliary Control Registers. Traps Non-secure EL1 accesses to the Auxiliary Control Registers to EL2, from both Execution states. This applies to the following register accesses:

- Non-secure EL1 using AArch64: [ACTLR\\_EL1](#).
- Non-secure EL1 using AArch32: [ACTLR](#) and, if implemented, [ACTLR2](#).

0 This control does not cause any instructions to be trapped.

1 Non-secure EL1 accesses to the specified registers are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

#### TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps Non-secure EL1 accesses to the encodings reserved for IMPLEMENTATION DEFINED functionality to EL2. This applies to the following register accesses:

AArch64: The following reserved encoding spaces:

- IMPLEMENTATION DEFINED system instructions, which are accessed using SYS and SYSL, with  $CRn == \{11, 15\}$ .
- IMPLEMENTATION DEFINED System registers, which are accessed using MRS and MSR with the [S3\\_<op1>\\_<Cn>\\_<Cm>\\_<op2>](#) register name.

AArch32: MCR and MRC instructions accessing the following encodings:

- All coproc==p15,  $CRn==c9$ ,  $opc1 == \{0-7\}$ ,  $CRm == \{c0-c2, c5-c8\}$ ,  $opc2 == \{0-7\}$ .
- All coproc==p15,  $CRn==c10$ ,  $opc1 == \{0-7\}$ ,  $CRm == \{c0, c1, c4, c8\}$ ,  $opc2 == \{0-7\}$ .
- All coproc==p15,  $CRn==c11$ ,  $opc1==\{0-7\}$ ,  $CRm == \{c0-c8, c15\}$ ,  $opc2 == \{0-7\}$ .

When the value of [HCR\\_EL2.TIDCP](#) is 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from Non-secure EL0 is trapped to EL2. If it is not, then it is UNDEFINED, and any attempt to access it from Non-secure EL0 generates an exception that is taken to EL1.

0 This control does not cause any instructions to be trapped.

1 Non-secure EL1 accesses to or execution of the specified encodings reserved for IMPLEMENTATION DEFINED functionality are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

#### TSC, bit [19]

Trap SMC instructions. Traps Non-secure EL1 execution of SMC instructions to EL2, from both Execution states.

0 This control does not cause any instructions to be trapped.

1 Any attempt to execute an SMC instruction at Non-secure EL1 using AArch64 or Non-secure EL1 using AArch32 is trapped to EL2, regardless of the value of [SCR\\_EL3.SMD](#).

In AArch32 state, the ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

If EL3 is not implemented, this bit is RES0.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

#### TID3, bit [18]

Trap ID group 3. Traps Non-secure EL1 reads of the following registers to EL2:

AArch64: [ID\\_PFR0\\_EL1](#), [ID\\_PFR1\\_EL1](#), [ID\\_DFR0\\_EL1](#), [ID\\_AFR0\\_EL1](#), [ID\\_MMFR0\\_EL1](#), [ID\\_MMFR1\\_EL1](#), [ID\\_MMFR2\\_EL1](#), [ID\\_MMFR3\\_EL1](#), [ID\\_ISAR0\\_EL1](#), [ID\\_ISAR1\\_EL1](#), [ID\\_ISAR2\\_EL1](#), [ID\\_ISAR3\\_EL1](#), [ID\\_ISAR4\\_EL1](#), [ID\\_ISAR5\\_EL1](#), [MVFR0\\_EL1](#), [MVFR1\\_EL1](#), [MVFR2\\_EL1](#), [ID\\_AA64PFR0\\_EL1](#), [ID\\_AA64PFR1\\_EL1](#), [ID\\_AA64DFR0\\_EL1](#), [ID\\_AA64DFR1\\_EL1](#), [ID\\_AA64ISAR0\\_EL1](#), [ID\\_AA64ISAR1\\_EL1](#), [ID\\_AA64MMFR0\\_EL1](#), [ID\\_AA64MMFR1\\_EL1](#), [ID\\_AA64MMFR2\\_EL1](#), [ID\\_AA64AFR0\\_EL1](#), [ID\\_AA64AFR1\\_EL1](#),

ID\_AA64ZFR0\_EL1 (where SVE is implemented), and ID\_MMFR4\_EL1, except that if ID\_MMFR4\_EL1 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to ID\_MMFR4\_EL1 are trapped.

It is IMPLEMENTATION DEFINED whether this field traps MRS accesses to encodings in the following range that are not already mentioned in this field description:

- Op0 == 3, op1 == 0, CRn == c0, CRm == {c2-c7}, op2 == {0-7}.

AArch32: ID\_PFR0, ID\_PFR1, ID\_DFR0, ID\_AFR0, ID\_MMFR0, ID\_MMFR1, ID\_MMFR2, ID\_MMFR3, ID\_ISAR0, ID\_ISAR1, ID\_ISAR2, ID\_ISAR3, ID\_ISAR4, ID\_ISAR5, MVFR0, MVFR1, MVFR2, and ID\_MMFR4, except that if ID\_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to ID\_MMFR4 are trapped.

MRC access to any of the following encodings are also trapped:

- coproc==p15, opc1 == 0, CRn == c0, CRm == {c3-c7}, opc2 == {0,1}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == 2.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {4,5}.

It is IMPLEMENTATION DEFINED whether this bit traps MRC accesses to the following encodings:

- coproc==p15, opc1 == 0, CRn == c0, CRm == c2, opc2 == 7.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == {3-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == {c4, c6, c7}, opc2 == {2-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {2, 3, 6, 7}.

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 read accesses to ID group 3 registers are trapped to EL2.

In an implementation that includes EL3, when the value of SCR\_EL3.NS is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of HCR\_EL2.

When HCR\_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

## TID2, bit [17]

Trap ID group 2. Traps the following register accesses to EL2:

AArch64:

- Non-secure EL1 reads of CTR\_EL0, CCSIDR\_EL1, CLIDR\_EL1, and CSSELR\_EL1.
- Non-secure EL0 reads of CTR\_EL0, except that if the value of SCTLRL\_EL1.UCT is 0 then EL0 reads of CTR\_EL0 are UNDEFINED and any resulting exception takes precedence over this trap.
- Non-secure EL1 writes to CSSELR\_EL1.

AArch32:

- Non-secure EL1 reads of the CTR, CCSIDR, CLIDR, and CSSELR.
- Non-secure EL1 writes to the CSSELR.

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 and EL0 accesses to ID group 2 registers are trapped to EL2.

In an implementation that includes EL3, when the value of SCR\_EL3.NS is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of HCR\_EL2.

When ARMv8.1-VHE is implemented, and the value of HCR\_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

## TID1, bit [16]

Trap ID group 1. Traps Non-secure EL1 reads of the following registers are trapped to EL2:

AArch64: REVIDR\_EL1, AIDR\_EL1.

AArch32: [TCMTR](#), [TLBTR](#), [REVIDR](#), [AIDR](#).

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 read accesses to ID group 1 registers are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

#### TID0, bit [15]

Trap ID group 0. Traps the following register accesses to EL2:

AArch64: None.

AArch32:

- Non-secure EL1 reads of the [JIDR](#).
- If the [JIDR](#) is RAZ from Non-secure EL0, Non-secure EL0 of the [JIDR](#).
- Non-secure EL1 reads of the [FPSID](#).

#### Note

- It is IMPLEMENTATION DEFINED whether the [JIDR](#) is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0 then any resulting exception takes precedence over this trap.
- The [FPSID](#) is not accessible at EL0 using AArch32.
- Writes to the [FPSID](#) are ignored, and not trapped by this control.

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 read accesses to ID group 0 registers are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

In an AArch64-only implementation, this bit is RES0.

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2.{E2H, TGE}](#) is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

#### TWE, bit [14]

Traps Non-secure EL0 and EL1 execution of WFE instructions to EL2, from both Execution states.

0 This control does not cause any instructions to be trapped.

1 Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by [SCTLR.nTWE](#) or [SCTLR\\_EL1.nTWE](#).

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

#### Note

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2.{E2H, TGE}](#) is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

### TWI, bit [13]

Traps Non-secure EL0 and EL1 execution of WFI instructions to EL2, from both Execution states.

- |   |   |
|---|---|
| 0 | This control does not cause any instructions to be trapped.   |
| 1 | Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by <a href="#">SCTLR.nTWI</a> or <a href="#">SCTLR_EL1.nTWI</a> . |

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

#### Note

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2](#).{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

### DC, bit [12]

This field is permitted to be cached in a TLB.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2](#).{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this field.

### BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from Non-secure EL1 or Non-secure EL0:

- |    |                 |
|----|-----------------|
| 00 | No effect       |
| 01 | Inner Shareable |
| 10 | Outer Shareable |
| 11 | Full system     |

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2](#).{E2H, TGE} is {1, 1}, this field behaves as 0b00 for all purposes other than a direct read of the value of this bit.

### FB, bit [9]

Force broadcast. Causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

AArch32: [BPIALL](#), [TLBIALL](#), [TLBIMVA](#), [TLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#), [ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [TLBIMVAA](#), [ICIALLU](#), [TLBIMVAL](#), [TLBIMVAAL](#).

AArch64: [TLBI VMALLE1](#), [TLBI VAE1](#), [TLBI ASIDE1](#), [TLBI VAAE1](#), [TLBI VALE1](#), [TLBI VAALE1](#), [IC IALLU](#).

- |   |   |
|---|---|
| 0 | This field has no effect on the operation of the specified instructions.  |
| 1 | When one of the specified instruction is executed at Non-secure EL1, the instruction is broadcast within the Inner Shareable shareability domain. |

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

#### VSE, bit [8]

Virtual SError interrupt.

0 This mechanism is not making a virtual SError interrupt pending.

1 A virtual SError interrupt is pending because of this mechanism.

The virtual SError interrupt is only enabled when the value of [HCR\\_EL2.{TGE, AMO}](#) is {0, 1}.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

#### VI, bit [7]

Virtual IRQ Interrupt.

0 This mechanism is not making a virtual IRQ pending.

1 A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of [HCR\\_EL2.{TGE, IMO}](#) is {0, 1}.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

#### VF, bit [6]

Virtual FIQ Interrupt.

0 This mechanism is not making a virtual FIQ pending.

1 A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of [HCR\\_EL2.{TGE, FMO}](#) is {0, 1}.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

#### AMO, bit [5]

Physical SError Interrupt routing.

0 When executing at Non-secure Exception levels below EL2, physical SError Interrupts are not taken to EL2.

When the value of [HCR\\_EL2.TGE](#) is 0, if the PE is executing at EL2 using AArch64, physical SError Interrupts are not taken unless they are routed to EL3 by the [SCR\\_EL3.EA](#) bit.

Virtual SError interrupts are disabled.

1 When executing at any Exception level in Non-secure state:

- Physical SError interrupts are taken to EL2 unless they are routed to EL3.
- If [HCR\\_EL2.TGE](#)==0 then Virtual SError interrupts are enabled in the Non-secure state.

If the value of [HCR\\_EL2.TGE](#) is 1:

- Regardless of the value of the AMO bit, when executing in Non-secure state, physical Asynchronous External Aborts and SError Interrupts target EL2 unless they are routed to EL3.
- When [ARMv8.1-VHE](#) is not implemented, or if [HCR\\_EL2.E2H](#) is 0, this field behaves as 1 for all purposes other than a direct read of the value of this bit.
- When [ARMv8.1-VHE](#) is implemented and [HCR\\_EL2.E2H](#) is 1, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information, see [Asynchronous exception routing on page D1-1834](#).

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

#### IMO, bit [4]

Physical IRQ Routing.

- 0 When executing at Non-secure Exception levels below EL2, physical IRQ interrupts are not taken to EL2.
- When the value of [HCR\\_EL2.TGE](#) is 0, if the PE is executing at EL2 using AArch64, physical IRQ interrupts are not taken unless they are routed to EL3 by the [SCR\\_EL3.IRQ](#) bit.
- Virtual IRQ interrupts are disabled.
- 1 When executing at any Exception level in Non-secure state:
- Physical IRQ interrupts are taken to EL2 unless they are routed to EL3.
  - If [HCR\\_EL2.TGE](#)==0 then Virtual IRQ interrupts are enabled in Non-secure state.

If the value of [HCR\\_EL2.TGE](#) is 1:

- Regardless of the value of the IMO bit, when executing in Non-secure state, physical IRQ Interrupts target EL2 unless they are routed to EL3.
- When [ARMv8.1-VHE](#) is not implemented, or if [HCR\\_EL2.E2H](#) is 0, this field behaves as 1 for all purposes other than a direct read of the value of this bit.
- When [ARMv8.1-VHE](#) is implemented and [HCR\\_EL2.E2H](#) is 1, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information, see [Asynchronous exception routing](#) on page D1-1834.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

#### FMO, bit [3]

Physical FIQ Routing.

- 0 When executing at Non-secure Exception levels below EL2, physical FIQ interrupts are not taken to EL2.
- When the value of [HCR\\_EL2.TGE](#) is 0, if the PE is executing at EL2 using AArch64, physical FIQ interrupts are not taken unless they are routed to EL3 by the [SCR\\_EL3.FIQ](#) bit.
- Virtual FIQ interrupts are disabled.
- 1 When executing at any Exception level in Non-secure state:
- Physical FIQ interrupts are taken to EL2 unless they are routed to EL3.
  - If [HCR\\_EL2.TGE](#)==0 then Virtual FIQ interrupts are enabled in Non-secure state.

If the value of [HCR\\_EL2.TGE](#) is 1:

- Regardless of the value of the FMO bit, when executing in Non-secure state, physical FIQ Interrupts target EL2 unless they are routed to EL3.
- When [ARMv8.1-VHE](#) is not implemented, or if [HCR\\_EL2.E2H](#) is 0, this field behaves as 1 for all purposes other than a direct read of the value of this bit.
- When [ARMv8.1-VHE](#) is implemented and [HCR\\_EL2.E2H](#) is 1, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

For more information, see [Asynchronous exception routing](#) on page D1-1834.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

### PTW, bit [2]

Protected Table Walk. In the Non-secure EL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs then the value of this bit determines the behavior:

- 0 The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.
- 1 The memory access generates a stage 2 Permission fault.

This field is permitted to be cached in a TLB.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

### SWIO, bit [1]

Set/Way Invalidation Override. Causes Non-secure EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way:

- 0 This control has no effect on the operation of data cache invalidate by set/way instructions.
- 1 Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When the value of this bit is 1:

AArch32: [DCISW](#) performs the same invalidation as a [DCCISW](#) instruction.

AArch64: [DC ISW](#) performs the same invalidation as a [DC CISW](#) instruction.

This bit can be implemented as RES1.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [HCR\\_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

### VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the Non-secure EL1&0 translation regime. Possible values of this bit are:

- 0 Non-secure EL1&0 stage 2 address translation disabled.
- 1 Non-secure EL1&0 stage 2 address translation enabled.

When the value of this bit is 1, data cache invalidate instructions executed at Non-secure EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the [HCR\\_EL2.SWIO](#) bit.

This bit is permitted to be cached in a TLB.

In an implementation that includes EL3, when the value of [SCR\\_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR\\_EL2](#).

When [ARMv8.1-VHE](#) is implemented, and the value of [HCR\\_EL2.{E2H, TGE}](#) is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

## Accessing the HCR\_EL2

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
HCR_EL2	11	100	0001	0001	000

## Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
0	0	1	-	-	RW	RW
0	1	1	-	n/a	RW	RW
1	0	1	-	-	RW	RW
1	1	1	-	n/a	RW	RW

## D7.2.35 HPFAR\_EL2, Hypervisor IPA Fault Address Register

The HPFAR\_EL2 characteristics are:

### Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to EL2.

### Configurations

AArch64 System register HPFAR\_EL2[31:0] is architecturally mapped to AArch32 System register [HPFAR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

HPFAR\_EL2 is a 64-bit register.

### Field descriptions

The HPFAR\_EL2 bit assignments are:

Execution at EL1 or EL0 makes HPFAR\_EL2 become UNKNOWN.

### Bits [63:44]

Reserved, RES0.

### FIPA[51:48], bits [43:40]

#### In ARMv8.2

Extension to FIPA[47:12]. See FIPA[47:12] for more details.

#### In ARMv8.1 and ARMv8.0.

Reserved, RES0.

### FIPA[47:12], bits [39:4]

Bits [47:12] of the faulting intermediate physical address. When [ARMv8.2-LPA](#) is implemented, and 52-bit addresses and a 64KB translation granule are in use, FIPA[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, FIPA[51:48] are RES0.

The HPFAR\_EL2 is written for:

- Translation or Access faults in the second stage of translation.
- An abort in the second stage of translation performed during the translation table walk of a first stage translation, caused by a Translation fault, an Access flag fault, or a Permission fault.
- A stage 2 Address size fault.

### Note

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

For all other exceptions taken to EL2, this register is UNKNOWN.

In an implementation or a translation granule that does not support [ARMv8.2-LPA](#), the upper bits of this field are RES0.

### Bits [3:0]

Reserved, RES0.

### Accessing the HPFAR\_EL2

This register can be read using MRS with the following syntax:

MRS <Xt>, <systemreg>

This register can be written using MSR (register) with the following syntax:
